[5692].—**Caats of Carvings.**—"J. B." writes so furiously respecting Mr. Harry Jikes' useful information that one is almost inclined to think "Brown" himself, first member of the firm "J. B." says Mr. Jikes entirely ignores, could not have more indignantly corrected the oversight. But, with a vivid recollection before me of a pleasant trip, not a very long time ago, into Devonshire, I can fully substantiate what Mr. Jikes has told us. Newton Abbott, Chudleigh, Henneock, and, indeed, all the other little places "J. B." refers to, lay within a radius of three or four miles of one another, and it is quite sufficient to know that pipeclay is obtained in South Devon, without defining any particular set of little towns and villages such as "J. B." appears to deem necessary. It would be much more interesting if "J. B." who appears to know all about it, instead of repeating what Mr. Jikes has already told us as to pipeclay being decomposed granite, would explain by what curious transformation granite becomes clay. This will be useful and instructive, and, by so-doing, "J. B." will render infinitely more public

service than by making petty corrections and giving particularly dry quotations as to what the shipping dues may be of "Brown," Jones or Robinson.—YORKSHIRE.

[5697].—**Weight of Wrought Iron Girder.**—In my anxiety to give every information I possibly can, I have hurriedly worked out the calculation, as desired by "Learner," having just had my attention called to his question:—

20	0	= 30	0	in. web	=	7	ft. 6	in. one inch thick.
20	0	= 15	0	in. flange	=	7	6	" "
20	0	= 15	0	in. flange	=	11	3	" "
4	20	0	= 53	4	in. angle iron	=	20	0
							46	3
6	100	= 360	in. rivets 2	in.				
				long = 75	ft. of			
				round bar			3	26
							17	2
								0

If he refers to the second edition of my work "Quantities" he will find the amount so stated. The item for rivets is three to a foot, 20ft. long = 60, and six times 60 for the 6 rows.—BANISTER FLETCHER.

[5697].—**Weight of Wrought Iron Girder.**—Many thanks for "R. J.'s" explanation of the item for rivets. I note a misprint in my reply 500; 6 egg and tongue carving should be 5'0"; 6' egg, &c.—BROTHER LEARNER.

LEGAL INTELLIGENCE.

A HEAVY FINE FOR BREACH OF BUILDING REGULATIONS.—District Surveyor for East Hackney (North) v. Henry Shipp, heard at Worship-street Police-court, on the 6th of March, 1879, before Mr. Bushby.—On the 9th March, 1878, an order had been made for the defendant, within one month, to amend certain irregularities to four dwellings, Lockhurst-street, Clapton Park, but on the 19th February, 1879, the order had not been complied with. This was proved by the District Surveyor, and the defendant was fined £100, having been previously fined £56 6s. in respect of the same matter.

NEGLECTING TO GIVE BUILDING NOTICES.—At Lambeth Police-court on Thursday, the 6th inst., Frederick Vyner, of Tintern-street, Brixton, was summoned by Mr. Parsons, district manager, for neglecting to give him proper notice, under the Metropolitan Building Act, in respect of certain houses in Tintern-street. The district surveyor explained that it was the practice with a certain class of builders to commence the erection of buildings and carry them up to a certain stage, and then suspend operations for some length of time, after which work was resumed, ostensibly by the original builder, but really by mortgages or other persons who were unknown to the district surveyor, and who in consequence found himself greatly impeded in enforcing the provisions of the Act. These arrangements were carried out by the agency and assistance of working men like the defendant, who thought it very great fun to plead entire ignorance of everything when questioned by the district surveyor or his assistants. They, on being questioned, never knew who they were working for, nor where their employer lived. He called Mr. W. H. Rawlings, his assistant, who fully proved the case, showing that defendant stated he was working for a Mr. Iles, but that he did not know his employer's address. The work was commenced a year since, suspended for some months, and then resumed. Afterwards, when a bench summons was about to be served on him, he said he was working for the mortgagee, a Mr. Bartlett, but no notices were sent the surveyor as to a change of builders. The magistrate (Mr. Ellison) said the Act provided that notice should be given to the surveyor after work had been suspended, or if the builder was changed, and the Act defined the "builder" as not only the master builder, but any person engaged in doing any work on the building. Defendant would be fined £3, and 12s. 6d. costs, and he might apply to the mortgagee to repay it.

REFUSAL OF CERTIFICATE.—STEVENSON v. WATSON.—This was a case which came before the Common Pleas Division last week upon demurrer to a statement of claim, and it raised a question of considerable importance as to the liability of architects in relation to their duties under building contracts between master and servant. The plaintiff was a builder employed under a contract to erect a large building as a temperance hall near Nottingham, and the defendant was an architect employed by the building owners to superintend the execution of the works. The defendant had previously prepared plans and bills of quantities of artificers' work, and these plans and bills formed the basis of the contract which was executed between the plaintiff and the building owners. The bill of quantities contained also two further stipulations—first, that should there be more or less measure than was there given, there would respectively be an addition to or deduction from the contract; and, secondly, all measurements were to be made in the same manner as the quantities had been taken, and all additions or deductions

were to be priced at the same rate by the architect. The contract then set out the following conditions, which appeared in the statement of claim:—"The architect might order any additions to or deductions from the contract without in any way vitiating the contract, and the amount of such additions or deductions was to be ascertained by him in the same manner as the quantities had been measured, and at the same rate as they had been priced at. Another clause provided that all disputes between the plaintiff as contractor and the building owners, which might arise during the progress of the works, were to be settled by the defendant, whose decision was to be final and binding on all parties; and lastly, it was provided that the plaintiff was to be paid on certificates, signed by the architect, of the work done and money which was due. The claim then stated that from time to time the architect did certify accordingly until the works were completed. A final statement of accounts was then sent in by the plaintiff to the defendant, showing that, after adding to the contract the amount of the additions ordered by the defendant and deducting the amount of the deductions ordered by the defendant, and making all necessary corrections to errors discovered in the bill of quantities, a net balance was owing to the plaintiff of £1,616 6s. 7d.; but the defendant, without calling upon the plaintiff for an explanation, certified only for an excess over the estimate of £251, and thus did not use that due care and skill in ascertaining what was really due to the plaintiff, on the faith and expectation of which he had been induced to sign the contract, but knowingly and negligently certified for an inferior sum. The claim concluded that upon complaint made by the plaintiff the defendant refused to give any reasons or to reconsider the matter. To this statement of claim the defendant demurred, on the ground that the statement showed the defendant to be in the position of an arbitrator who had acted and declared his decision, and that, as no fraud or mala fides was suggested, no action against him was maintainable. Lord Coleridge described the action as one of a kind which had been vainly brought over and over again—viz., for the negligent performance of a duty in the execution of which the exercise of judgment and opinion was necessary. The contract only required that disputes between the contracting parties should be settled by the defendant, and he was in no way bound to enter into any reasons for any decision he arrived at, having regard to the relations that existed between him and the plaintiff. Mr. Justice Denman concurred. The duty of the defendant, in his judgment, was to perform what he had to do honestly, and there was no suggestion in the statement of claim of any mala fides or dishonesty. The nature of his duties was strictly analogous to those of an arbitrator, and not, as had been suggested, to those of a mere appraiser. Ordinary acquaintance with building contracts showed that an architect could not be regarded as a mere ester-up of figures, and ought not, therefore, to be held liable for negligence when a mistake in figures or measurements occurred. The demurrer was therefore allowed, but it is understood that the question will yet be carried to the Court of Appeal.

WATER SUPPLY AND SANITARY MATTERS.

LEAMINGTON.—The new waterworks at Leamington were opened on Tuesday. Hitherto Leamington has derived its supply from the river Leam; but the water of that stream becoming unfit for use, works have been constructed, at a cost of upwards of £25,000, for obtaining water from a deep boring in the red sandstone. The water is lifted by two engines, of 65 horse-power each, into the reservoirs on the Newbold Hills, from whence it gravitates over the town.

WEYMOUTH.—At a meeting of the Corporation of Weymouth last week, the Mayor presiding, a report on the sanitary condition of the borough, from Professor W. H. Corfield, M.A., was read and considered. Professor Corfield had been appointed to make an investigation of the harbour, backwater, and surroundings, with a view of giving his opinion as to any alleged cause of nuisance. It was a very exhaustive report. Professor Corfield is strongly of opinion the sewage of the town should be taken entirely out of the backwater and harbour into the sea. A joint report from Dr. Tizard, the medical officer of health, and several other medical men was read, endorsing Professor Corfield's opinion, whilst letters were received from Dr. Lush and Dr. Wood also approving his suggestions, and urging that the sewage should be carried out to sea. The following resolution was agreed to, on the proposal of Mr. Councillor Nangle, seconded by Mr. Councillor Howard:—"Resolved, that Dr. Corfield, having amongst other things been asked, by order of this Authority, 'What suggestions can be made by way of remedying the offensive smells complained of?' this Authority do adopt the words of the reply thereto, viz., to 'Divert the sewage entirely from the backwater and harbour; and that this

Authority do instruct the town clerk to call a committee meeting of the whole Urban Sanitary Authority of this borough, on one day of the ensuing week, and from week to week if necessary, to consider and settle means for arriving at a scheme to carry the same reply or suggestion into effect."

Our Office Table.

At the annual meeting of the Royal Birmingham Society of Artists, on Saturday last, Sir F. Leighton, the President of the Royal Academy, was elected President of the Birmingham Society in the room of the late Sir Francis Grant. Owing to his advanced age and inability to attend the meetings, Mr. Peter Hollins (much to the regret of his colleagues) some time ago intimated his desire to resign the vice-presidency, and Mr. J. H. Chamberlain was on Saturday elected to that office. Mr. E. R. Taylor, head master of the Birmingham School of Art, was elected a member of the society; and Mrs. G. J. Whitfield (formerly Miss Florence Westwood) was elected an honorary member—the first election of a lady in the history of the society.

A PARLIAMENTARY paper has been issued containing the annual report of the Director of the National Gallery to the Lords Commissioners of the Treasury for the year 1878. During that period the following pictures were purchased out of Government funds:—"Mary Magdalene approaching the Sepulchre," by Giovanni Girolamo Savoldo; "St. Helena—Vision of the Invention of the Cross," by Paul Veronese; "The Agony in the Garden," by a painter of the Umbrian School; "The Adoration of the Magi," attributed to Filippino Lippi (or Botticelli?); "The Nativity," by Sandro Botticelli; "Portrait of a Gentleman," by Francia Bigio; "A Landscape" (snow scene), by Mulready; and "A Landscape" (Gordale Scar, Yorkshire), by James Ward, R.A. The following were purchased out of the "Lewis" Fund:—"Portrait of a Gentleman," by a Flemish painter of the 16th century; landscape (river and rocks), by W. J. Muller; "Portrait of a Gentleman" (three-quarter length), by Catharina van Hemessen; and a fragment of a composition in fresco, by Ambrogio Lorenzetti. Among the additions to the Gallery may be noted "A Canon and his Patron Saints," by Gheeraert David, bequeathed by Mr. William Benoni White, and "A Portrait of the Rev. Sir Henry Bate Dudley, Bart.," and seven studies of landscape in crayon, all by Gainsborough, presented by Mr. Thomas Birch Wolfe. The total number of pictures now contained in the public rooms of the gallery is 1,008, 607 of which are covered with glass.

READERS desirous of comparing at a glance the respective prices of roofing slates of all sizes per 1,200, per 1,000, and per square, will find themselves very materially assisted by a handy little "Roofing Slate Ready Reckoner," published by Mr. Alfred Baker, of 51, North-road, Brighton. The cost is only sixpence, and the amount will soon be saved sixtyfold in time by the use of the table, which is printed on card for office use, or on paper for the pocket.

From the report of Mr. Haywood, engineer and surveyor to the Commissioners of Sewers for the City of London, of works executed during 1878, we learn that a large number of street improvements were executed, including the completion of the Cheapside and Poultry improvement by the setting back of the block of houses between Old Jewry and Ironmonger-lane. Specimens of Poletti and Dimf's patent pavement, and of Dennison's wood and iron pavement, both laid in Beech-street, were taken up and replaced by wood paving; the former had been worn into holes and the blocks had broken, while the latter appeared slippery and dangerous. Dennison's leaden disc pavement in Cornhill was taken up two months after being laid down, and replaced by Limmer's asphalt, the leaden discs having become worn through or pressed out from the asphalt by the traffic, and the specimens of Stone's patent footway pavement in King William-street were taken up after six years' use, having become worn hollow and very inconvenient. There have recently been laid down in Shoe-lane, near Farringdon Market, specimens of Davison's patent iron and asphalt pavement and Dennison's noiseless granite pavement, which are at present under trial. Reference is made to the great changes which have been made in the carriage-way pavements of the City during the past ten years by the substitution of various forms of asphalt and wood paving for granite, and Mr. Haywood states that at the end of 1878 there were laid down in the City, 9,688 yards of compressed asphalt, 1,611 yards of mastie ditto, and 11,164 yards of wood paving, making a total of about 12½ miles of these classes of street-paving now in use.

A CORRESPONDENT of the *Northampton Mercury* tells a good story of the building speculations of the unreformed corporation of Higham Ferrers. He says: "Our venerable corporation launched into the building trade, and placed themselves in the hands of builders with a really charming amount of trustfulness. Advertisements were issued inviting plans for a number of cottages to fill a certain piece of ground. Plans and estimates were sent in and one was accepted. The builder, however, refused to sign the contract. The corporation then made a fresh start, and employed a person to draw up plans and specifications. They then again invited tenders for the buildings, either in one or more blocks (the plan was to build in five blocks). One of the tenders received for a certain number of houses was £95 per house, while another tender for the whole lot was £120 per house. The corporation preferred the tender at £120. According to the plans, the houses were to be spouted, and the front spouts were to have a pipe to bring down the water between every two cottages. This has been done, but as there is no drain to take off the water it has for the past twelve months been running into the foundations of the houses. It has now, however, been resolved that the front spouts shall be discontinued, and the whole of the spouting altered so that the water may be taken round to the back of the houses and discharged into the sewer. What the cost of this will be of course we do not yet know. But the

coup de grâce has just been performed. The plans show a road on the south side of the houses about six feet wide. This has been twice approved of by the corporation, and the road, which has been partly made, will cost about £20. There is no outlet, and before the road was finished the corporation built up the entrance, so that here is a good road blocked at both ends!"

CHUBB'S

WROUGHT IRON DOORS,

Fire and Thief-Resisting Strong Rooms, Safes, and Iron Linings. CHUBB'S PATENT LOCKS.

THREE PRIZE MEDALS

And Honourable Mention at PARIS EXHIBITION, 1878. Illustrated Price Lists post-free.

CHUBB & SON, Makers to the Bank of England, 128, Queen Victoria-street, St. Paul's, E.C.; and 68, St. James's-street, Pall Mall, London.—(Advrt.)

Lamplough's Pyretic Saline is refreshing, most agreeable, and the preventive of FEVERS, RHEUMATISM, SMALL-POX, SCARF, DISEASES, and many other spring and summer ailments. Sold by chemists throughout the world, and the Maker, 113, Holborn Hill. Use no substitute.—(Advrt.)

ROOFING SLATES.

Reduction in Prices.

Send for price list to THOMAS R. ROBERTS, Slate Merchant, Conway, before ordering elsewhere. Slate slabs, gills, hearthstones, ridges, cisterns, and all other kind of slate work very cheap.—(Advrt.)

CHIPS.

Negotiations have been opened between the Corporation and the Waterworks Company at Colchester for the purchase of the works by the Council, as the urban authority of the borough, at from 23 to 28 years' purchase on the net profits of the company.

New Board Schools at Longton were opened on Monday week. The building is in the domestic Gothic style. The architect was Mr. T. P. Hulse, and the contractor, Mr. W. Collis, both of Longton.

At a vestry meeting recently held at Gamlingay, Cambridgeshire, it was decided to restore the parish church, which is in a greatly dilapidated state, and over £3,000 was promised in the room towards the cost.

The Ipswich Fine Art Exhibition, recently closed has been a success. The amount already realised is £600, and the number of pictures sold was 162. The visitors were more numerous than those of last year by about a thousand.

A new Wesleyan chapel was recently opened at Banff. It is Gothic in style, and measures internally 55ft. by 29ft. 6in., accommodating 259 worshippers. At the rear are a session house and hall. The buildings were designed by Mr. Ormiston, of Edinburgh, and have cost about £1,200.

At the Hartlepool County Petty Sessions, last week, a case was heard which tested the right of local authorities to charge upon tenants the cost of the water supply, when that previously existing had been found sufficient. After hearing the case fully, the bench made an order for the payment of the amount, with costs.

Mr. Joseph Smith, of Cricklade, has been elected surveyor of that town in succession to the late Mr. George Fawkes, who for many years held the appointment.

CHAPPUIS' PATENTS

FOR

REFLECTING LIGHT.—DAYLIGHT REFLECTORS

OF EVERY DESCRIPTION, ALSO

ARTIFICIAL LIGHT REFLECTORS.

P. E. CHAPPUIS, Patentee. Factory, 69, Fleet-street, London, E.C.

N.B.—DIAGRAMS AND PROSPECTUSES ON APPLICATION.

MEETINGS FOR THE ENSUING WEEK.

- MONDAY.**—Society of Arts, Canto Lecture, No. V. "Dwelling Houses: Their Sanitary Construction and Arrangements," by Dr. Cortfield. 8 p.m.
Institution of Surveyors.—Paper by H. J. Castle, sen., on "Contributive Values." 8 p.m.
- TUESDAY.**—Society of Arts. Paper by Jas. Bradshaw, of Manchester, on "Africa, or Paramount Necessity for the Future Prosperity of the Leading Industries of England." 8 p.m.
- WEDNESDAY.**—Society of Arts. W. Mattieu Williams on "Econometrical Gardens for Londoners." 8 p.m.
British Archaeological Association. Papers by H. Syer Cuming on "Ancient Thimbles," and by Rev. Prebendary Seath on "Roman Inscription found at Bath." 8 p.m.
- THURSDAY.**—Society for the Fine Arts. S. W. Kershaw on "Early Art in Books and Manuscripts." 8 p.m.
- SATURDAY.**—Royal Institution. Seymour Hayden on "Etching."

HELLIWELL'S Patented NEW SYSTEM

OF AIR & WATER-TIGHT IMPERISHABLE GLAZING.

All Woodwork is covered, and no outside Painting is required. Old Roofs Re-glazed. Any one can repair or take in pieces.

"It is suitable for Railway Stations, Mills, Weaving Sheds, &c., but is specially applicable to Conservatories, Plant Houses, and Orchard Houses, and we should be very much inclined to try the system. It is certainly worth looking to."—*Builder*.

"And will, in our opinion, supersede any other similar system before the public."—*Building News*.

"It seems to meet the end in view more nearly than anything we have seen yet."—*The Field*.

"7, Mark-lane, London, Nov. 14, 1878.

"Dear Sir,—I cannot see what testimonial you can require from me than the fact that I have taken off all my putty glazing and removed Rendie's work to replace it with yours; any one seeing the two systems would say that yours is far the superior, and that nothing yet out can touch it.—Yours, W. R. PATERSON. T. W. Helliwell, Esq., Brighouse."

For Estimates, Drawings, or Particulars, apply to the Patentee,

T. W. HELLIWELL, Brighouse, Yorkshire;

or, 19, Parliament-street, London.—[ADVT.]

WHITLAND ABBEY GREEN SLATES

These SLATES are of a grey green tint, are stout, and made in all sizes. A large stock available for immediate delivery. For further particulars (with a list of important buildings covered) apply to the Managers, Clynderwen, R.S.O., Carmarthenshire.—[ADVT.]

Holloway's Pills and Ointment present the readiest and most reasonable means of removing hereditary, constitutional, and chronic disorder, associated with impure blood and unhealthy skin. Scoury, scorbutic affections, unseemly eruptions, enlarged glands, and other blemishes, yield to these purifying remedies, which eradicate the seeds of the complaint, and avert mischief.—[ADVT.]

HIGH-CLASS VARNISHES.

READER BROTHERS, Tower Varnish Works, Wolverhampton, respectfully invite attention to their Varnishes for House Painters, Decorators, and Builders, which will be found of uniform excellence, and for elasticity, lustre, and durability all that can be desired. They would direct special attention to their Extra Hard-Drying Varnishes for church seats, and seats of schools and public buildings, which for hard-drying, brilliancy and wear are unsurpassed.—[ADVT.]

A new public building, to be known as the St. George's Hall, is about to be built at Kendal from the designs of Mr. John Thompson. The contracts of Messrs. D. and J. Thoms, builders, and of Messrs. Thwaites and Son, joiners, have been accepted for the erection of the building.

The public inauguration of an additional water supply for the town of Leven, N.B., took place on Saturday.

Trade News.

WAGES MOVEMENT.

BELFAST.—The master builders, on the 1st of August last, gave notice that they would reduce the wages of the stonecutters by 2s. 3d. per week, the proposed reduction to take effect on the 1st of November. Taking into account the extreme depression of trade and other circumstances, the men assented to the masters' proposition, and the reduction was accordingly made. It appears that shortly afterwards another notice was served on the stonecutters, intimating that the master builders had resolved to make a further reduction of 2s. 3d. per week in their wages, the notice to expire on the 1st of March. On Friday week the notice expired; but a threatened dispute was averted by concessions being made on both sides, whereby a present reduction of $\frac{1}{2}$ d. an hour was agreed to and extension of boundary, with a prospective reduction of $\frac{1}{2}$ d. per hour at the expiry of another three months. The men accordingly agree to accept 7d. per hour until the 1st of June, when they will receive 6 $\frac{1}{2}$ d. per hour, fifty-four hours being the working week.

DUNFERMLINE.—The Dunfermline operative masons have now resumed work on the masters' terms—viz., 6d. per hour. Within the last six months they have been compelled to accept three reductions of wages, ranging from 9d. to 6d. per hour.

NORTH WALES SLATE TRADE.—After many months of almost unparalleled slackness a slight improvement is at last perceptible in the slate trade of North Wales. At Mr. Assheton Smith's quarries at Llanberis, where some 6,000 hands are employed, the working days have this week been extended from three to four, and it is hoped that at the next monthly letting, this day week, there will be a further extension of a day, if not full time. At Lord Penrhyn's Bethesda quarries the working days are still restricted to four weekly, but the orders for shipments at Bangor Port, Carnarvon, and Port Madoc, the outlet for the Festiniog quarrying district, are increasing. Many quarrymen are availing themselves of the pecuniary assistance extended by the North Wales Quarrymen's Union to intending emigrants.

PERTH.—Intimation has been received by a number of painters in Perth that their wages are to be advanced from 6d. to 6 $\frac{1}{2}$ d. per hour. The slaters have commenced work at a reduction of $\frac{1}{2}$ d. per hour.

Doulting Freestone and Ham Hill Stone

of best quality. Prices, delivered at any part of the United Kingdom, given on application to

CHARLES FRANK,

Norton-sub-Hamdon, Ilminster, Somerset.

Agent: Mr. E. CRICKMAY, 4, Agar-street, London, W.C.—[ADVT.]

TENDERS

BRADFORD.—For the erection of an iron bridge over the Lancashire and Yorkshire Railway, at Ripley-street, for the town council of Bradford:—

Woodiwise, Isaac (accepted) ... £447 2 3

BRADFORD.—For the construction of a sewer and road at Oak-lane, for the Bradford Town Council:—

Smith and Carter (accepted) ... £949 15 4

BENACRE.—For Benacre Rectory, Suffolk. Mr. R. Makilwaine Phipson, F.S.A., architect and diocesan surveyor:—

Cornish and Gaymer	£2,087 0 0
Downing	2,016 0 0
Morris	1,940 0 0
Hawes	1,820 0 0
Grimwood (accepted)	1,755 0 0

BOURNEMOUTH.—For new Congregational Church at East Cliff, Bournemouth. Messrs. Kemp, Welch, and Pinder, architects:—

Stroud	£6,274 0 0

George	4,689 0 0
Sharland and Griffin	4,975 0 0
Lawson and Stanley	4,398 15 0
Brown	4,200 0 0
Pike (accepted)	4,013 0 0

DUBLIN.—For additions to Blackheath, Clontarf, for Gibson Black, Esq. Mr. Thomas Drew, R.H.A., architect. Quantities by Messrs. Patterson and Kempster:—

Millard, T.	£3,794 16 8
(No credit for old materials.)			
Collen Bros.	3,635 18 0
Beckett, J. and W.	3,600 0 0
Pemberton, T.	3,600 0 0

ELLAND.—For the curbing, channelling, and repairing of James-street, for the Local Board of Elland, West Riding of Yorkshire. Mr. Richard Horsfall, surveyor:—

Jagger, S. and W. (accepted) ... £294 0 0

[Lowest of eight tenders received, of which the highest amounted to £412 10s. 8d.]

HASTINGS.—For new roads, sewers, &c., at West Hill, Hastings, for G. Clement, and A. L. Sayer, Esqs. Messrs. Cross and Wells, and A. G. Colpoys, Hastings and St. Leonards, architects. Quantities by Messrs. Cross and Wells:—

King	£1,400 0 0
Longhurst	1,312 0 0

NOTTING HILL.—For the erection of an infirmary at Notting Hill for the guardians of St. Marylebone. The whole of the works to be executed in two years. Messrs. H. Saxon Snell and Sons, 22, Southampton-buildings, W.C., architects:—

Mowlem and Co.	£117,343 0 0
Braid and Co.	116,850 0 0
Lovett, H.	115,760 0 0
Perry and Co.	115,000 0 0
Cowland, Bros.	113,915 0 0
Crockett, W.	113,794 0 0
Shaw, G.	110,875 0 0
Wall, Bros., (accepted)	109,000 0 0
Chappell, J. T.	108,860 0 0

KENSAL NEW TOWN.—For making up the roadways of Lancelfield, Herries, Beethoven, Mozart, and Dart-streets, Kensal New Town, for the Chelsea Vestry:—

Matthews, Wm., of Westbourne-park (accepted) ... £2,865 0 0

[Five tenders were received, of which the highest was £4,555, and the lowest the one accepted.]

KENLEY.—For alterations and additions to a house at Kenley near Caterham. Mr. Horace T. Bonner, Lewis-ham, S.E., architect:—

Burman	£950 0 0
Kirk, G.	835 0 0
MacCowan	830 0 0
Higgs	797 0 0

LADYWELL.—For factory and stabling, Ladywell, S.E. Mr. Horace T. Bonner, Lewisham, architect:—

Somerville and Hill	£987 0 0
Hart	972 0 0
Staines and Son	936 0 0
Burman	910 0 0
Kirk, G.	875 0 0
Smeaton	859 0 0
Jerrard	847 0 0

LONDON.—For repairs at the Licensed Victuallers' Asylum, Old Kent-road. Mr. W. Hurran, Chairman.

Mr. W. F. Potter, architect:—

Pritchard, W. H.	£367 10 0
Wood, B. T.	365 0 0
Butler, G. W.	322 0 0
Hayworth, S.	284 0 0
F. Hersee (accepted)	258 9 0

ZINC ROOFING

FIXED COMPLETE.

F. BRABY & CO.,

ESTABLISHED 1837,

THE MANUFACTURING AGENTS OF THE VIEILLE MONTAGNE CO.

PATENT SOLID UNSOLDERED RIDGE PLATES FOR ITALIAN OR PLAIN ZINC ROOFING.

BY THE ADOPTION OF THIS METHOD THE USE OF SOLDER IS ENTIRELY DISPENSED WITH, AND CONSEQUENTLY THE DANGER INCURRED BY THE USE OF FIRE-POTS IS AVOIDED.

THE COST IS LESSENED AND THE DURABILITY INCREASED. ESTIMATES FOR ZINC DORMERS, FLATS, &c.

FITZROY WORKS, 356 TO 369, EUSTON ROAD, LONDON.

ALSO AT DEPTFORD, LIVERPOOL, GLASGOW & CYPRUS.

THE BUILDING NEWS.

LONDON, FRIDAY, MARCH 21, 1879.

GOTHIC ARCHITECTURE IN THE CITY.

GOTHIC architecture still enjoys popularity in our City street buildings. If it has recently given place, in many instances, to a style which conforms more readily to real or supposed business wants, or to the prevailing fashion for "picturesqueness," it still continues to assert itself. In Moorgate-street, at the corner of London Wall, a large and costly pile of offices have lately been erected in the Venetian-Gothic style. There are certainly few streets in the City which are less interesting generally as regards architecture, altogether lacking historical associations, and possessing no striking modern buildings. Anything vigorous and racy is a relief, and the architect of the building we have mentioned (Mr. Bradbear) has evidently been led to this conclusion. Tower Chambers, as the block of offices is called, is a somewhat florid structure, of a type common in Manchester and the United States. The two fronts, of stone, are enriched by a specious kind of ornamentation, in which the windows, with red granite shafts, vary from the flat segment to the lancet pointed trefoil. Polished red shafts, supported on carved corbels, adorn the upper story, which is crowned by a lofty iron cresting of showy design. The corner, which is circular, is finished by a lofty entablature of pointed form, covered with zinc. In the façades we have an astonishing variety in the fenestration. The ground story, to be let as shops, is divided by pilasters carrying flat moulded arches, or, rather, apologies for arches. We cannot imagine why square heads were not used, seeing that the arches are of very slight camber, apparently pointed segments. The circular corner, however, is spanned in one opening after a truly acrobatic fashion; we presume it is stable, though it certainly does not look so; and we can only describe it by asking our readers to imagine a very flat pointed arch of stone, about 10ft. wide, constructed over a window circular on plan. Of course it is not the fault of the arch that it looks exceedingly weak under a tower of smaller openings, with their piers and mullions resting upon it. A singular absence of gradation marks the upper story windows. The first floor have lights in pairs inclosed by pointed arches of segmental form, the tympana of which are strangely cut by a straight label member. The next tier of windows are square-headed trefoils, and the upper ones acutely pointed trefoiled; all have jamb shafts of red Aberdeen. But the centre bays on each front are quite unlike the others; the first-floor windows have profusely carved trefoil-headed tympana, above which is an oriel supported on winged dragons, the effect of which is extremely crowded and incoherent in the upper stories. The oriel looks crushing over the elaborate three-light windows below, and there is a painful want of connection and congruity in the design. All this is intensified by a whimsical variety of ornament in the parapet, the pattern of which displays two very different kinds of panelling, one round and the other square. The only reflection, after looking at such an amazing effort to produce diversity is, that Venetian Gothic has its votaries who prefer redundancy to moderation, profusion and luxuriant detail to chasteness or refined elegance. But we meet with the taste in other buildings of the style. In the plethora of florid ornament, carving and colour characteristic of

the style resides its very recommendation to the taste of the many. The sterner forms of Northern Gothic have never taken the firm root of the more ornate species, or that which Mr. Ruskin has aptly, in his "Stones of Venice," designated as the "efflorescence of decay." We see nowhere in these Gothic effusions of style the all-pervading unity in variety which is the peculiar property of true architecture—everything is frittered or carved to gratify an ill-tempered fancy, and the carver's conceits are as fulsome as they are feeble. To return to Tower Chambers, the building internally is arranged with a central hall and stone staircase, with an iron scroll balustrade of "loud" design, and this feature is certainly not improved by the very bizarre coloured glass in the flat fanlight at the top. The pointed arches and capitals, in which the carver has done his best to advertise his art, are we cannot say of such a kind that we should wish to see the style more largely employed. The floors are let as offices, and from the very convenient position of the building will speedily be let, the rents varying from £25 on the third-floor for small rooms, to £250 for the corner room on the first-floor.

In Aldersgate-street, at the corner of Long-lane, another important structure in a Gothic dress is in progress, from the designs of Messrs. Bateman and Corser. It is destined for the "Manchester Hotel," being undertaken by the Manchester Hotel Company. In this case a less pretentious and more national kind of Gothic has been chosen, namely, the Tudor—red brick, with stone in the windows and dressings, being employed. As to the selection of style, we need but confess that Late Gothic, despite its vagaries and weaknesses, has more claim to be employed for an hotel than any other earlier phase; its forms, features, and ornamentation adapt themselves well to domestic requirements, and we are not obliged to submit to such an extravagant or capricious feature as a row of sharply-pointed arches, the apices of which very uncomfortably rest below a level stair's landing, and the foliage of whose caps threaten to knock one's head or hat every time one of the rooms is entered. Confining our remarks to the exterior, we may say that the building occupies an important corner block opposite the Aldersgate Street Metropolitan Railway Station, a bold rounded corner joining the two fronts. The ground story forms an arcaded row of what is intended for shops; here the panelling in spandrels and the carving in caps have an evidently weak appearance. The first, second, and third floor windows form vertical bays, separated by strings and panel-work, and small balconettes to the third story windows. The windows are two-light and have traceried heads, the third-floor range being pointed with tracery of Perpendicular character. The upper row are square label-headed, with ogee-curved under-arches to the lights. There are two tiers of dormers; the lowest tier rising above the cornice and parapet. It would have been, perhaps, more correct, if not agreeable to the eye, if the whole of the four main windows had been connected vertically instead of showing pointed arches over those of the third floor. Angle stone buttresses, forming pinnacles, flank the lower windows; these and the drops to the carved stone corbels of balconettes, and the gable pinnacles, are a trifle over-florid, if not weak—a quality that strikes us in the detail generally. At the angle a projecting oriel, four stories in height, appears, and the angle roof will be pronounced by a clock turret. There is an evident weakness in the ground-story treatment towards Aldersgate-street and Long-lane. Internally the work is not sufficiently advanced to allow us to form any opinion of the architectural result; though there will be large coffee and smoking rooms

on the ground floor and the customary accommodation provided in large hotels. A stone stairs of geometrical design is provided in the centre of building, with lifts adjoining.

CONCRETE PIPES.

A PAMPHLET just issued by Messrs. E. and F. N. Spon throws some light upon the vexed question of the use of concrete pipes at Bournemouth. It consists of a series of reports, the last of which is dated 27th January, 1879. The concrete pipes are 2ft. diameter, and were laid in the winter of 1877. In the report of Mr. Creeke, the consulting surveyor to the Bournemouth Improvement Commissioners, the thickness of the pipes is stated to be 1½in. In another report, the thickness is said to be 1½in., and in another 1½in. Perhaps it is best to take the thickness as being 1½in., as Mr. Creeke gives it, he being the official person concerned.

We have heard from time to time, during the last twelve months, amusing stories of how the laying of this sewer was being superintended by a committee from the Board, and of differences of opinion on questions of engineering practice; but none of these appear in the pamphlet before us, written by Messrs. Henry Sharp, Jones, and Co., the makers of the concrete pipes, who have taken a more dignified view of the case than to refer, even, to any such proceedings, beyond saying that their effect has been unfortunate to them and detrimental to the ratepayers of Bournemouth. They have been induced to vindicate in this pamphlet the manufacture and use of concrete pipes for sewage purposes, and to put the facts before the public in the hope that not only the quality and character of their rock concrete tubes will be understood, but that they themselves will be justified against the charge that they represent their manufactures to be that which they are not found to be in practice. They do not insinuate any malevolent intention on the part of the Commissioners or their advisers in refusing to continue the use of the concrete pipes; but they express extreme regret that the Commissioners should have condemned in such unqualified terms the kind of pipes which their own surveyor recommended to them—a kind of pipes, moreover, which the inspector of the Local Government Board who held the preliminary inquiry was aware the Improvement Commissioners intended to use, and who remarked that such pipes were being extensively used in other parts of the country for sewerage purposes.

After the pipes had been laid in Knyveton-road, the sewer was required (for some reason not stated) to be laid at a lower level, and they were uncovered, and many of them were found to be broken—split longitudinally. Then came guesses at the cause of this. Was it the nature of the materials of which the pipes were made? That seems to have been the first guess, and some pieces of a broken pipe were sent to Mr. Henry Reid, consulting engineer and chemist, for his opinion as to their durability, meaning thereby their durability at Bournemouth, where it is said the water contains no lime; but, as Mr. Reid exceeded his instructions, and proceeded to inquire into the process of manufacture, and to test the capacity of the concrete pipes to resist any mechanical shock or wear to which they might be subjected, the Commissioners did not receive his report kindly. They asked for reports from Mr. Donaldson, of Reading, and Mr. Ponton, of Parkstone, Dorset, who both reported unfavourably of the concrete pipes.

Mr. Creeke states the conclusions he has arrived at, after seeing the pipes taken out of the trench in Knyveton-road, premising that he reports under a full apprehension that his conclusions will be subjected to

criticism, both by local practical men and by many of his own profession, for the issues, he says, are of very considerable professional and commercial moment: and he feels also his own responsibility to the Board. After stating his conclusions, he thinks the Board fully justified in withdrawing from the further use of these pipes; but, very curiously, and seemingly contradictorily, he takes five of the worst of the concrete pipes which were taken out of the trench whole, and five of the best salt-glazed stoneware pipes, and submits all to the test of weight saddled upon them, and found that the stoneware pipes bore 2,481 lb., and the concrete pipes 2,814 lb., showing the concrete pipes to be 13 per cent. stronger than the stoneware. The use of concrete for sewer pipes has, indeed, engaged Mr. Creeke's attention for some years, and it was after very considerable investigation as to the manufacture and testing in all its stages that he adopted it. For the purpose of decreasing the weight and cost of the pipes at Bournemouth, the thickness had been reduced to 1½ in., instead of keeping to the rule of 1-12th of the diameter, which would have been 2 in. for the pipes used there.

The makers of the pipes, Messrs. Henry Sharp, Jones, and Co., consulted Mr. Lemon, of Southampton, and Mr. Ellice-Clark, of Hove, as to the quality of their concrete pipes, and their suitability for sewerage purposes; and as to the cause of their failure at Bournemouth. The reports of both these engineers are much more satisfactory to us—and we doubt not will be so to all who are equally impartial in their view of the question—than are those of either Mr. Donaldson or Mr. Ponton. Their mode of testing the pipes—that is, by dead weight—is more in accordance with the actual conditions of a sewer than is that adopted by Mr. Donaldson—that is, by impact. Mr. Creeke also applied the dead weight test, and, except in the primary fault of the pipes being too thin, we cannot see that he is in any way in error.

Lastly, Mr. Reid makes a report to the manufacturers of the pipes, giving the results of his tests of the tensile and crushing strength of the material, together with some remarks on sand, &c.

Now, it is to be observed that all these concrete pipes failed by cracking longitudinally, and stoneware and fireclay pipes have sometimes failed in the same way; and we do not think that the cause of failure of these pipes at Bournemouth has been discovered.

ARCHITECTURAL MOSAIC.

I.—ANCIENT MOSAIC.

FORTY years ago Mosaic might have been reckoned among the lost arts so far as this country was concerned. It was treated as a subject of curious archaeological study, and considerable interest of a dilettanti kind was taken in it, but of English Mosaic there was absolutely none, nor had there been for centuries. The latest examples then known, dated back to the period of the great Medieval art revival about the time of Henry III., and even then, as we pointed out in a recent article, the art was a sickly kind of exotic, practised chiefly with imported materials and by foreign workmen. The modern revival of the art commenced in the year 1829, with an extensive and elaborate inlaid pavement by Mr. Blashfield, after designs furnished by H. S. Hope, Esq., at whose country seat, Deepdene, in Surrey, it was laid down. This pavement was formed of asphalt, coloured cement, and Venetian pisé work. In the same year, Mr. Singer, of Vauxhall, obtained a patent for a mode of forming tesserae by cutting with a wire apparatus pieces of the required form out of thin layers of clay, which were afterwards dried and baked in the usual way;

and in the next year (1840) Mr. Prosser, of Birmingham, discovered the now well-known "dry process," whereby a semi-vitrified substance of extraordinary hardness and density was produced by the pressure of powdered flint and clay between powerful steel dies. Prosser's process was at first applied to the manufacture of buttons by Messrs. Minton & Co.; but afterwards, at Mr. Blashfield's suggestion, to mosaic tesserae in various colours and forms. A new method of combining the tesserae into patterns, by placing them face downwards on a smooth surface and cementing the backs in sections of convenient size, was also introduced by Mr. Singer at the same time. The principal pavements executed about that period were in the hall of the Reform Club, in Pall Mall, and in the house of the Society of Arts, Adelphi. Mr. Herbert Minton took a very great interest in improving and extending the new manufacture, employing Mr. Owen Jones and Sir Matthew Digby Wyatt as designers, and since that time the art has improved to such an extent that modern work now fully equals, and even surpasses, that of the ancients. Modern mosaic, however, is so entirely a revival of the ancient that it can only be explained by reference to old examples and an account of the various processes in use at different epochs of its development.

In what country, or at what period, the art originated it is difficult to say. In the Egyptian Department of the British Museum there are some mosaic tesserae, and portions of the capital of a column with inlaid mosaic work, recently brought from a building at Tel-el-Yahoudeh, which is said to be of the time of Ramesses II., or, at all events, of far earlier date than the time of the Ptolemies, which has hitherto been said to have afforded the earliest specimens of Egyptian mosaic. There are also, in the Assyrian Department, examples of small mosaic work inlaid in ivory ornaments, from Nimroud, but they are mostly of Egyptian type. Hence we may infer that the art originated in Egypt, and was thence transmitted to the East. That it was known in ancient Persia we learn from the Book of Esther (chap. i. v. 6), which speaks of mosaic pavements in the palace of Ahasuerus, which, according to the marginal rendering, were of porphyry, marble, alabaster, and stone of blue colour—probably lapis lazuli—shaped specimens of which, that had been used for mosaic inlay, are to be seen among the Assyrian ornaments just referred to. The Greeks learned the art in the East, probably during their various Persian expeditions, and afterwards carried it to the highest pitch of excellence. In the days of Alexander, mosaic pavements of coloured marble were common throughout Greece, the floors being as elaborately decorated as the ceilings and walls, a fashion which gave rise to the story related by Claudius Galenus of Diogenes the Cynic, who walking across the pavement of a private house in Athens, whereon were depicted all the gods of Olympus, coolly turned round and expectorated in the face of the owner, with the left-handed compliment that it was the least noble spot he could find in the house for such a purpose. Mosaic is spoken of as *lithostrotion* by Hesiod and Sophocles, and *lithologemena* by Xenophon, the term *moussion*, whence the Latin *musivus*, and the modern *mosaic*, coming into use much later. Pliny mentions several Greek mosaic artists of great celebrity, particularly Sosos of Pergamos, but no original specimens of their work have survived to the present day. An ancient Roman copy of the celebrated work of Sosos, known as "Pliny's doves," is to be seen in the museum of the Capitol at Rome. This exquisite and well-known example fully bears out Pliny's high opinion. It represents four doves on the edge of a metal basin, one of which is stooping to drink, and the shadows, reflections in the

water, plumage, heads, and expressive eyes, are all depicted in minute mosaic work in the most beautiful and natural manner. The only other Greek mosaic now existing is a pavement discovered in 1763 at a villa near Pompeii, bearing the name of Dioscorides, of Samos, but it seems to have been only a copy of his design.

The art of mosaic was first introduced to Rome by Sylla about the year 80 B.C., when he returned home laden with the spoils of Greece and the East. It took the Roman fancy amazingly, and grew into surprising popularity, arriving at its highest perfection in the time of Hadrian, A.D. 117 to 138, and decayed at last only as the Roman empire itself decayed. During the reigns of the twelve Cæsars the workers in mosaic are said to have been among the most honoured artificers in the city of Rome, and no house or building of any importance was without its mosaic. Cicero describes the pavement of his own house as *lithostrotum*; Seneca said that he should indeed consider himself poor and sordid if the walls of his house were not adorned with mosaic, Julius Cæsar, according to Suetonius, carried a mosaic pavement with him, to adorn his tent, through all his campaigns and progresses, and wherever the Romans settled themselves, in Africa, Spain, France, Britain, or the East, they carried the art with them, employing materials found or manufactured in the respective countries, when the marbles, or fictile tesserae, of their own land were not attainable. The following is a brief description of the several kinds of Mosaic work in use among the ancient Romans:—

1. **OPUS TESSELLATUM**, or Tesselated work.—This was the most ancient kind, and was generally employed for pavements, very rarely, indeed, for walls. It consisted of small cubes of marble, seldom averaging more than $\frac{3}{4}$ of an inch square, each of which had to be sawn or worked by hand into the shape required by the pattern. This was nearly always geometrical in design, worked out with the Greek fret and many other ornamental combinations. The colours employed at first were probably chiefly black, white, and red; but blue and yellow were generally introduced subsequently to the invention of the *Opus Figlinum*. The best examples are at Pompeii, in the Sala of the Nuovo Braccio in the Vatican, and in the Baths of Caracalla, at Rome.

2. **OPUS SECTILE**, or Sectile work.—This was employed exclusively for pavements, and was composed of large thin slices of marble, not of little cubes. It depended for its effect, not upon the production of any particular design, but solely on the shape, colour, and vein of the marbles employed. Owing to the extreme costliness of the materials, it was very seldom employed, and no examples are known out of Italy. The most noble specimen of it now existing is the pavement of the Pantheon at Rome, built by Agrippa, 27 B.C. In this splendid pavement the slices of marble are very large, porphyry, giallo-antico, and pavonazetto being the principal marbles employed. They are arranged simply in round and square slabs alternately.

3. **OPUS FIGLINUM**, or Fictile work.—After the two former kinds had been for some time in use for pavements, a desire arose to employ mosaic as a decoration for the walls and curved surfaces of buildings. But for this purpose marble was often too costly, and did not possess sufficient variety of colour for the more elaborate designs, hence the necessity for an artificial, or fictile, material. This was a vitreous substance, composed of silex and alumina, but with a larger proportion of silex than is used in modern times, and was coloured by one or other of the metallic oxides. In the provinces of the Roman Empire ceramic tesserae were formed of the various clays of the neighbourhood, as for example, the fine

mosaic at Woodchester, the most elaborate discovered in this country, was constructed with tesserae made from clays now found in the neighbourhood of Gloucester and the Forest of Dean. The vitreous material was also gilded by covering a thin film of leaf gold, spread over the material, with a thin plate of transparent glass, or with a fusible mixture, and fixing the whole by heat. The advantages of fictile tesserae over marble were (1), Greater variety of colour; (2) Facility of working; (3) Cheapness; (4) Endurance of polish and brilliancy; and hence the *Opus Figlinum* soon almost superseded the former kinds of mosaic, and "glassy walls," *cum aureo superinducto*, overlaid with gold, became quite common, and were treated by the writers of the times as signs of too great luxury. Many examples of gilded mosaic have been found at Pompeii, perfectly well made, as pure in colouring, and as little obscured as when they were executed.

4. *OPUS VERMICULATUM*, or Curvilinear work, with its three subdivisions of Major, Medium, and Minor work, constituted the full development and perfection of the ancient mosaic. In this style mosaic took its place as one of the fine arts, and aimed at the direct imitation of all kinds of figures, ornaments and pictures, in their true shades, colours, and reflexes, and used both marbles and fictile tesserae, adding even jewels and precious stones when necessary, to heighten the effect. The *Major* work was used in large pavements, or ceilings, and presented mythological figures, gods, geni, &c., with various ornaments on a colossal scale. The cubes were of large size, not always square, but more often so than in the smaller styles, and the workmanship was coarse and rough. It was also employed in combination with finer work, for filling in the flat tints and large draperies. The surfaces, too, were usually left unpolished, being merely rubbed down. Most of the ancient mosaics found in this country are of this class, and the student should be cautioned that they by no means afford the best specimens of the ancient art; their workmanship being rough, and their manufactured tesserae comparatively soft. They owe their long endurance partly to the extreme solidity of their foundations, and to their having been buried out of the way of wear and injury for ages. The *Medium* work was much finer, and was used for subjects requiring greater delicacy and softness of treatment. The cubes were smaller, and the workmanship finer. It was sometimes used for pavements, but mostly for walls. Fine examples are found at Pompeii. The *Minor* work was the finest and most elaborate of mosaics. It was used for portable pictures and for personal ornaments. Many of the strips were less than 1-20th of an inch across, and even smaller. It was finished with most minute nicety, highly polished, and rivalled even painting itself.

Besides the above principal kinds of ancient mosaic there were others of a peculiar and subordinate kind, among which may be mentioned that called by Pliny, "the unswept floor." This was confined to the triclinium, or dining apartment, of dwellings, and represented the fragments of a feast which might have fallen down, and been left scattered on the ground in the utmost confusion. Pliny ascribes it to a Greek designer, in which case it is one of the few examples of bad taste produced by that nation. Another kind was the "*Opus incertum*," in which all kinds of marble were put together in an irregular shape, knitted into a mass with cement, laid upon the floor prepared to receive them, and reduced to a polished face by friction. They formed a handsome and durable pavement, resembling Venetian *pisé* and Italian *trazzo* floors, as used at the present day. Another most eccentric kind was the endeavour to apply mosaic to figures

in relief. A rude mezzo-relievo figure was formed, covered with plaster; and then portions of the surface were gradually chipped away, and their places filled with delicate tessellation. Very few specimens of this are to be met with.

The following were the ancient mechanical processes:—In laying mosaic pavements, great care was taken to form a solid foundation. The ground having been excavated to the necessary depth, a layer of large flint-stones, with but little cement, was first placed upon it, and above that a course of concrete, composed of smaller stones and lime, in proportion of 5 to 2, which was beaten and pressed down with great care until its thickness was reduced from about one foot to 9 inches. This process of beating was called "*rudratio*," and the stratum itself "*rudus*." Above the *rudus* was a third layer, called the "*nucleus*," which consisted of a kind of cement, composed of one part lime to three of crushed brick, pottery, &c. This was worked to a true face, and upon it was drawn the outline of the intended pattern. Then the tesserae were placed in their proper positions, and liquid cement poured over the whole, so as perfectly to fill up the interstices between the cubes. After the superfluous cement had been removed, all slight inequalities were reduced by friction with pieces of marble, and the whole was brought to one uniform surface.

For wall and vault decoration, after a smooth-keyed surface had been properly prepared, the tesserae were fixed with a cement called *marmoratum*, applied in small portions at a time, composed of slaked lime and powdered marble in the proportions of one to three, and blended with water and the white of eggs. This was intensely hard and very fine, but had the disadvantage of setting almost immediately after its application, which rendered it impossible to displace any of the work, even for alterations during its construction, without destroying the whole.

W. H. R.

AUCTIONEERS: THEIR DUTIES AND LIABILITIES.*

AUCTIONEERING, or the duties and liabilities of auctioneers, is scarcely a theme upon which we could expect much that was interesting said, but a work upon our table, by Mr. Robert Squibbs, auctioneer, just published by Messrs. Crosby Lockwood and Co., entirely and agreeably disappoints any such anticipations. Mr. Squibbs' aim, according to his preface, is "to produce a book of semi-legal character for auctioneers and their pupils," and to discuss the business relations of the auctioneer with the solicitor or his client, as well as his duties and liabilities to the purchaser. From a general perusal of the book we think the author has earned the gratitude of at least the pupil, if not of the young auctioneer, by divesting the usually dry forms and business routine of the profession of the dulness and repetition which might have been thought inseparable from them. Mr. Squibbs has thrown in here and there observations, incidents, and allusions which help to make the book very readable—though without detracting from its usefulness as a text-book. Quotations from, and references to, law reports and other legal publications are amply furnished, and we see an index of cases is prefixed that will be of much value to the student. Plunging into the work in *medias res*, we find some valuable advice is given, alike necessary to the auctioneer and to the purchaser or his agent. Thus it should be known that the power of the auctioneer to bind a purchaser does not extend beyond the auction, so if the auctioneer enters into a contract for sale of

unsold lots he should obtain the purchaser's or his agent's signature to the sale-book as evidence of the bargain; again Baron Park ruled in *Davis v. Danks*, that the auctioneer "has a special property, as bailee, in goods and chattels which are put into his possession for the purpose of sale, whether such are in his own rooms or in the house of another person." It may not be generally known also, that an auctioneer is liable for a misdescription of property. Thus, in *Parker v. Farcbrother*, the defendants, in their particulars, incorrectly described a house as having three floors, and another as in every respect similar to a number described. The houses were all bought by one man, who after the sale claimed compensation, though he lived next door. This was paid. The vendor sued the defendants, and the jury gave a verdict for the purchaser. In general, wrong particulars or mistakes are construed in favour of purchaser. A very interesting chapter is that on "Particulars of Sale," exposing in a humorous manner many of the tricks of auctioneers' catalogues, and the weaknesses of purchasers. Mr. Squibbs recommends the older forms of particulars of sale to auctioneers of the present day, who are apt to exercise their powers of description in a rather exaggerated manner. The author justly remarks, "Auctioneers may rush away into ecstasy over points of attraction, extent, and configuration, beautifully timbered miniature parks, and bijou residences, meandering streams, and Gothic facades, rich loamy or dry gravels, and everything else which may, in their eye, tend to attract the public in search of an investment, yet it must not be imagined that the beauty and admiration exist only in the eye of the auctioneer." In the old days, when a large estate was advertised, the auctioneer addressed himself to the wealthy landed proprietor or rich merchant, who could boast of splendid genealogies. Now all is changed; wealth is scattered, and there are many who, as the author tells us, are equally as susceptible as the auctioneer of attractive descriptions. Names go a long way with many people, and some euphonious title, "Orchardlea," or "Great Allington Manor," turns out to be a very unassuming, if not undignified, farmhouse. Mr. Squibbs recounts numerous instances of the perfidy of his craft: how many glancing down auctioneer's registers of properties find them out of the way, or inaccessible. The descriptive diction of the auctioneer as regards "residential freeholds," is often, we know, both inaccurate and contemptible, and tradition and the fancies of imaginative proprietors are often called upon to give an attractiveness to a property. "Society" and "Position" are often caught at in selecting a house near town; but, as the author says, "a noble town mansion" may mean many things, and may be considerably below the estimate formed of it in the eyes of the investor. Many amusing incidents enliven this chapter, but it may be sufficient to observe that these high-flown descriptions of houses comply with the taste of a certain section of the public, and that an auctioneer has to cater to this taste as much as the architect. The "ivy-mantled Gothic tower" or the ancestral hall of the Stuart age, even a Jacobean touch in the details, will redeem a multitude of vices in some minds. It is very necessary in particulars of sale, that the vendor discloses everything connected with the estate. In *Basecomb v. Beckwith*, an important issue was raised. The sale was subject to a condition that no public-house should be built or carried on upon the property. The defendant purchased on this condition certain lots coloured on plan, another excepted portion having been reserved by the vendor for the purpose of building a public-house. The Master of the Rolls, in commenting upon the evidence, thought the plaintiff could not compel the

* Auctioneers: Their Duties and Liabilities. By ROBERT SQUIBBS, Auctioneer. London: Crosby Lockwood and Co., Stationers' Hall-court.

defendant to execute the contract, if he insisted on retaining a certain plot free from any restrictive covenants. He also thought the conditions were not truthful, and that they ought to have fully disclosed everything where a specific performance of contract was required. In another chapter on "Conditions of Sale," the question as to whether the auctioneer or solicitor should draw these up is raised. No doubt, the auctioneer by their preparation undertakes grave duties and responsibilities, and it is very necessary he should limit the extent of his liabilities. The purchaser is, of course, entitled to a full investigation of the vendor's title, and the conditions of sale should afford him the fullest means of inquiry. The abstract of title of vendor is examined in the usual way by the purchaser's solicitor, who makes a list of "requisitions" or objections, and if any omission arises on his part the law holds him liable. If the auctioneer prepares conditions, the law would similarly hold him responsible for any omissions. Questions of light, drainage, right of way, or any other easements, are particularly necessary, and ought to be mentioned. On the subject of "Valuing," a few useful hints are given. The market value, though generally taken, is not always the real worth of a thing. In commonplace properties, the rental may be a test of value, but not always. Various circumstances have to be taken into the consideration of the valuer. The author truly says:—"It is not because a property is specially convenient or desirable to one individual that the sum which he has given is the correct market value. It does not follow that because one individual has given £50,000 for an estate, the annual value of which is £1,500, that that price is the market value." Many other inexplicable reasons exist for a difference of opinion. The valuation of buildings in towns is very uncertain, and the author thinks the "Metropolis Valuation Act, 1869," which provides a basis of value for the purpose of local taxation, may be taken as a useful guide. In speaking of freehold business premises subject to a rack-rent lease for a term of years, the author says, the valuer's safest course would be to estimate the value of the freehold in possession at, 1st, the actual rental, and 2nd, the improved estimated annual value, in each case deducting the value of the tenant's interest under the lease. The several kinds of leaseholds are next gone into, and the varying conditions affecting their value as investments are considered, though it is impossible to lay down any scale that will give the number of years' purchase of the ascertained annual value in all cases—this being a matter upon which the practical knowledge of the valuer and the circumstances of each case must be called to decide. The latter chapters of the book deal with the various other duties of auctioneer, such as collecting rents, effecting insurances, levying distress, arbitration, house agency, &c. Referring to ditches, the law relating to the same is stated. Thus it may bear reiteration, that the maker of a ditch cuts it out of his own land, throwing the soil upon his land, planting a hedge upon it, and therefore the edge of ditch is the legal boundary. "Lights" and "Fixtures" are discussed. Alterations or enlargements do not destroy the old lights, but alterations in position do. It may not be generally known, too, that a right to light may be lost by blocking up windows for one year. The necessity of a schedule of fixtures is urged. A copious index is furnished at the end of Mr. Squibbs' treatise, which will be hailed with satisfaction by all those entering upon the arduous and multifarious duties to which it is a capital introduction.

Mr. Thomas Jones, of New Swindon, has been appointed engineer of the Portland Convict Prison.

ARCHITECTURAL ASSOCIATION.

THE fortnightly meeting of the Association was held on Friday evening, the President, Mr. H. L. Florence in the chair; Messrs. P. D. R. Davies, E. J. Rope, A. Beesley, F. Moorhouse, R. Langton Cole, J. A. Marshall, and F. B. Bare were elected as members. Thanks were accorded to Mr. J. O. Scott for permitting the members to visit the new Greek church in Petersburgh-place, and to Messrs. Audsley and Joseph for similar courtesy as to the neighbouring synagogue, and it was announced that the next visit will take place on the 22nd inst. (to-morrow), when the new premises of the Society for Promoting Christian Knowledge, in Northumberland-avenue, will, by permission of Mr. John Gibson, be inspected. The President remarked upon the large proportion of the Institute prizes which had been carried off by members of the Association, the list including Mr. Millard, the winner of the Pugin travelling studentship, and Mr. F. Hemings, who was highly commended in the same competition; Mr. Sayer, Mr. Blagrove, and Mr. F. Pinches, the winners of the Tite, Grissell and Institute medals, and Mr. Vacher, who received honourable mention in the last-mentioned competition.

MEDIEVAL PARIS.

Mr. GEORGE H. BIRCH read a paper on this subject, illustrated by plans of the city and Notre Dame and other principal buildings. The history of Paris was sketched from the conquest of the city, then known as Lutetia, by Cæsar, onwards, the retrospect including a reference to the building by Constantine Chlorus (A.D. 292-306) of a palace, where he and his successor Julian the Apostate lived, and the remains of which are yet to be seen at the Palais des Thermes, in the Hôtel Chamy. References to the Bishops of Paris occur in the ecclesiastical chronicles of the fourth century, and at that period a church dedicated to Our Lady, was built on the island of the city. This church was sumptuously rebuilt by Childebert in the sixth century, and to the latter edifice probably belong the remains discovered in 1847, and preserved in the Palais des Thermes, consisting of portions of mosaic pavement and three columns of Aquitanian marble, one nearly complete with astragal and cap: Childebert also founded the Abbey of St. Victor, afterwards St. Germain des Prés. After Charibert's time Paris was abandoned as a capital in favour of more eastern cities till 888, when Eudes of the Caput line returned to the city. Paris gradually enlarged its borders, and made at length rapid progress under Philippe Auguste, when the faubourgs, suburbs which had sprung up around the chief roads and great abbeys, were for the first time inclosed. A wall bounded with towers and gates was commenced on the north side first, and completed in 1208, and afterwards the south side was taken in hand and completed about the end of Philippe's reign. In all views of Old Paris, the Tour de Nesle forms, said Mr. Birch, a very bold and striking object; the gate next to it is that called the Porte de Buci, then follow in order St. Germain, St. Michael, St. Jacques Papal gate, St. Marcel, St. Victor, and at the point of junction of the wall and the river was probably another tower, similar to that of Nesle; crossing the river end the island of St. Louis, the next is the Tour Barbeau, then follow the gates of St. Paul, Baudoyer, Barbette Braquelde, St. Martin, St. Denis, another not recorded, close to St. Eustache, then Montmartre, Coquillière St. Honoré, ending at the river with a large tower at a corresponding point to the Tour de Nesle, these two towers forming the defences of the bridge at each end. By this arrangement the great tower of the Louvre was excluded; it formed a strong fortification of its own, resembling our own Tower of London. Just as in England our Royal residence was at Westminster, and when abandoned by the sovereign the great courts of justice, over which the monarch was presumed to preside in person, remained; so in Paris, the Palais de Justice is now located where it had been from time immemorial in the ancient Palace of the Kings; La Sainte Chapelle, and a few outer walls, such as the Conciergerie, the Salle des Pas Perdus, the clock tower, and one or two other towers alone now remain of this palace. More fortunate than Westminster, it has preserved its beautiful chapel, while that of St. Stephen's was burnt in the last fire, leaving only the crypt; but Westminster has preserved its

grand hall and cloisters, while the walls only of the great hall of the French palace remain in the present Salle des Pas Perdus. Philippe Auguste, finding that the ancient palace on the island was no longer a convenient or salubrious abode, from the contiguity of houses, built and fortified the great tower of the Louvre (A.D. 1204). It possessed a great central keep, 144ft. in circumference by 96ft. high, and the usual collection of towers and walls forming outer and inner baileys or wards, and was used principally as a State prison. At this period three bridges spanned the Seine,—two ancient ones, Le Grand et le Petit Ponts, and the one built by Charles the Bald. Le Grand Pont, which afterwards received the name of Pont au Change, from the money-changers who fixed their quarters on it (for, like old London Bridge, these Paris ones were all covered with houses), was defended on the right bank by a fortress called the Grand Châlet, while a similar structure on the left bank protected the entrance to the Petit Pont. The Bridge of Notre Dame was first called Pont de la Planchette de Mibray, about which there is the following story. It had been rebuilt in 1413, but gave way 1499, and the Provost of the Merchants, corresponding to our Lord Mayor, was put in prison with the sheriffs for gross carelessness in not looking after the bridge, and taking proper precautions for public safety. Several skilled bridge builders and master-workmen from Tours, Orleans, Amboise, Lyons and other places were called in to give their advice, and to make a representation of a new bridge. But a foreigner, Brother John Jocundus, of Verona, obtained the first premium, and with the co-operation of two Frenchmen carried it out. The Pont St. Michel was the next antiquity. All these preceded the Pont Neuf, not commenced until 1578. The first wharf or quay was commenced in 1312, by order of Philippe le Bel. It extended from the convent of the Augustines to the Tour de Nesle. At the close of the thirteenth century, the churches, parochial and otherwise, but not including the cathedral, the abbeys, and other conventual churches, were thirty-six in number. In the Ile de Cité there were forty-three streets, 292 streets in the quarter of the right bank, seventy-six streets on the left bank, and eight others extra-mural; the number of inhabitants was estimated at 215,861, of whom 11,727 rateable and paying taxes lived on the right bank, 1,241 in the city, and 2,232 on the left bank. Paris was formerly only the seat of a bishop, and so continued from the time of St. Denis to A.D. 1622; it was one of the suffragan sees to the archbishopric of Sens, but Louis XIII. obtained of Pope Gregory XV. a bull erecting it into an archbishopric, which his successor very largely endowed, and created a dukedom and a peerage of France. The Cathedral Church of Our Lady at Paris would alone occupy a whole evening. Reference has before been made to the Basilica, erected by Childebert on the site of a more ancient fabric. Gregory, of Tours, distinctly says that there were two churches very close to one another, one situated on the southern portion of the present cathedral dedicated to St. Stephen the protomartyr, the other, a little to the north-east, to St. Mary. In A.D. 829, the Council of Paris assembled in the nave of that of St. Stephen, which was the larger and more sumptuous of the two. In the twelfth century, Etienne de Garlande, who died 1142, made considerable alterations and additions to the Church of the Blessed Virgin, and Suger, Abbot of St. Denis, adorned it with some magnificent stained glass, and it gradually eclipsed in splendour its more ancient neighbour, St. Stephen. Maurice de Sully had hardly attained to the episcopal dignity when he determined to unite these two cathedrals into one, and laid the foundation of the existing edifice in 1163, Pope Alexander III. himself assisting; in 1182 it was sufficiently advanced that the High Altar was consecrated; but at the death of Maurice in 1196 the choir was not completed, as in his will he directs 5,000 livres towards the lead roof to be paid. The works actively progressed under his successor, Eudes de Sully, 1197 to 1208, and in the latter year the great west front was commenced, under Peter of Nemours, in 1218. The last remains of the old basilica of St. Stephen were removed to make way for the south transept. Under Philippe Auguste the west end was completed as far as the base of the gallery connecting the two towers, and the magnificent appearance of this front influenced the rebuilding of the two transept fronts, which before were of

a sterner and less elaborate description. An inscription on the south transept attests that the work was undertaken by Jean de Chelles, in honour of the mother of Christ, 1257. The north transept and first chapels and the Porte Boriga, abutting on the transepts, followed, and the upper part of the towers and the intermediate gallery were completed very shortly afterwards. The end of the thirteenth and commencement of the fourteenth centuries saw a great change in the original grand and simple plan of the cathedral. Jean de Paris, archdeacon of Soissons, left a large sum for the addition of the lateral chapels of the nave between the buttresses. Those around the ambulatory of the apse date from the commencement of the fourteenth; and many other considerable changes, both internally and externally, which totally altered the original severe style. The present appearance of this truly grand cathedral, in spite of the rude storms of seven centuries, and those other storms, even more destructive, of human passion and violence, and robbery and wrong, is marvelously majestic. The stern and simple grandeur of its west front, incomplete as it may be without its crowning spires (and long may it remain so), still dominates over the Paris of to-day, as it did over the Paris of the Middle Ages, lifting itself up like a rock, and defying, as it were, the surging waves of tumult and strife which have been successively dashed against its base. The Abbey Church of St. Germain des Prés, both in point of size and antiquity, ranks next in importance to the cathedral. Situated at the extreme south-west of the city, it was once outside the walls, but the frequent depredations of the Normans caused it to be inclosed and fortified and defended by a moat. Childebert, on his return from a victorious campaign against the Visigoths, was moved by St. Germain, bishop of Paris, to found this abbey, to preserve the relics which he had wrested from them, and amongst these was the tunic of St. Vincent, and the day on which he died St. Germain dedicated it to the Holy Cross and St. Vincent. St. Germain dying very soon after, such miracles took place at his tomb in the oratory of St. Symphonian, in the crypt of the great church, that he soon became more in fashion than St. Vincent, and the church was ever afterwards called by his name. Nothing remains of the splendid buildings of the first home of the Benedictines in Paris, once surrounding the church, with the exception of a pile rebuilt during the Renaissance for the abbot's lodgings, but the church remains in a very perfect state, although shorn of two of its spires. The plan is that of a large transeptal church with apse, ambulatory, and radiating chapels; towers in the very unusual position of flanking the choir in the angle formed by the transept, and a large western tower and spire. It served as a place of sepulture for all the kings and queens of the Merovingian dynasty until Dagobert founded and built the abbey of St. Denis, which became in after years the Westminster Abbey of France. The refectory, built by the same architect as the Sainte Chapelle, Pierre de Montereil, was looked upon as the most magnificent anywhere; it was vaulted, 115ft. long, 32ft. wide, and 47ft. 7in. to the vault. Close adjoining to this was the chapel of Our Lady, only rivalled by the Sainte Chapelle. Internally, the nave of the abbey church consists of five bays, then the transepts of only two bays in depth, a choir of four bays, and an apse with five bays and apsidal chapels of very small projection. Unfortunately for the architecture, it has been painted all over, utterly destroying all interest in it, although imparting another from the excellence of the painting by the late Hippolyte Flandrin. The date of the work in the nave is eleventh century, that of the choir slightly later, as the Pointed arch, in conjunction with the circular, first makes its appearance. Pope Alexander III. dedicated the church in 1163, and there is a certain similarity in the magnificently bold caps of the columns in the choir to those in the nave at Notre Dame. I am sorry to add that many of the caps of the nave are modern; the originals are in the Museum at the Hôtel Clugny, but as they have all been more or less gilded and painted, it is now very difficult to discover which are ancient and which are modern. Turned into a manufactory of saltpetre during the demerit period of the Revolution, it was pretty nearly utterly destroyed, and would have shared the fate of its superb abbey buildings. Many of the royal tombs which were first transported to

the Museum of the Little Augustines were afterwards removed to St. Denis. One or two points are worth special attention. The first is the very marked deviation of the choir from the axis of the nave; secondly, the very rare ancient marbles worked up in the columns of the triforium stage, evidently the remains of Childebert's basilica; and, lastly, it was in the prison of this abbey that those horrible massacres first commenced, giving rise to that significant term, *Septembriseurs*, applied by those demons of the Revolution to the horrible work of that month.

(To be continued.)

HOUSEHOLD SANITARY ARRANGEMENTS.—V.

PROFESSOR CORFIELD'S fifth Cantor lecture, delivered at the Society of Arts' last Monday evening, was principally devoted to the consideration of sewerage arrangements. Under the term "sewers" he included all pipes and conduits used for the conveyance of refuse by gravitation, whether laid in houses or streets. In some country places where dry systems of disposal are adopted, the waste liquids are got rid of by passing them into agricultural drains, and these being porous and loosely jointed, too often allow the fluids to escape at the first few joints, while the fatty matters cling to the leaks, and gradually choke the pipe. Some mode of flushing is, therefore, essential, and to meet this want Mr. Rogers Field has devised a self-acting flushing tank, the action of which was illustrated by diagrams, working model in glass, and a specimen. It is an earthenware tank, having at the opening in top by which the water is received a loose iron grating, which again fits into a siphon-shaped bend of tubing. There is also an overflow-pipe, but this, of course, only removes the water above its outlet level as received. The peculiarity of this tank is that it also contains at one end a large siphon, which starting a little above the bottom passes through the side near the top of tank, this long leg ending at a lower level above a small weir, communicating by channel with drain. By an experiment performed with a large glass model lighted from behind, it was shown that the tank can be filled to its utmost capacity, when the slightest addition to the contents seals the siphon by the aid of the water in the weir, and the tank is quickly emptied to the level of the short leg of the siphon. The sediment is retained in the tank, and can be removed by other means, while the sudden discharge of water is sufficient to flush a drain. Proceeding to his chief subject, the lecturer remarked that in towns the main sewers in streets are usually built of brickwork and egg-shaped in cross section, that form affording the best scour and least friction, and being easy to construct. House sewers are often of stoneware, and these are circular in section. Speaking generally, all sewers below 18in. diameter ought to be of glazed stoneware; above that size the greater cheapness of bricks and the ease of construction made brickwork the most practicable material. In these cases the bricks should be of the very hardest kind, and should be set in cement. It is a good plan to use invert blocks of stoneware for brick sewers. Some made by Messrs. Stiff and Sons were exhibited, a noticeable variety being that in which a gridded rest is placed beneath the sewer, impervious vertically so as to prevent leakage, but pierced longitudinally to facilitate subsoil drainage. Stoneware mains would be used to a much greater extent in small streets and towns were it not for the mistake so often made in estimating the size required; sewers are almost invariably too large, a survival of the old practice of planning them capacious enough for a man to enter and cleanse them. That cleansing can be effected by flushing, provided the sewer be nearly or quite filled with water, under high pressure, and the flow is sudden; management is more requisite than mere quantity of water. Given sufficient size in a sewer, all beyond is an absolute disadvantage, as the sewage flows in a shallower stream, more foul air is allowed to accumulate, it is more difficult to flush it, and it is increasingly expensive in construction. In laying sewers provision should always be made for making new connections without cutting into pipes; junctions should be laid in a line with the flow of streams, as otherwise the larger channel becomes blocked with sediment at the intersection. Pipe sewers are usually jointed

together by sockets luted with cement. Where there is no risk of settlement this is the best arrangement, as it allows no leakage, and the stiff joint necessitates keeping the line of sewer straight. Where there is a probability of settlement or pressure the makeshift plan is adopted of luting the joint with clay and adding an external ring of cement. Simple clay joints are a mistake; frequently, as the lecturer had had frequent opportunities of seeing in London houses, the clay is washed out by the percolation of fluid, and the sewer becomes blocked up by sediment collected around the leak. Another kind of joint is Stanford's patent, in which the one tube fits into the other by a conical end covered with some elastic composition, which is greased before insertion. Where the pipes are straight this makes a water-tight joint, but great care must be taken during laying to insure that no chipped caps are passed. In private property subsequent connections may be provided for with the ordinary socket-pipes by inserting junctions at points that will suggest themselves. With street mains more ample provision should be made, both for connections and inspections. This can be done by using Jennings' spigots, which, by a series of loose half-pockets on the upper side, allow of the sewer (which has no sockets) being opened at any point without cutting the pipes. With ordinary socket pipes, Doulton & Co.'s operculum or lidded pipes may be used with advantage, in these about 1-3rd of the upper part of pipe is so nearly loose that it can be easily detached by a tap from a chisel. Yet another contrivance for obtaining ready access to sewers without having to cut into them, is the "capped" arrangement; in this method half-a-circle is cut out of each pipe as it is made, so that when two pipes come together a round hole is left at the top. After the sewers have been laid and examined these holes are closed by means of lids made for the purpose, which may be removed at any time for new connections to be made. These pipes are made by Jones and Co., of Bournemouth. Main sewers require ventilation, and this is most perfectly secured by openings at the street level. If such ventilators are a nuisance, it is evident that foul air accumulates in the sewer which but for this would pass into the houses; the remedy is not to stop up the ventilator, but to make another or two to allow of freer passage of fresh air. The ventilation of sewers is never perfect till it is constant, and sufficient to prevent all objectionable smells, and all complicated plans for effecting this have proved miserable failures. More than 30 years since it was proposed to connect all sewers with furnaces so as to draw out and consume the foul vapours. The scheme was tried at Battersea, and acted with a vengeance at times, the air being occasionally drawn through the houses, breaking the water seals of the traps, while at intervals the operation was too sluggish to have any good effect. One day some coal gas leaked from the gas to the sewer mains, and the works at Battersea were wrecked. Yet the same idea has been put forward within the past four years as a novel and practicable idea, notwithstanding the literal explosion of the theory in 1844. The ventilation of house sewers should be effected as far as possible from the dwelling. Where it must be near the house the ventilating pipe should be carried well above the ridge of the roof, so that whatever quarter the wind blows from the foul air must be driven away from the house. Private sewers should never be of brick, for not only is there great danger of leakage both of fluids and gaseous contents, but they can be eaten through by rats, who to their ravages in the larder add the danger of bringing sewage matter on their coats and feet, while their run form convenient exits for sewer-gas. It is preferable to keep all sewers to the backs of the houses, where the sculleries and offices are situated; but as our main sewers are generally laid through the front streets, it is in most old towns unavoidable that the house sewers shall pass under the premises from back to front. They ought, therefore, to be of glazed stoneware, and to have a fall of at least 1 in 48. In all but large mansions 6in. was ample diameter for house sewers, with 4in. branches. Connection with the main sewer is usually made through a galvanised iron flap, hung so as to remain closed except when sewage passes. This flap does not keep sewer air out, and only prevents the entrance of rats when it is not propped open by a slight obstruction. In addition to this, some form of water trap should be used to check the entry of gas. Formerly, a dipstone was used for this purpose; a rectangular piece

was made beneath the sewer, and into this a stone hung vertically, so as to maintain a constant depth of water. It was, in fact, a mitigated cesspool; deposits were retained especially in the corners, and the nuisance was greater than if no trap had been used. An improvement was to slant the depending stone to an angle corresponding with the flow of sewage, and to obliterate the angles of the recess, and a further development made the fall sudden on the inward side and gradual at the exit. Every trap is in reality a cesspool, and the aim should be to obstruct the flow as little as possible, while securing such a bend filled with water as to check the upward passage of gas. If our main sewers were properly ventilated, he doubted if any kind of trap would be of use, but until public opinion is sufficiently advanced, their imperfect protection must be availed of. The simplest form is that of a shallow siphon, of which several varieties were shown, stoneware being recommended as the best material. Even these get stopped up occasionally, and a vertical pipe should therefore be taken from the top of trap to ground level to allow of flushing and inspection. Following upon these improvements, it was found advisable to permit air under certain precautions to have access to the private sewer, if between the water-trap and the house. Whether the gas is generated in the private or main sewer it is an advantage that it should escape into open air rather than into house, and if air passed inwards this was also a benefit. This air connection can be obtained in several ways. In Weaver's trap a pipe is built up from the trap to the front area of house, and is here covered by open grating. Buchanan's arrangement resembles this, only the fall of house sewer is more vertical. In Potts's Edinburgh chambered trap, there is a large open channel, communicating with external air by long inlet. This method is exceedingly useful where sewers are being laid for first time, but the length of fall required is considerable. Professor Fleming Jenkin advocates the use of two siphons, one behind the other, so that if the water seal of the first should be destroyed, the second will remain intact, but Dr. Corfield regarded this as a needless complication. If two were better than one, why not employ three, or, indeed, a whole series of siphons. A rather more expensive disconnection than those mentioned, is one recently introduced; it consists of a man-hole placed over a chamber, with an open channel in the section of sewers running beneath it. The man-hole is entered by a locked galvanised-iron door with open gratings, and a pipe passes from the chamber to roof of house, with gratings at intervals. Dr. Corfield expressed his belief that in the end this would be found the best plan for disconnection, ventilation, and inspection. He had never known a single instance in which this system of manhole and pipe disconnection and ventilation had proved a nuisance, and under no circumstances could foul air accumulate in such a house sewer. In any method of ventilation it is desirable that the outlet should be above the roof-level rather than in the area. Cows may, by some, be thought ornaments, but for practical purposes are better omitted, and a couple of wires or a grating placed over the head of pipes. One accidental advantage of cowl is, that if they are added, people suffer a pipe to be carried higher than otherwise. It was necessary that there should be a connection with sewer from lowest part of basement, to provide for the removal of water used for cleansing the floors, and against accidents, such as floodings from burst water-pipes or boilers. This receptacle and its pipe should be well ventilated, and only discharged into sewer after passing through an open space, even if the channel were at the bottom of a grated shaft sunk in the area. The entire disconnection of this basement drain was of great importance. Dr. Corfield announced that, in his closing lecture, to be delivered next Monday, he should treat of water-closets, sinks, and baths, and the arrangement of their pipes and traps.

RAILROADS AND STEEP INCLINES.

IN a paper on "Experiences of Early Engineering Operations on Railroads," read by Mr. W. Milner Roberts, C.E., before the American Society, and reported in the last number of their *Transactions*, the author recounts his experience of steep inclines in connection with the Pennsylvania railroads. Railway enterprise

had just commenced in England, and Mr. Roberts was employed as a young assistant of Mr. Canvass White, then a leading engineer. The first American coal and passenger railroad was that from the summit of the Broad Top Mountain; the inclined plane had an elevation of about 200ft., its length being about three or four times its height. It had a double track passing-place at the middle, but single at the ends, and was worked by gravity. The loaded car in descending turned a large drum at the head of the plane around which the rope was wound which pulled up the empty car. Another plane, on an improved principle worked by water-power, was constructed by Mr. White in 1827. The motive power, we understand, was by a water-wheel geared into movable bars or racks along the entire length of inclined plane. The writer details his experience in the construction of several planes on the western and eastern slopes of the Allegheny Mountain. These planes varied from 8 to 10½ per cent.; the longest being 3,116ft., including a short curve at the top, and a curve 200ft. long at the bottom; its rise was 308ft., the straight part an inclination of 10½ ft. per 100 or an angle of 5° 51'. The plan of working adopted was a double track, and an endless rope worked by a stationary engine at the head. We may also mention that in 1824 a canal through the Allegheny Mountain and a tunnel 4 miles in length was proposed—the last was ridiculed; but canals were looked upon with more favour at that time, and most of them were begun in 1826. The author says a railroad over the mountain was authorised in 1829, with inclined planes between the terminal points of the canals—Hollidaysburg on the eastern and Johnstown on the western side. Eleven inclined planes were proposed, and ultimately five on each side were adopted, all straight; the maximum inclination was 10½ ft. in 100ft. There was an impression at this time that locomotives could do very little work on grades above 30ft. per mile, and this gradient was the maximum adopted by Major Wilson, who planned the first State railroad between Philadelphia and Columbia, and this necessitated two inclined planes called the "Schuylkill" and the Columbia, the former being over a mile in length with a rise of 187ft. In 1847 the Legislature appointed the author to survey and report upon a route avoiding the Schuylkill Incline. The Allegheny Portage Railway was opened in 1834. Any persons could put cars on the track and haul them with their own horses from either end to the foot of the first plane and on the intermediate level; the State only transporting the cars up and down the inclines by means of engines. Into the details of the machinery for working the planes, we refer to the author's paper; suffice to say, there was an endless rope 3½ in. diameter passing round a horizontal double-grooved wheel at the head of plane and thence supported on numerous sheaves, set in the middle of the tracks to the foot and around a movable grooved wheel below foot of plane. The writer records incidentally the boring of a well 800ft. deep from the head of one of the planes, which turned out absolutely dry, the rock bored being compact slate. Subsequently the inclined planes of the Allegheny Portage Railroad were abandoned for a graded railroad. The author says, "few travellers who view the beautiful scenery of this part of the Allegheny Mountains are aware that there are two important railroads, the Pennsylvania and the New State Railroad, now dead almost in sight at the summit of the mountain." This graded road had gradients of 75ft. per mile and 52ft. per mile. The writer next describes the construction of the Dom Pedro Segunda Railway, Brazil, across the "Sierra" back of Rio Janeiro, a very difficult work, as the summit of the mountain to be surmounted was about 500ft. above the grade of railway at the eastern end of the *Tunnel Grande*. The length of the track, which was temporary, was 5 miles, the maximum grades being 238ft. per mile, with curves of only 230ft. radii. At this time the people declared they would "never ride under the Sierra through the Big Tunnel," and they long preferred the more perilous journey round the summit, the speed of the trains being limited to 5 or 6 miles an hour. The tunnel was pierced through granite which, singular to say, was not compact in the centre, but was found very wet, and of partly decomposed granite subject to heavy caving and requiring stone arches and walls. The paper of Mr. Roberts is interesting as showing the early methods of traction along steep gradients, while experience has given proof that

the ordinary frictional adhesion of locomotives is ample for almost every practicable degree of acclivity.

BRICK ARCHES FOR LARGE SEWERS.

IN a paper by Mr. R. Hering, C.E., read before the American Society of Civil Engineers, some useful observations are made upon the conditions of stability of arches with long axes. In the city of Philadelphia several miles of large brick sewers are constructed as large as 20ft. diameter, and some of these have failed by total collapse or by flattening at the crown and spreading at the springing. Circular rings of a thickness determined by formula appear to have been employed, the spandrels being filled with rubble, and having abutments. The author first describes the failure of a large sewer—the Mill Creek—20ft. diameter at the spring, built of two concentric rings of brick with rubble masonry abutments, battered outwards at the sides, and straight below the invert which is segmental. The section resembles that of a tunnel of ordinary construction. The mortar is described as poor and scanty, and the drawing given illustrates the line of pressure graphically worked out. This line is not confined to the middle third of the joint area, but is shown to intersect the joints of rupture at the crown and haunches of the original sectional form at 1-10th of the thickness of section, locating the neutral axis at 3-10ths, which leaves 7-10ths of section under tensile strain, and 3-10ths under compression. The effect of this as well known is because the joints at crown in the intrados, and those of the haunches in the extrados, to open, as the neutral axis in this instance passes within the section. The sewer was found to have been crippled accordingly. In short, the author shows, by calculation, that the strain in the arch amounted to 429lb., whereas, according to Trautwine, cracking and splitting of brickwork occurs at about 400lb. All the effects of chipping at the joints expected were found to have occurred in this case, thus proving that the theory and actual failure agreed. The arch was found to have changed its form by sinking at the crown throughout its length. Another example is illustrated a sewer with an elliptical arch, 18ft. 6in. in diameter, varying from 18in. thickness at crown to 3ft. at springing, having changed its form in a similar manner, though the materials were good. The author next shows a section of a differently designed sewer arch, based on the method of graphical statics, in which the following points were observed:—1. "That at no point should the material be subjected to more than a safe fraction of its ultimate crushing strain." The author assumes the safe resistance of brickwork at 80lb. per square inch, and proposes a convenient formula, as follows:—

$$\text{Least thickness of arch in ins.} = \left\{ \begin{array}{l} \text{Pressure at joint of rupture} \\ \text{in lbs. per foot lineal} \\ 480 \end{array} \right.$$

2. The bed joints of the bricks should be as nearly as possible at right angles to the direction of the line of support. 3. The line of pressure must be situated in the kernel or middle third of the arch to prevent any tendency of rotating. It must also intersect foundation at a point sufficiently far from edge to be safely resisted. Another point, we may mention, is that the brickwork is to be bonded so that the line of pressure will pass through the middle of the headers as much as possible to prevent separation of the rings. A section of a sewer is shown, the result of attention to these points. The arch is struck from 3 centres, the crown at 8ft. radius and the lower arcs of sides at 17ft. 8in. radius; the arch is thickened as it descends to the rubble abutment, and the stones of the latter are placed so that the line of pressure cuts them at right angles to their bed joints. We are informed the arch has stood well for two years, and there is no sign of cracking, change of form, or chipping of bricks. Mr. Hering's arch is certainly based on common-sense principles, and the wonder to us is how the other form could ever have been applied to so large a sewer.

The following building grants were made at the last meeting of the Gloucester and Bristol Diocesan Association:—Churches: Elmora, £100; St. George's, Gloucestershire, £150; Moreton Valence, £50; St. James, Gloucester, £150; Taynton (Mission room), £30; Sutton-under-Brilles (additional), £50.—Schools: St. Luke's, Barton-hill, £50.—Glebehouses: Chedworth, £50; Coaley, £50.

MOVABLE BRIDGES.

At the meeting of the Institution of Civil Engineers, on Tuesday, the paper read was on "Movable Bridges," by Mr. James Price, M. Inst. C.E.

The term "movable" was used as being more general in its application than any other. Such bridges mostly occurred where delay of traffic was to be avoided. Hence rapidity of movement and minimum of repairs should be sought. There should be no unnecessary weight; for this reason steel was preferred to iron as a material, saving 25 per cent. of the weight of the parts strained. Movable bridges were divided thus:—1st, bascules; 2nd, swings; 3rd, traversing; 4th, lifts; 5th, pontoons.

1st. Bascules were illustrated by the railway bridge over the Ouse at Selby, erected in 1839. The largest of this kind had been opened at Copenhagen in 1867. Overhead beam bascules were much used in Holland, the beams being usually of timber. The author had erected a large single flap bascule over the Shannon, to carry a railway; the floor was open to let the wind through when the flap was raised; it acted well. 2nd. Swing bridges formed the most important class, and all large structures in Europe and in America belonged to this type. Double passages were preferred, as obviating heavy counterpoise and wind stress; instances of both occurred in the South Bridge, Hull. Swing bridges were classified thus:—Those that turned on rollers only; those that turned on rollers and a centre pivot; those swung entirely on centre pivots; those lifted on a water centre and tilted; those relieved by hydraulic pressure acting upwards at the centre; and floating swings. Unlimited hydraulic power available for turning was not conducive to obtaining light and well designed structures. The earliest swing bridges were of timber; then cast iron was employed, and now they were universally of wrought iron. The Brest Bridge, having two leaves, spans the largest passage crossed by any movable bridge; it turned on rollers. To the same class belonged also the railway bridge over the river Ouse at Goole, which was almost the largest railway movable bridge; it crossed two passages of 100-feet span each. There were several bridges of this kind at Birkenhead. The Duke Street bridge rested on rollers 5 feet in diameter; it was not balanced over the centre, and was difficult to open. Athlone Bridge, over the Shannon, had rollers only 8 inches in diameter; it worked badly. The great majority of swings turned on rollers and a centre pivot, including all the large American bridges; the most notable was the Raritan Bridge, a double swing, with two passages of 216 feet in width each. This bridge, which had been erected by the Keystone Bridge Company of Philadelphia, was peculiar for being lifted entirely off its abutment supports, thus needing no wedging up. To this class belonged also the tilting bridges generally adopted in France, at Dunkerque, Gravelines, Havre, Cette, and Tonlon. The same type had likewise been adopted in North Germany. The principle might be described thus:—The whole bridge being slightly out of balance, each leaf or the heavy end was set up by various methods; and when the abutment support was withdrawn, it dropped on two or more wheels, the main weight, however, being carried by the centre pivot. A bridge of peculiar construction had been erected at Grimsby to carry the Manchester, Sheffield, and Lincolnshire Railway; it had no tail-end or counterpoise; it was anchored at the pivot, and bore with a pressure of 122 tons on a pair of wheels near the edge of the passage. The Dutch type belonged to those turned entirely on centre pivots. They were to be seen at Rotterdam and Velsen, on the North Sea Canal. The girders were under the roadway; and the point of support was brought above the centre of gravity by means of a long cone passing up between the girders. In those lifted on a water centre and tilted, the leaves were slightly out of balance. When the centre was raised by hydraulic pressure, the bridge tilted so as to bear on wheels. In some cases, as at Leith and at the Albert Dock, Hull, the tail-end was heavier, and dropped with its wheels on to a tramplate. Or, as at Marseilles, Millwall, Stobeross (Glasgow), &c., the tail end was lighter, and rose in tilting till its wheels bore against the underside of an inverted tramplate fixed round its sweep. The dimensions and arrangements of the Leith and Marseilles bridges, which were

constructed in the same year (1874), were compared. Swing bridges, relieved at the centre by hydraulic pressure, were represented by the Tyne Bridge, which was the largest and most perfect in this country, having two passages of 110 feet each. Floating swings, as constructed by the author in Dublin, were used, one to carry a double carriage road, and the other a single line of railway; the latter acting also as a turntable for waggons, so as to shoot them across the dock entrance. The principle was to support nearly all the weight on a submerged buoy, which turned on a centre pivot on the bottom. These bridges were effective, and suitable for places where the foundation was bad. Traversing bridges required much power. The larger ones were represented by the bridge at Swansea, over the River Tawe, in which the heavy end was across the passage. In swing bridges that turned on rollers, by withdrawing the supports from the long end, the tail end rose till the wheels came level with an upper traversing rail, upon which the bridge was rolled back. In the case of the Millwall Dock, the centre was raised by hydraulic power, and the light end, which crossed the passage, was held down by horns, that prevented it rising; hence the heavy end rose to the proper level to be rolled back. There were many other forms of traversing bridges, the best for a railway and manual power being at the Dovey Viaduct. Mr. Kinnip's submerged caisson was also a traversing bridge, the wheels taking the portion of weight not buoyed up, running on rails laid in the bottom; it bore the same relation to other traversing bridges as floating swings did to other types. The balancing of both swing and traversing bridges should be as nearly as possible over the centre, otherwise, particularly in the former, motion was difficult. The proportional lengths of tail ends of swings varied. In the Marseilles Bridge the tail was to the passage arm as 0.62 to 1; in the Brest Bridge, as 0.50 to 1; and, in the South Bridge, Hull, as 0.40 to 1. These represented extreme and mean cases. If possible, the counterpoise should form some useful part of the bridge, such as cross girders and flooring combined, in the form of a solid cast-iron floor. The modes of setting up the ends were various, consisting of wedges, inclined planes, toggles, weigh shafts, eccentrics, hydraulic lifts, screws, &c. The Phoenixville Bridge Company had a self-adjusting joint of the rails, something similar being used at Keadby Bridge. At Marseilles, there was a bridge which was a combined bascule and swing. The first motion of the centre ran lifted it off the bearings only for being swung; but it could be further lifted till a part of the bridge turned round a horizontal axis; and it allowed barges to pass without being swung, thus saving much time. Lift bridges, which rose bodily, and allowed a passage for canal-boats, were not common. One had been erected over the Surrey Canal, and another by the author, which worked well and easily. The author had charge for many years of an ingenious pontoon bridge, erected by Mr. Robert Mallet, M. Inst. C.E., which worked most satisfactorily; it was now done away with, a portion of the canal which it crossed having been filled.

COMPETITIONS.

NEWTON ABBOTT.—For plans for the erection of a coffee-tavern in Market-street, Newton Abbott, the directors of a limited company recently offered premiums of £20 for the best, and £5 for that placed second. Some twenty designs were sent in and the directors have selected those by Mr. Jones, architect, of London. It seems doubtful whether the scheme will be carried out, as some of the shareholders incline to purchasing and altering an old house instead of building.

PENDLETON.—A competition has been arranged for the rebuilding of Brunswick Wesleyan Chapel, Pendleton, the cost of which must not exceed £8,500. Designs have been sent in, under mottoes, by four architects invited to compete, and they are now on view in the present chapel. The trustees have not yet selected any design.

SPALDING.—About sixty designs were sent in for the new Johnson Hospital, proposed to be erected in Spring-gardens, near St. Peter's Church. Of these twenty-five have been marked by the trustees as selected for further consideration, these being by architects in London, Leeds, Leicester, East. Dereham, Warwick, Peterborough, Stamford, and Derby.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

ANCIENT GRAVES IN ROSS-SHIRE.—At a meeting of the Society of Antiquaries of Scotland held in Edinburgh on Tuesday week, Mr. Jolly read a paper describing the ancient graves recently discovered at Dahmore, in Ross-shire. The first group of ten graves was found above Dahmore distillery. They consisted of cists formed of flat stones of different sizes resting on the ground and covered on the top with one or more flat stones of larger size. This group appeared to have been enclosed within a stone wall, the base of which could be traced on three sides covering a space of 108ft. by 66ft., the shorter walls running north and south. In the most westerly grave of the group—which was about 2ft. 6in. by 1ft. 8in. and 1ft. broad—there was a skeleton in the contracted position, finely worked flint-knife, a necklace of 50 beads of shale, and a "bracer" a stone implement supposed to have been used to protect the left wrist from the recoil of the bowstring. The other graves all contained burnt bones, accompanied in some cases by urns, one of which was of very unusual type. The bones were mostly human, but in some cases mixed with those of animals. In one grave a fragment of a small oval bronze blade with a tang was found. The second group of graves was about 200yds. from the former. The graves were eight in number; of these two contained burnt bones, three had remains of unburnt bodies accompanied by urns, and in the other three no remains were discovered. The paper was illustrated by plans and drawings by Mr. Alexander Ross, architect, F.S.A. Scot., and Mr. Maclean, of Easter Ross.

SCHOOLS OF ART.

NATIONAL ART TRAINING SCHOOL.—The medals and other prizes won by students of the South Kensington Schools in the local and national competition of 1878 were distributed on Monday, Mr. Poynter, R.A., Director of the Art School, said that the prize-winners were students of the two schools at South Kensington—one for male and one for female students—the schools being in competition with each other, and with all those of the United Kingdom. Explaining that the competition among the students in training and national scholars was, on account of the exceptional advantages they enjoyed, separate from that of the general students, he enumerated the higher distinctions—one silver medal, two bronze medals, and 13 Queen's prizes of books—won in the national competition, besides 66 prizes of books won in the local prize section—in all, 82 prizes. The students in training and national scholars competing for honorary distinctions obtained 3 gold medals, 11 silver medals, 21 bronze medals, and 20 Queen's prizes of books. In the competition for prizes open to all students in the National Art Training School the awards included 10 silver medals and 21 Queen's prizes of books—a grand total of 171 prizes. The number of individual students attending the schools during the year had been 849, of whom 384 were male and 465 female students. In the 3rd grade or highest examination 29 of their students had obtained the teachers' certificate. The fees paid amounted to £3,832, of which sum £316 came from evening students and the balance from the day students. Mr. G. Morton had gained the gold medal for a life study. The students had not gained the gold medal for studies of the antique, and they had been beaten by the Edinburgh School, and also by the Bloomsbury School of Art—a school composed entirely of ladies. The general standard in the South Kensington Schools was, however, now considerably above that of three or four years ago. In the modelling class they had carried off all the prizes worth anything.

SOUTH LONDON.—The prizes awarded by the Science and Art Department to the students of the Southwark, Nine Elms, Greenwich, Woolwich, and Stepney Science Classes were distributed at St. Olave's Grammar School, Southwark, on Friday week, by Professor J. E. Thorold Rogers, who delivered an earnest address to the students, impressing upon them the value of self-culture. In closing the proceedings, Mr. Parton Parry, under whose direction the classes were held, said it was an undoubted fact that the Continental workman was beating the Englishman out of the market. He deplored the want in this country of a cheap and simple system of patent laws.

ST. MARY'S CHURCH, SHIPTON.—CHURCH OF SS. PETER AND PAUL, WATLINGTON.—HOUSE AT HAMPSHEAD.—PREMISES, CORNERS OF NEW BOND-STREET AND CONDUIT-STREET.—ENTRANCE GATEWAY TO SOMERSET HOUSE.

OUR LITHOGRAPHIC ILLUSTRATIONS.

SHIPTON BELLINGER CHURCH, HANTS.

At the end of the last century the fabric of this church having become dilapidated, it was treated in a very ruthless manner; the walls of the nave were lowered about 3ft., cutting off one-half of the tracery of the windows and the rood screen and many ancient features destroyed. Thus it was left until last year, when the chancel being in danger of falling, the then vicar, the Rev. W. C. Baker, inaugurated a movement for its repair and renovation. Sir John Kelt, Bart., the patron of the living, and others having provided the necessary funds, the work of restoration is now being carried on under the direction of Mr. Withers. The chancel is almost wholly rebuilt, the nave walls raised to their original height, the windows and stone rood-screen restored from fragments found in the walls, and the whole building newly roofed and refitted. Three fine old bells remain, and will be rehung. Painted glass by Mr. Daniel Bell fill the east and west windows, being gifts of two former vicars respectively. The church is dedicated to St. Peter, and the annual village feast is still held on the 12th July, the morrow of St. Peter, old style. The cost of the work will be about £1,400, and the builder is Mr. Sturgess, of West Cholderton.

WATLINGTON CHURCH, NORFOLK.

This fine fourteenth-century church lies midway between Lynn and Downham, and among so many dilapidated buildings it stands almost unique in fine preservation. Less than usual has been done to the fabric in the shape of alteration. The ancient sacristy, easily traceable, is gone, and its place filled by a mortuary; the aisle roofs are modern of the worst type; the porch has been badly rebuilt, and, with the exception of a few ancient seats, font, pulpit, &c., the interior fittings are modern. The chancel roof is original, whilst the nave, roof, and clerestory date from the sixteenth century. The beautiful and varied tracery and proportions of the windows, piers, and arches, and their excellent preservation are worthy of note, being constructed of Barnack and Clipsham stone. In its repair and refitting, under the direction of Mr. Withers, great care will be taken not to destroy a single ancient feature of the church, or to do more than is necessary to preserve the fabric, or to restate work wantonly destroyed. The church contains five bells, and is dedicated to St. Peter and St. Paul.

RESIDENCE AT HAMPSHEAD.

We give this week perspective views and plans of the residence and stables recently erected for H. Gainsford Gotto, Esq., near the top of Child's Hill, Hampstead. The buildings are faced with Malm bricks, relieved with bands of bricks of a dark brown colour. The stonework is Portland, and the roofs are covered with Staffordshire tiles. Half-timbered work is introduced in the upper part of the tower, and in the gables and dormers of house and stables. The greater part of the house is carried up three stories high, a billiard-room 27ft. by 18ft. being formed on the top-floor over the dining-room. The stables are built at the entrance to the property, and are so arranged that the rooms on the first-floor shall accommodate the gate-keeper. An outside staircase is provided for access to these rooms. The cost of the buildings when finished will be about £4,200. The work has been carried out by Mr. Stanley G. Bird, from the designs of Messrs. George Lansdown and Harries, of 2 and 3, Warwick-street, Charing-cross.

PREMISES AT CORNER OF NEW BOND-STREET AND CONDUIT-STREET, W.

This important addition to the street architecture of London, from the designs of Mr. John Thos. Wimperis, of Sackville-street, Piccadilly, has just been completed by Mr. Wm. Brass, of Old-street, City. The position of ancient lights of the adjoining buildings caused a great deal of delay and trouble, and necessitated a flat roof being used. By the introduction of angle turrets, and chimneys with the parapet broken up by pediments, a varied skyline has been obtained; the angle turret especially being very picturesque, and is, without doubt, a most striking feature from whichever way it is viewed, and particularly when going down Bond-street. The upper story of this turret, as will be seen by our illustration, is formed into a loggia. The carving throughout is of a very effective character, the whole being a treatment of conventional foliage, typical of the business to be carried on, which is that of Messrs. Cadbury and Pratt, cheese and butter merchants. Ornamental iron balconies have been introduced, and add to the effect. The materials used generally throughout, are Portland stone and red bricks, with red Mansfield subbase, and Forest of Dean plinths to the pilasters of shopfront. Great attention has been paid to thoroughly ventilating the shop and basement, owing to the peculiar character of the business, and the shop has been fitted with wainscot counters and office fittings of good character. The walls and other portions are executed in coloured marbles, with a pitch paralled ceiling of good design.

ROYAL ACADEMY SILVER MEDAL DRAWINGS.—DETAILS OF SOMERSET HOUSE.

In the BUILDING NEWS for January 3rd last we published the general drawings of this interesting gateway, of which Sir William Chambers was the architect, by Mr. R. W. Gibson, for which he was awarded the Royal Academy silver medal last year. To-day we publish some of the enlarged details: by these the elegance and beauty of the design may be clearly seen and studied. Such drawings as these will always be of value, and we are glad to present them to our readers. We hope shortly to give a drawing in detail, also by Mr. Gibson, of the York Stairs at the bottom of Buckingham-street; a work so neglected that its present condition is a disgrace to our Board of Works.

The foundation-stone of a new Wesleyan chapel was laid at Perranwell, West Cornwall, on Monday. The edifice will be Early English in style, and will be constructed of local stone, with granite dressings near the base, and Bath stone in the upper portions. Beneath the chapel, which will measure 70ft. by 42ft., will be a schoolroom and vestries, and at the back of the rostrum will be a minister's vestry, choir-room, and heating chamber. The chapel will be surrounded by galleries approached from the lobby by stone steps. Mr. James Hicks, of Redruth, is the architect, and Mr. J. Blight, of the same town, the builder. The contract has been taken at £1,700.

New Wesleyan school buildings have been opened at Swinton, near Manchester. They have been built from the designs of Mr. S. Rawlinson, of Swinton, are faced with brick and stone dressings, and fitted up in pitch pine. Accommodation has been provided for 600 scholars, at a cost of about £2,200.

PARLIAMENTARY NOTES.

THE DEATH-RATE OF THE METROPOLIS.—Sir U. Kay-Shuttleworth, on Tuesday, asked the President of the Local Government Board whether it was true that the Registrar-General had reported that the death-rate of the Metropolis, which was 22.3 in every thousand in 1876, and 21.9 in 1877, had risen in 1878 to 23.5 in every thousand; whether this increase was almost entirely due to zymotic diseases; whether the death-rate had risen to a still higher figure in recent weeks (29.2 in that ending March 8th); whether Dr. Frankland had reported that during the past year the quality of water delivered by the companies who derived their supply from the Thames was inferior even to the unsatisfactory water-supply of recent years; and whether the Local Government Board had taken any action in consequence of these reports. Mr. Selater-Booth said, in reply, that the death-rate of London was 23.8, 22.3, and 21.9 per thousand in the years 1875, 1876, and 1877 respectively, and it rose to 23.5 in 1878. During the first ten weeks of this year the death-rate had been 26.3 per thousand. The average annual death-rate in London, taking the last eight years, was 22.8, against 22.6 and 24.3 in the two preceding decades of 1861-70 and 1851-60 respectively. About one-third of the increased death-rate in 1878, as compared with the exceptionally low rate in 1877, was due to zymotic diseases, and those were principally whooping-cough and diarrhoea. The annual zymotic death-rate in London from 1871 to 1878 had averaged 4 per thousand, against 4.5 and 4.9 in the two preceding decades. In reference to the next question, Dr. Frankland had reported that, with the exception of 1872, Thames water last year was more polluted than during recent years, but that was owing to the excessive floods rendering filtration exceedingly difficult. The monthly analysis of 1878 showed that out of 60 samples of water from the five Thames companies 40 were clear and transparent, whereas in the six preceding years of the average samples taken 42 were clear. The Local Government Board had no power to enforce the supply of water from fresh sources, but they had not failed to impress upon the companies the necessity of adopting all available improvements, and during the last two years the five Thames companies had expended upwards of £400,000 in constructing improved reservoirs, and these works were now either completed or in an advanced state.

THE LOCKS SUPPLIED TO THE WAR OFFICE.—Mr. Macdonald on Tuesday asked the Secretary for War if his attention had been directed to a correspondence in respect to a contract for locks furnished to the War Office, in which it was stated that a person furnished locks at a very large per centage above purchase price; whether he (the Secretary for War) had taken any steps to find if these allegations were correct, whether there was any particular reason why that tradesman was selected to supply locks, and whether it was correct that cast-iron locks were not used in the department till the contract was in the hands of the contractor in question?—Colonel Loyd Lindsay: Perhaps I may be allowed to answer that question in the absence of right hon. friend? Attention has been directed to the matter referred to, and for the information of the hon. gentlemen opposite I am prepared to state that the Secretary for War has had his attention called to the purchase of those locks, and the result has been to show that the locks were purchased from Mr. Hill at a printed price, not in excess of the ordinary retail price at which they are sold. The reason Mr. Hill was selected was because the locks he sold were considered well adapted for the purpose required. As to their being made of cast-iron, it has not been the practice to purchase locks made of cast-iron; but English manufacturers admit that if cast-iron locks were of good quality there was no objection to their being of that material.

On Saturday an official visit of inspection was paid to the harbour works of Newhaven by the directors of the recently-established company. The plans include immense sea-walls, to form a break-water and harbour of refuge, so as to inclose an area of 39 acres around the mouth of the river. The works are being carried out under the superintendence of Mr. F. D. Banister, who explained the plans.

The Town Council of Bristol have under consideration the purchase, on behalf of the city, of the Avonmouth Docks.

THE "BUILDING NEWS" DESIGNING CLUB.

A COTTAGE HOSPITAL.

AS might have been expected, some members who have felt themselves competent enough to contribute designs for houses and cottages, have not entered the lists for the above subject—whether from inability or from lack of boldness we do not know. The truth is everybody fancies himself capable of planning a house, and the result is an overwhelming number of designs—good, bad, and indifferent. In the present instance a cottage hospital for five of each sex, with convalescent ward, rooms for surgeon and matron, and other necessities was required, and in response we have several designs, the bulk of which indicate considerable care in the drawings, but, as might be imagined, a want of the knowledge of sanitary detail requisite for the task. If our club is to be of value in the instruction of students entering the profession, it appears to us that the planning of such buildings is of far greater use than that of a more everyday kind, and for which large facilities exist. In glancing over the designs, it is not a little singular or un-instructive to remark that many of the best plans we have received are from those members of our club who have shown the least aptitude in the previous competitions, and especially in the artistic work. It is the more desirable we should call attention to this fact, inasmuch as it shows that those with an artistic bent are often the least capable of any unusual labour or thought, as if the pleasure of their natural power ceased directly they applied themselves to labour they thought uncongenial to them. This we need hardly observe is the greatest error, and the reason why so many artistic members of the profession do not succeed in important public competitions. The greatest art in our opinion is that which can lend grace to the most prosaic work, the least—that which follows in the conventional groove. Hoping our little digression will be pardoned, we at once proceed to the designs before us, and here we have a confessedly difficult task to select a really suitable plan. The greatest weakness in those we have received is a want of simple arrangement and classification. The principal point seems to be a cottage-like, and, if possible, an informal kind of plan, in which the wards partake more of rooms, and the administrative offices resemble those of an ordinary dwelling-house. But, of course, this idea must not be carried too far; there should be a means of classifying the diseases; the pavilion principle should not be lost sight of in the wards, which should be well lighted and ventilated, and verandahs or other means of obtaining fresh air for the convalescents should be considered. There should be a small room or two for special cases of an infectious or acute nature, and there should be few, if any, long corridors. We cannot say that any of the competitors have realised satisfactorily these requirements. "Triangle in Circle," which we place first, makes a too-long entrance corridor to the wards placed at right angles to each other, at one end of building. The kitchen at side of entrance, though closed off by a screen, is inconveniently placed, and the convalescent room would have been better located somewhere nearer the main wards. On the other hand, there are a few good points; the wards, each 27ft. 6in. by 16ft. 6in., for five beds each, are well lighted and ventilated by side windows; the lavatories and bath-rooms at the ends are well placed, and the nurse's room at the angle between the two wards is convenient, inasmuch as one nurse may control both wards from her inspection windows, and attend to the wants of both classes. A special ward is provided, and the building is economically and simply grouped externally in an appropriate style. We do not like, however, the outer junction of ward-roofs. Fresh air is proposed to be admitted by Tobin's ventilators, and by the Manchester grate, and the foul air extracted by Boyle's ventilators in connection with combined smoke and ventilation flues. "Omega" has a fair arrangement of wards placed endwise, with matron's room between, and bath-room and w.c.'s at ends; the convalescent room, and verandah attached are convenient; but we think the operating-room too near the wards, and there is a want of skilful planning in the administrative part generally—the kitchen being absurdly out of the way. Style is suitable. "Be to its merits very kind," &c., adopts a more scientific classification; the sick-wards are placed at the ends of the front block, comprising matron's and nurse's

sitting-rooms; the entrance is in centre. Behind each ward is located a nurse's-room and convalescent ward; the lavatory and w.c. are placed in a projection from ward, but are not intercepted enough. There is a verandah leading out of convalescent-room; the latter has its separate w.c. at end of corridor which connects the two wings. Projecting in rear, opposite entrance, is the operating-room; a kitchen with side-covered passages to wards, scullery, and offices. The kitchen is thus isolated yet near, and at equal distances from each ward—a desirable point of economy. The author proposes air-ducts at sides of wards with vertical channels at heads of beds, central stove, concrete walls with timbering, and adopts a suitable style. We like less the alternative sketch. The cubing is put at 7d. and comes to £2,386. Considerable ingenuity in plan is also evident in "North West." The wards form the end of an L-shaped building, the kitchen and hall occupying the inner angle. The convalescent, nurses' bath-rooms, and linen-closets are well placed, and but for the want of a room for special cases, and attention to other sanitary details, this design stands well in the competition. Motto "J." is clever as an elevation. It is a single-story building with front verandah and projecting convalescent-rooms; the wards are judiciously divided at each end, one room being for three, and the other for two beds, but the conveniences are quite out of the way, and the kitchen and stores not central. There is a want, in short, of administrative convenience. The bird's-eye sketch is pleasing. "Yesram" places the wards at the ends of a long corridor with through ventilation and end light. They have four beds each, and one room for another bed adjoins; the closets project at side of ward; the convalescent-room and matron are in centre of block, but the kitchen is not central, and we do not know what the "administration-room" means. There is a great want of economy evident; the south elevation is designed as a suitable one-story range. "Norwich" fails in placing his closets and lavatories in the centre instead of on the outer side of wards; the kitchen offices are central in the rear; the matron's-room facing entrance is surrounded by corridor, side-doors closing off the male from the female corridors. There is a good principle evident in the classification, but a very hotch-potch external grouping is the result. Hot water and open fire-places are indicated. "Sin Circle" is a carefully executed set of drawings; there is nothing much amiss with the wards, which are pavilion, with intercepted closets; the nurse's and convalescent-rooms are convenient, and the kitchen is placed centrally, leading out of a large central hall. Considerable area is taken up, and a more condensed arrangement of the administration offices would have been better. The author shows the details of closet connection, and man-holes, and the mode of heating and ventilation. Open fireplaces and hot-water are combined with fresh-air inlets, the foul air finding vent in ceiling communicating with horizontal shaft and furnace flue. A Domestic Tudor style is adopted. The fault of "To be or not to be" is that the administrative offices are ill-proportioned to the wards. Why the prodigious building above, and where are the nurses' rooms? Wasteful of space, wanting in classification and economy of service are the general attributes of several other designs we have received, to which we can only refer as a class. "Such a Dog," "Anchor," "Con Amore," "Pecksniff," "M. with Leaves," "Try," "Omnia Vincit Labor," "Cyn-rac," "Melina," "Ogmore," "Cariose," "Olive Branch," "Signum," "G and J in Square and Circle," "Rusticus," "Amateur," "First Attempt," "Cyclops," "J.S.," "East Anglian," "Burswell," "Ich Dien," "Herat," "Elève," "Tam O'Shanter," "Essayez," "Amphion," "Ubique," "B. M. W." are of this number, though some very creditable drawings are to be found among them. The plans are either straggling or they show a building two or more stories high—with superposed wards—certainly a very undesirable mode of construction; in one case the author has a quadrangular arrangement, with centre garden and surrounding corridor, along which are ranged the several rooms. Another plan shows an angular disposition of wards forming the letter A. It would be impossible for us to criticise in detail the several plans. In many cases the wards are not provided with suitable conveniences; there is no linen-closet or nurses' room; the entrance is incon-

veniently near to the ward or kitchen, while the latter is placed quite a journey away from the patients; the operating-room, instead of being in a part of building shut off from the wards, is often unpleasantly near them, and there is a want of attention to other matters of sanitary importance.

DESIGNS FOR CHIMNEY-PIECE.

We have received numerous sketches for this subject, but we are sorry to say not one of them comes quite up to our expectations. "Memor Esto," which we place first, shows a chimney-piece of English Renaissance somewhat after the style of the Adams Brothers, the jambs being relieved by Ionic capitals, springing from inverted pedestal-like compositions. The frieze is festooned. Above the mantel-shelf the breast of chimney is adorned by a centre mirror, side-shelves, a coved top with space for china, and a broken pediment above. The treatment is quiet in effect, though the panelling is a trifle overdone. The author proposes French grey and white, the hollows to be picked in with gold, the cove to be in stamped gold leather. "Be to its merits very kind," &c. sends two designs both marked by simplicity of outline without extravagant or numbing ornament. We like the right-hand sketch the best with consoles to jambs. It is a Classical composition with pilasters and mirrors, divided into two tiers by a centre entablature, and without much projection. The decoration is confined to three shades of olive green with emerald mouldings to mirrors, varnished. The other sketch shows a bevel-edged mirror placed upright, quite square, with cove and shelf above, the sides having lockers and shelves for china, with glass panels between. The only fault we have to find with it is the want of depth of moulding at top. "Noah" sends a clever sketch with pier-glass, at the sides of which project cut brackets forming angular niches for shelves. An entablature projects over mirror, the upper surface intended for busts or vases. The chimney-piece is simply treated, of Sicilian marble, with a centre panel of Wedgwood and outer moulding. The side jambs show an inlay of green marble. We do not like the overhanging appearance of the angular shelves, though the general design is spirited. "Nemo" is too heavy in the jambs and upper pilasters; the Ionic pilasters are too wide; in other respects the design is quiet and not over-fussy, and the only place for brie-a-brac is on the top cornice, a deep cove surmounting the glass. "Veritas Vincit" is not devoid of merit in the simplicity of the fireplace and upper framing; the details are good, and the pillars and shelves light. "Owl" has also a very simple outline in the shelves above mantel, but spoilt by the cut fringes and brackets. Above the glass is an arched recess for china, lined with gold pattern stamped leather. We do not admire the whimsical iron dog. "Black Star in Circle" is spoilt by the side ramps which overhang the mantel-shelf, and the pediment is top-heavy; without these the design would have been appropriate. "Yes, or No" is simple and effective in the upper lockers and places for china, but the hollow below mantel-shelf, and the nondescript chimney-piece spoil all. "James" sends a plain and effective composition, but the brackets are tawdry. "T. W. P." is weak in the balusters supporting side shelves, and the design is over-panelled. "Maltese Cross" adopts a heavily framed glass with curved pediment—rather commonplace. "Steffano" is flimsy and the detail poor. "J. C. in Circle" falls into a rather stereotyped treatment of the upholsterer's type. "Pat" glories in a kind of acrobatic frontispiece; it puts us in mind of a wizard's table with magic bottles, wands, and inverted pillars. Why make the pillars diminish the wrong way? We must place "Amateur" in the same category. His sketch shows a projecting chimney-piece with heavy angle pilasters supporting huge brackets carried up to the ceiling. These are richly decorated, and over the glass is an elaborate arched recess for china. The whole conception is in a "loud" and ponderous style of ornamentation—a kind of mixture of Assyrian and Renaissance. Of other designs we can name only in order of merit—"Owd Nick," "K in Circles," "Club in Circle," "Try," "Through," and "Dagger," "Dunwich," "Signum," "Spider," "Ivy Leaf," "Belteshazzar" and "Ogmore." Many of the latter are in a nondescript kind of design, and indicate want of study of good examples.

The thirteenth annual exhibition of the Irish Fine Art Society has been opened at the Leinster lecture hall, Dublin.

GLASS.*

ANOTHER useful little art handbook has been issued by the South Kensington Museum authorities upon "Glass," written by Mr. Alexander Nesbitt, F.S.A. Like the previous handbooks, that of Mr. Nesbitt aims at giving the reader a clear account of the origin and history of the substance treated on as exemplified in the specimens at the South Kensington collection. An instructive chapter on the "Composition of Glass" commences the book, in which the chemical ingredients are pointed out and the various colours used in the manufacture of coloured glass. Thus we have it stated on Dr. Ure's authority that common window-glass is a compound of silicate of soda and lime, sometimes also of potash; and that plate glass contains silica, soda or potash, lime, and alumina. Venetian glass, it is stated, was made "like Roman, principally with soda; but it appears from the receipts given in some 15th-century manuscripts, which have been recently printed, that a mixture of potash obtained from the lees of wine was used. In France potash procured from fern seems to have been the alkali used throughout the middle ages." Speaking of the colouring powers of different bodies, M. Bontemps, at the British Association meeting at Birmingham, showed "that all the colours of the prismatic spectrum might be given to glass by the use of oxide of iron in varying proportions, and by the agency of different degrees of heat; the conclusion being, that the colours are produced in their natural disposition in proportion as the temperature is increased. Manganese, copper, silver, gold, and charcoal were all found to produce corresponding results; gold, for instance, giving a great many tints, varying from blue to pink, red, opaque yellow, and green."

Sketches of the history of glass are given, including Egypt, Phœnicia and Greece, Rome and provinces, Byzantium and the eastern provinces, Persia, India, Italy, France, Spain, the Low Countries, Germany, British Islands, and China, and from these many interesting facts may be learned. We see the author refers to Dr. Schliemann's discoveries at Ilium and Mycenæ; and observes that while no fragments were found at the former place, Dr. Schliemann mentions some discs of glass, believed to have been door-ornaments, he had discovered at Mycenæ. These discs, Mr. Nesbitt says, appear to be of the same character as those found at Ialysos in Rhodes, which vary in size from that of a sixpence to a florin, having rosettes pressed from a die. Dr. Schliemann, however, expresses a doubt whether some of these discs are not made of pottery. Mr. Nesbitt's chapter does not give the reader any account of the imitations of precious stones which the Egyptians are known to have made, nor that the glass made was generally opaque—a fact that accords with Dr. Schliemann's discovered relics. The fact stated by Stuart and Revett, that in the capitals of the portico of the Temple of Minerva Polias a torus inlaid with coloured glass was found is alluded to. The remarks on Roman glass will be found to contain much that is interesting. At South Kensington many examples of Roman coloured glass may be seen, comprising opaque red, and glass imitating jacinths, sapphires, glass, black, &c., with the exception of murrhine, described by Pliny, but which appears to have puzzled classical scholars to define. It is probable, the author says, that murrhine was a variety of agate containing shades of red or purple produced by heat as in onyxes. This chapter is illustrated by some ancient glass bottles of globular or pear-like shape; one of them represents a species of reticulated pattern made by combining sticks of various colours resembling the Venetian "mille fiori." These are of every conceivable shade and hue in combination, violet being the ground colour generally. Allusion is made to gems, cameos, and ornaments, and to the opaque red glass, and amethystine found embedded in pavements in combination with marbles, as in the House of the Fawn at Pompeii. Pavements of green glass about the thickness of a tile have been found at the Isola Farnese, near Rome, and many of these fragments have been discovered in explorations in many old towns—London especially. Walls were similarly lined, and specimens are to be seen at South Kensington, Nos. 886 to 895, '75.

In some cases figures of animals and men were represented, but patterns seem to be commoner. Glass for windows is briefly referred to. Lactantius in the fourth century refers to it, and slabs of marble, with small apertures formerly filled with plates of glass, still exist in Rome. Some beautiful enamelled Oriental specimens are illustrated; of these we may mention enamelled lumps of the Byzantine period, found in the mosques, examples of which are to be seen at Kensington. They have rich diapered patterns or arabesques, with birds and animals. The Glass of Italy is an interesting chapter. We quite agree with the author that the "vast undertaking of covering the interior of St. Mark's Church with mosaic had a most important effect upon the supply of glass in Venice; for if the manufacture already existed it would unquestionably receive a great impulse; if it did not exist, the presence of Byzantine artists and workmen skilled in such matters would lead to the discovery that the 'lagunes' possessing abundance both of fine sand and of maritime plants yielding alkali were well fitted for the seat of a manufactory of glass. Early in the 13th century it is clear the Venetian glass manufactory had become one of considerable importance, the taking of Constantinople in 1204, having contributed to that result. Documentary evidence of the regulations imposed on the various sections of glassworkers corroborates this fact. One interesting incident is recorded. In 1376 it was enacted that the marriage of a noble with the daughter of a "vetrajo" should not impede the descent of nobility to the offspring; and on the 15th March, 1383, a set of regulations were issued with the view expressed in preamble, "ut ars tam nobilis stet et permaneat in loco Muriani." A few unique specimens are engraved, as a Venetian beaker, a ewer, a jug of "mille fiori," and a grotesque vessel. During the 16th and 17th centuries the Murano glass was noted throughout the world; but in the 18th century the manufactories of England, France, and Bohemia began to compete with it, and the fall of the republic hastened its decline. The secret of the beauty and lightness of the Murano glass has never yet, it would appear, been divulged, though its strength is said to depend much upon its containing lead, like our flint-glass. A very interesting section is that devoted to the glass in the Low Countries and Germany. The engraved specimens of drinking-vessels with raised bosses are particularly unique. Coming to our own country, the subject is briefly sketched, and the earliest positive evidence of glass-making is supposed to be a contract made in 1447, when John Prudde, of Westminster, covenanted not to execute the windows of Beauchamp Chapel, Warwick, with the "glasse of England," showing that an inferior kind of glass was made, and that the Low Countries and France, together with the Muranese, supplied our wants largely at this period. Soon after, however, in the following century, Venetian glass appears to have been made in England, at the Crotchet Friars in London, if we can trust Stow and other evidence. But we cannot in this short notice give other incidents, and must refer our readers to Mr. Nesbitt's book, which will be found a concise and popular manual upon this most interesting art manufacture, and no student who visits our national collections of glass should go without it.

ROMAN ANTIQUITIES IN GLOUCESTER-SHIRE.*

A SMALL quarto volume upon the Roman constructions explored in Lydney Park by the Hon. C. Bathurst in the early part of the present century has just been published by C. W. King, M.A., Fellow of Trinity College, Cambridge. The Roman station in Lydney Park is situated about a mile and a half from the western side of the Severn, about twenty miles below Gloucester. The position is skirted by a range of hills, and the Romans found it a commanding site, as communication with the other fortresses on the opposite side of the river could be maintained by signals. In 1805 the foundations of old walls were accidentally hit upon, and the Hon. C. Bathurst determined to continue the excavations, which were carried on

for some years. The walls were laid down on plan, the pavements were copied, and a whole range of buildings occupying an area of upwards of 300 feet square was revealed. These contained—first, a residence in square form, with an atrium in the centre, surrounded by a cryptoporticus; the pavements of the apartments and galleries, found in fragmentary pieces, were of mosaic of exceedingly elegant patterns of Græco-Roman design, in blue and red tesserae. Coins of several Roman emperors, extending from Augustus to Arcadius, were also discovered; and these are carefully catalogued in the book. Another portion of the buildings was probably used as baths, while a third part found is clearly the foundation of a temple, 93ft. by 76ft. The late Mr. T. Bathurst prepared a summary of the discoverers' description, and the present editor has added notes which make the original memoir of still more interest to the archaeologist. Mr. King advances many theories bearing upon these discoveries, pertaining to the dedicatory inscriptions, and the nature and powers of the deity to whom the temple belonged. The plates illustrating Mr. King's edition are numerous, though some of them are not equal to the occasion, and are drawn with an uncertain hand. The tessellated pavements are certainly fine examples. They consist of tesserae of white and blue lias, and of broken tile for the red colour. The designs show *guilloche* borders, intersecting squares, circles, imitation of matting, and beautiful curvilinear forms. In all of them the blue is the predominant colour, and, altogether, they are very striking specimens of Roman paving. Plate 8, the "Oracle of Nodens," shows a singular circular opening in the pavement, which the author thinks was intended to receive libations poured to the "God of the Deep"; these were drunk up by the dry soil beneath. In the description to Plate 8, "The Dedication," the editor supplies the missing letters of the inscription, and makes it read as follows:—"To the greatest God, for the second time, Flavius Senilus, Head of the Religion, has erected this, from voluntary contributions, the Director of the works being Victorinus, interpreter for the Latin tongue." The relics comprise combs and knives, in iron and bone, wheels, ornaments in bronze. Plate 18 shows a view of the hypocaust under one of the rooms. Iron lamp-stands, implements, namely, a hoe, hatchet, and axe, are also illustrated, but the most interesting of all, probably, are the terminal figures in Plate 30, to which an appendix is devoted. The Roman origin of these figures has been disputed. They are really "Hermæ," colossal busts, on plinths of solid stone. One is a faun, the other a lady, but both have lost their noses. Mr. King thinks the lady's coiffure indicates exactly the age of the rebuilders of the temple, though others have assigned them to Renaissance times. He, however, believes the Lydney Hermæ "stood before the pilasters, bearing up the pediment of the Temple of Nodens, in company with two or four others." As a scholarly description of this British Pompeii, we commend Mr. King's work to all lovers of antiquity.

The restoration of St. Peter's Church, Sowerby, near Halifax, has been carried out during the past few months. The roofs have been repaired, and the whole of the plaster ceiling of the nave renewed. The old square pews of oak have been removed, the woodwork being re-used as open seats, and the three-decker pulpit and reading-desk has been replaced by more suitable furniture. The organ has been removed from the west gallery to the east end of north aisle, and at the corresponding end of the south aisle a vestry has been formed. The floor of the chancel has been raised, and the passages throughout the church will be laid with tiles. Heating apparatus by Lunley, of Halifax, has been laid down. Mr. Middleton was the architect, and the works have been carried out by Halifax contractors, the masonry being taken by Mr. Crawshaw.

On Wednesday, Feb. 26th, the memorial stone of the new East Cliff Congregational Church, Bournemouth, was laid. The church will be 69ft. long, by 40ft. wide, without the entrances, but including the apse. Including the gallery, sitting accommodation will be provided for 650 worshippers, the pews being of pitch pine. The interior will be divided into two aisles. The building is to be carried out in white brick, with stone dressing and moulded brick reveals to windows. The tower will be 90ft. high. The estimate for the church and schools, not including heating apparatus, is £4,013. The architects are Messrs. Kemp-Welch and Pinder, and the builder, Mr. J. Pike.

* Glass. By ALEXANDER NESBITT, F.S.A. With numerous Woodcuts. Chapman and Hall, Piccadilly.

* Roman Antiquities at Lydney Park, Gloucestershire. A posthumous work of the Rev. W. H. BATHURST, M.A., with Notes by C. W. KING, M.A. London: Longmans, Green, and Co.

Building Intelligence.

BELVELLY, Co. CORK.—The tender of Mr. S. Thomas has been selected (in a limited competition), for erection of four pairs of farm-labourer's cottages, farm-house and school-house, on the Belvelly estate of Mr. Smith Barry (formerly M.P. for Co. Cork). The several works will be executed in Belvelly red stock bricks, Bower's white facing-bricks and moulded bricks being used wherever considered necessary. Roman pantiles will be used in the covering of the roofs throughout. The works have already been commenced, under the superintendence of Mr. Wm. H. Hill, Cork, the architect.

CLEVELAND.—On Thursday week the re-opening of the newly-restored church of Carlton-in-Cleveland took place. The new edifice, which is constructed from designs prepared by the vicar, is in the form of a cross, and composed of freestone from quarries in the neighbourhood. There are north and south transepts, each about 14 feet square. From the centre of the building rises a wooden bell turret, tapering to a point, and surmounted by a small metal cross. Accommodation is provided for 250 persons. The restoration has cost about £800.

COTTINGHAM.—A new Wesleyan chapel has been recently opened at Cottingham, near Hull. Accommodation is provided for about 600 persons. The building is in the Italian style of architecture, built of white bricks, and liberally relieved with Bath stone, giving it a handsome and massive appearance. The interior is fitted up with all the modern appliances for comfort and convenience. The front of chapel is inclosed with handsome iron fencing, gates, &c., with piers and walls in harmony with front of chapel. The cost of the building is about £3,000; and the scheme provides a large school and classrooms at the back of chapel, yet to be erected, at a cost of about £1,000. The architect is Mr. W. Ranger, of Finsbury-pavement, London. Mr. F. Blackburn, of Hull, is the contractor.

KILBURN PARK.—A new Bible Christian chapel was opened at Kilburn-park on the 9th inst. The chapel seats 500 persons on floor and in galleries. Ministers' and stewards' vestries are placed one on each side of pulpit, with lavatory and conveniences. The basement provides school room about 40ft. square, and w.c. arrangements for boys and girls, also kitchen, &c. The whole building is heated with air, by Truswell and Holden's apparatus. The entire cost of the building, including lighting, fencing, gates, &c., also architect's commission, is £2,500. Mr. W. Ranger, of Finsbury-pavement, is the architect; and Mr. John Allen, of Kilburn, the builder.

METROPOLITAN BOARD OF WORKS.—On Friday a deputation from St. Luke's Vestry appeared in support of a memorial asking the Board to advance or allow the Vestry to borrow the further sum required to complete the Golden-lane improvement. It was stated that £69,570 was still required to complete the works, upon which £105,780 had been expended. Mr. Richardson severely commented on the conduct of four or five members of St. Luke's Vestry, who had trafficked in land required for these improvements in defiance of the principles which should regulate local self-government. The memorial was referred to the Works Committee. A second deputation from the vestries of Kensington, Chelsea, and Paddington appeared in support of a joint memorial, asking the Board to rebuild the bridge over the Grand Junction Canal, in Ladbroke-grove-road, Kensal-green, which is narrow, inconvenient, and unfitted for the huge traffic which passes over it. The estimated cost was between £7,000 and £8,000. This was also referred to the Works Committee. The Hackney District Board were granted permission to borrow £10,000 for paving works; and permission was also given to the Chelsea Vestry to borrow £20,000 for wood paving. A loan of £2,976 was granted to Kensington for sewer works. In compliance with a memorial from Bermondsey and Rotherhithe, it was unanimously agreed to rescind a resolution by which consent was refused to the construction of any of the Southwark and Deptford Tramway Company's schemes, and the following lines of tramway were sanctioned:—From Old Kent-road along Bermondsey New-road and Grange-road to near Spa-road; from Grange-road along Spa-road to Jamaica-road; from Spa-road along Jamaica-

road, Union-road, Deptford Lower-road to Plough-road; from Plough-road along Deptford Lower-road and Evelyn-street to New King-street; and from Spa-road along Grange-road, Blue Anchor-road, Raymouth-road, Rotherhithe New-road, to Deptford Lower-road. It was agreed that the experiments with the electric light on the Victoria Embankment be continued by the officers of the Board, on reduced terms offered by the Société Générale d'Electricité, for a period not exceeding three months.

ST. SEPULCHRE'S CHURCH, HOLBORN-VIA-DUCT.—The works at St. Sepulchre's Church, which had been stayed for some time, were resumed on Monday, under a recent order made by Dr. Tristram, the Chancellor of the Diocese of London. Application, it will be recollected, was made by the churchwardens of the City portion for further powers, under a faculty granted for certain repairs, and the churchwardens for the Middlesex portion objected to the proposed alterations. The matter went before the Consistory Court and was adjourned, the learned Chancellor expressing an earnest hope that the parties would come to an arrangement. The parties went before the Chancellor a few days since, and a "compromise" was effected. A sum of £8,000 had been allowed by the Court of Chancery for the restoration or reparation of the church. By the order the Middlesex portion withdrew the objection, and both parties were desirous that the works should proceed in the manner agreed upon in the memorandum of compromise mentioned, with the exception of the lowering of the floor of the church being only one-half of the depth proposed in the plan.

TWESKESBURY ABBEY.—The restoration of this noble specimen of Mediaeval architecture has been in progress during the past few years, and is now approaching completion. A great change has been effected in the building by the removal of about an acre of two coats of whitewash, and the clearing away of pews, galleries, organ-loft, lath and plaster partitions, &c. The work in the choir, transepts, and ambulatories is now finished, with the exception of the laying of the tile pavement and the arrangement of the old stalls in their original position beneath the tower, with the organ above them on the north side. In the nave the stone vaulting has been thoroughly repaired, and portions of the old colouring renewed. The chapels round the apse have also been repaired where necessary, and a new roof added to one which has long been in a ruinous condition and cut off from the church. A considerable portion of the sum already expended was contributed by the inhabitants of Tewkesbury and the counties of Gloucester and Worcester. Upwards of £10,000 is still needed to complete the work, and enable the building to be opened free of debt in September next, which is the time fixed for the re-opening services. A meeting convened by a National Committee appointed in March, 1877, is announced to be held in the Library at Lambeth Palace (kindly granted for the purpose by the Archbishop of Canterbury) on Friday afternoon, the 28th inst., at which Sir Michael Hicks Beach, Bart., M.P., will preside. The object of the meeting will be to call attention to the progress and present position of the restoration of the Abbey, and to present a report of the work accomplished since the meeting held at Lambeth in March, 1877. Mr. J. Oldrid Scott, who is continuing the restoration commenced by his distinguished father, the late Sir Gilbert Scott, will also read a paper; and drawings, plans, and objects of interest connected with the Abbey will be exhibited in the Library.

The restoration of the parish church of Caversham is now being rapidly proceeded with. The old wooden tower has been demolished, and a substantial one, 56ft. in height, built of flint, has been raised in its place. When the alterations are finished, the sacred edifice will consist of a nave and two aisles. The style is Early English. The alterations are being carried out from plans prepared by Messrs. Morris and Stallwood, architects, of Reading, Messrs. Wheeler being the contractors. We illustrated the designs for restoration last year.

The great window in the south transept of Chichester Cathedral is being filled with stained glass. The window is a fine specimen of Decorated Gothic, and measures 47ft. by 27ft.; it was erected by Bishop Langton early in the 14th century, and was then filled with painted glass, which was destroyed when the city fell into the hands of the Parliamentarians. The new glass is being manufactured in France.

More than Fifty Thousand Replies and Letters on subjects of Universal Interest have appeared during the last ten years in the **ENGLISH MECHANIC AND WORLD OF SCIENCE**, most of them from the pens of the leading Scientific and Technical Authorities of the day. Thousands of original articles and scientific papers, and countless receipts and wrinkles embracing almost every subject on which it is possible to desire information have also appeared during the same period. The earliest and most accurate information respecting all new scientific discoveries and mechanical inventions is to be found in its pages, and its large circulation renders it the best medium for all advertisers who wish their announcements to be brought under the notice of manufacturers, mechanics, scientific workers, and amateurs. Price Two-pence, of all booksellers and news-vendors. Post free 2½d. Office: 31, Tavistock street, Covent-garden W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.
[Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.]

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 6s.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom for the United States, £1 6s. 6d. (or 60s. 40c. gold). To France or Belgium, £1 6s. 6d. (or 35s. 30c.). To India (via Southampton), £1 6s. 6d. To any of the Australian Colonies New Zealand, the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

N.B.—American and Belgian subscribers are requested to remit their subscriptions by International P.O.O., and to advise the publisher of the date and amount of their remittance. If the last-mentioned precaution is omitted some difficulty is very likely to arise in obtaining the amount. Back numbers can only be sent at the rate of 7d. each, the postage charged being 3d. per copy. All foreign subscriptions, unaccompanied by an additional remittance to cover the extra cost of forwarding back numbers, are commenced from the next number published after the receipt of the subscription.

Cases for binding the half-yearly volumes, 2s. each.

RECEIVED.—T. W. H.—W. V. G.—S. L. B.—W. D. M.—W. M. F.—H. and Co.

E. W. P. (Address the letter here. We do not know the price of the book. Write to Mr. Murray.)—A. S. Oldrid Scott. (Messrs. Allen and Son, 62, Tabernacle-walk, E.C., can give the information.)—A. A. (We do not know the publisher or price of the book named. A rough test for the presence of impurities in drinking-water is to mix therewith a small quantity of permanganate of potash: if pure, the water will remain of a pinkish tinge; if otherwise, it will turn a muddy brown. It is dangerous to use the same cistern for the supply of the water-closet and the ordinary wants of the household.)—E. Goff. (If the windows have a right of light by prescription, the owner can, doubtless, object legally to the raising of the opposite party's building.)—T. O. THOMAS. (We thank you for your commendations. We have no knowledge of the work you mention. There is a course of Practical Geometry and Plan Drawing by C. W. Pusley. Perhaps you mean this. If any such work exists, you might get it by applying to Messrs. Batsford, of High Holborn.)—CONSTANT READER. (Having given the final certificate, it is not usual for the architect to afterwards certify to the indiction of penalties, unless there are "extras" still unpaid.)—T. P. HIGGINS. (For carpenters, Newland's "Carpentry and Joinery," published by Blackie, will be found a useful book of reference. Weale's series has also some useful treatises.)

Correspondence.

"A NATIONAL STYLE OF ARCHITECTURE."

To the Editor of the BUILDING NEWS.

SIR,—In your issue of last week a correspondent, "19th Century," asks "Who is the successful designer of the present day?" and adds, "Not the architect, but the engineer." This is humiliating, and compels one to ask, Wherein have architects erred; and wherein have engineers surpassed them in the stability and beauty of their structures? I readily admit that the "engineer is a thinker, a designer and applicator of mechanical contrivances to meet present requirements." But is it not outside the bounds of truth to say that "The architect is a copying clerk to old forms?" The genius of the architect is to a great extent distinct from that of the engineer; but let "19th Century" look at the shop-fronts of the present day, with their iron columns and

large plate-glass windows; let him compare the light and inexpensive structure of our modern theatre with that of Syracuse or the Coliseum, and say if the architect of the present day is a "mere copy-clerk to old forms." We have a style of art exclusively our own; well suited to the social and commercial requirements of the present age. I quite agree with "19th Century" in his just censure of those who ignore or overlook the principles so faithfully carried out by the ancients, and who, regardless of principles, reproduce in Britain what was adapted only to the climate or constitution of Greece or Rome; but surely that gentleman is not himself so blind to principles as not to observe that in general the architecture of our day can claim originality consistent with principles. Like him (if I understand him aright), I am not an admirer of Queen Anne; but I contend that it was the logical deduction of reason that to a great extent suggested such a style. We know that both Greeks and Romans, as also the inventors of the Gothic style, constructed their buildings to suit the various building facilities of their times; and displayed their genius in the skillful manner of arranging and moulding their stones. English architects cannot command the stone quarries which they possessed—with them brick takes the place of stone; and surely it is an honour to the architect who invents and adopts a style suited to the materials at his disposal, and thus triumphs over the natural ugliness of brick. This, I think, is paying due heed to the principles of Art. I observe that in Scotland some architects are adopting Queen Anne, but simply because it is in place in England. It is a disregard of principles to introduce it into Scotland, where there is abundance of stone. I trust, therefore, that we will not again be told that architects are mere copy clerks. As to that unfortunate smoky fire-place, "19th Century's" remarks are quite in point; but if I could induce him to bring engineers down to the level of architects, I could furnish an instance where an engineer constructed a fireplace and neglected to give sufficient recess for the dog grate. The consequence was that it smoked annoyingly, and soon the ornamental arched lintel cracked with the excessive heat, necessitating more expensive alterations than the application of a glass smoke board. But it is useless and unjust to take such isolated mistakes as a reason for wholesale condemnation.—I am, &c., A LOVER OF ART.

STRENGTH OF PORTLAND CEMENT CONCRETE.

Sir,—Owing to the failure of a large number of cement concrete pipes used for the drainage in Bournemouth, an investigation as to the strength of the concrete took place, the results of which are valuable, and I herewith tabulate them. All the pipes were about two years old:—

Thirty-five tests upon the tensile strength per square inch on 2-25 briquettes.

lb.	lb.	lb.	lb.	lb.	lb.
145	290	355	420	456	480
213	339	368	430	473	491
239	340	385	431	475	505
273	344	392	440	475	529
283	350	393	450	475	554

Average 231 333 378 434 471 512 598

Ten tests upon concrete pipes 2ft. internal diameter, 2ft. length, 1½ in. substance, with central load.

No. 1 pipe	lb.	No. 6 pipe	lb.
" 2 "	1,818	" 7 "	2,520
" 3 "	2,772	" 8 "	3,360
" 4 "	2,520	" 9 "	3,192
" 5 "	2,853	" 10 "	3,924
" 6 "	2,683	" 11 "	3,360

Average 2,536 Average 3,091

Ten tests upon tensile strength per inch of pipes of the above pipes similar in number.

No. 1 pipe	tensile.	No. 6 pipe	tensile.
" 2 "	213lb.	" 7 "	239
" 3 "	239	" 8 "	243
" 4 "	243	" 9 "	246
" 5 "	246	" 10 "	249
" 6 "	249	" 11 "	254
" 7 "	254	" 12 "	259
" 8 "	259	" 13 "	263
" 9 "	263	" 14 "	267
" 10 "	267	" 15 "	271
Average	233	Average	233

Six tests upon compression.

No. 1 pipe	per square inch compression.
" 2 "	2,684lb.
" 3 "	3,672
" 4 "	3,955
" 5 "	2,825
" 6 "	4,340
" 7 "	3,250
Average	3,454

The above tests were made on behalf of the manufacturer, and are the most favourable tests he could obtain.

The tests upon the five pipes, and giving the tensile and compressive stresses of the concrete of each of these pipes are exceedingly valuable, as it furnishes two methods of ascertaining the transverse strength of the concrete: one by direct investigation of the transverse strain exerted on the pipes by the load; the other by calculation from the average tensile and compressive stresses, and it speaks well for the accuracy of these tests that both these methods give the same result of 1·8 as a divisor to convert tensile into transverse stresses or a multiplier to convert transverse into tensile stresses. Some other tests were made not upon the behalf of the manufacturers, and these tests did not give so favourable results as to the strength of the concrete, and are as follows:—

Three pipes sealed at the two ends and burst with water.

No. 1 pipe	per square inch tensile.
" 2 "	96lb.
" 3 "	160
" 4 "	224
Average	160

Five tests on the transverse strength per square inch, and converted into tensile by multiplying by 1·8.

lb. per square inch transverse	lb. per inch tensile.
57·4	= 103
67·0	= 102
98·3	= 178
113·4	= 204
114·0	= 205

Average 90 Average 162

From the whole series of tests it is evident the difficulty of obtaining uniform strength of concrete in these concrete pipes had not been overcome, and there is no wonder their use led to such disastrous results, when the strength varies so much as from 1 to 7, and even averages of five samples vary nearly in the proportion of 1 to 4. The tests are, however, most interesting on account of the very great strength of some portions of the concrete; but until some steps can be taken to obtain uniformity of strength the lowest strengths will be those upon which to base construction. A. C. P.

DISTRICT SURVEYORS' FEES.

Sir,—When I wrote respecting the above, I did so hoping to elicit a somewhat more unbiased opinion than that of the plaintiff, as to whether in the event of more than one contractor being employed at the same time, in making alterations to the same building, the District Surveyor was entitled to a notice and a fee from each. Mr. Kerr's statement that "each builder becomes liable for his own fee" does not convince me. True, Mr. Newton ruled that Messrs. Adams should have given notice; but take a similar case, Kerr v. Strode, and it will be seen Mr. Knox ruled the reverse, stating the Building Act was passed for the protection of the public, not for the multiplication of fees. Of course Mr. Kerr says "the law is that Messrs. Adams shall give the district surveyor notice," Mr. Newton having given decision to that effect, and of course Messrs. Adams would say it was unnecessary, Mr. Knox having decided a case favouring their views. In the midst of conflicting opinions, I was in hopes someone would have quoted a case from a superior court showing what "the law" really was. When I know this, I for my part shall be quite ready to see that district surveyors, amongst whom I number many friends, get their legal dues, and not "a substantial abatement only,"

for I am well aware that in many cases the authorised fee is an inadequate remuneration. Mr. Kerr says he cannot accept my account of the facts, but does not attempt to refute it. He also asks "supposing the Club House had been burnt down, would the district surveyor have been responsible for negligence, under Messrs. Wontner Smith's notice?" I answer, Certainly not; for let the notice be perfect or imperfect, no such responsibility rests with the district surveyor, and I challenge him to produce an instance where he or any other district surveyor has been so held liable; moreover, I may inform him that the usual insurance for extra risk whilst workmen were employed was paid, and that the contract for steam-piping and cooking apparatus, particulars of which he had so much difficulty in obtaining, simply because he never asked Messrs. Adams, myself, the clerk of the works, or foreman, consisted merely of one new hot closet and steam-pipe to same, repairing and replacing another hot closet, and supplying a small gas-oven; that the pipes supplying steam to the hot closets could not by any possibility ever set fire to wood, even if touching it, can be seen at once by anyone understanding such matters, and is proved by the fact that for upwards of twenty years the pipe from which Messrs. Adams brought a branch to supply the new hot closet has touched wood without even scorching the paint, the boilers being worked at a pressure of from two to three pounds only. Mr. Kerr also alludes to what he calls my "shabby quibbles." This is scarcely courteous language for one gentleman to use towards another; but I can well afford to let it pass. His hope that I may myself one day be a district surveyor is doomed to be frustrated, for if there were half a dozen contractors employed on every building, and a fee paid by each, I must say I am too fond of my profession to give my time to the mental struggles involved in attempting to interpret the mysteries of the Metropolitan Building Act. If this statement renders his case the stronger, I am happy to give him the benefit of it.—I am, &c.,

HUGH ROUMIEUX GOUGH.

COLOUR IN ARCHITECTURE.

Sir,—I was pleased to see the letter from Mr. Hughes, explaining further your report of a paper read upon the above subject by Mr. J. W. Tonks, before the members of the Birmingham Architectural Association. Mr. Hughes tells us that Mr. Tonks was certainly at fault in mistaking red-stone for terra-cotta at the Grand Hotel, but that it was a mistake "not worth notice." If Mr. Hughes should ever be tempted to put in red-stone with the idea that it will retain its colour like terra-cotta, he will find in the course of a few years that he has made a mistake worth a good deal of notice. The stone in that time will be as dull as rusty iron, while the terra-cotta would have remained nearly as bright as ever. The same thing applies to granite and coloured marbles: the former will retain its colour, the latter will not. I repeat that Mr. Tonks was misleading your readers when he said it was but little affected by the atmosphere. It should be borne in mind that your journal is accepted as a useful medium of education by thousands; and that, therefore, it is the duty of everyone who detects an error to correct it, before others of less experience have time to commit themselves.—I am, &c.,

A BIRMINGHAM READER.

In the porch under the tower of the new parish church of St. Mary, Newington, S.E., have been placed some relics of the old structure, demolished to widen the roadway of Newington Butts. These include a font of yellow marble and oval in shape, and a massive chandelier, consisting of a centre stem, crowned by a life-size figure of a dove with out-stretched wings, and beneath are three rows of eight arms to support candles; the chandelier was made in 1726.

Premises for an institution for the blind have been erected in Lonsdale-street, Carlisle, and will be opened in a month's time. They have been erected from the designs of Mr. C. J. Ferguson, of that City, at a cost of about £3,000. Mr. Milburn had the building contract, Mr. Davidson that for joinery, and Mr. Johnson that for plumbing.

A new Foresters' hall has just been erected in Great Shaw-street, Preston, from the designs of Mr. Grant of that town. The building is French Classic in style, and contains a meeting-room 65ft. by 27ft., besides reading, secretary's, and three court-rooms. The contracts for erection were let to local tradesmen.

Intercommunication.

QUESTIONS.

[5709].—**Perspective.**—Will any adept at interior perspective tell me upon what line on his picture he places his heights, whether upon the nearest point to the eye on the horizontal line, or upon the station? Also, whether he can recommend any good work upon the above?—*INTERIOR.*

[5710].—**Transparent Varnish for Steel.**—Will anyone kindly inform me of the best transparent varnish for polished steel, to protect it from going rusty and dull, and how to apply it.—*W. S. W.*

[5711].—**Cricketer Pavilion.**—Our club contemplate erecting a superior permanent building. Which are the best and most complete pavilions in London or the neighbourhood? Are there any specially good ones in the provinces?—*COUNTRY WICKETS.*

[5712].—**Lift.**—Can any reader recommend a simple dwelling-house lift (from basement to ground floor only) for a 2ft. 6in. square inside diameter; height 13ft.—*HOIST.*

[5713].—**Wood Worms.**—Would a correspondent advise me what I should do to a piece of antique furniture to rid it of this infection?—*A. C.*

[5714].—**Deficient Quantities.**—In *THE BUILDING NEWS* of September 21st, 1877, there is a question asked by "A Builder" (5132) whether he could recover from a surveyor or proprietor for deficient quantities, and it is answered in the following number, 28th September, 1877, by "Nicholi Filius" to the effect that in a trial, "Coker v. Young" it was held a builder could not recover in such a case. I should deem it a great favour if the gentleman who replied could let me know in what court the case was tried, and who was the surveyor, and his address, or any information that would lead to this. An early reply would greatly oblige.—*W. D. B.*

[5715].—**Staybars v. Stained Glass.**—Will some of your influential readers correct me if I am wrong upon the following questions, for I think they are of more importance to church architecture than many people suppose. I refer to the removal of staybars and stanchions, in order to fix a window of stained glass. I have known numerous instances of both staybars and stanchions being replaced by bits of thick wire inside the glass, to the utter ruin, as I think, of the window externally. I have known staybars of an old Perpendicular window, which had been in place, and firmly loaded hundreds of years, having been removed because a curate or a farmer's wife thought a stained glass window "would be so pretty." I have known a substantial bar connecting and tying the wall plates of a chancel roof, through the springing line of an east window, sawn out to put in very inferior glass. Now, I would ask, 1st. Is it necessary to remove substantial staybars and stanchions in order to insert stained glass? 2nd. Can any artist be found who will acknowledge the ironwork as a necessity, and design his glass to suit it? 3rd. Am I right or wrong in supposing that an old window would be better without the glass than with it, at the loss of the ironwork, and the introduction of a wire tell concealing half the mouldings, and plugged into the stone with great lead plugs? My policy has been of late to persuade all my clients, where I could do so, to be contented with simple geometrical glazing, of such a character as does not necessitate the removal of the ironwork, instead of allowing the stained-glass painter's assistant to damage the architecture externally. I think there will be found many of your readers who have experienced the same difficulties as I; but, if not, I shall be thankful to be set right.—*ARCHITECT.*

REPLIES.

[5701].—**Sewerage.**—The inclination at which "tumbling bays" become necessary, depends, of course, upon the size of sewer to be dealt with, for small sewers require greater velocity of discharge. For sewers of, say 2ft. or 2ft. 6in. diameter, in fall exceeding 1 in 500, should have tumbling bays, and these may be introduced about 300 yards apart, depending on gradient. I should have ventilating chambers at every tumbling bay; the outlets should also be protected by flaps to prevent inrush of air at lower end, and stack-pipes of houses may be turned to account to let out gases at different points.—*G. H. G.*

[5702].—**Sanitary Examination.**—I am not aware of any society, unless it be the Sanitary Institute. I should advise "Golumptions" to apply to the Local Government Board.—*G.*

[5707].—**Haslingden Flags.**—Situate on the hills between Haslingden and Rochdale, there are a goodly number of quarries, on the Haslingden side at Ewood Bridge, Haslingden, Rawtenstall, Clough Fold, and Stocksteads; and, on the Rochdale side, at Whitworth and Facit. In specifications it is usual to say Haslingden or Rochdale flags, sets and curbs. There are various qualities of flags, as best barns, second barns, and common barns. The term barns refers to their original use for barn floors, hence the name. The best barns are of solid rock and self-faced, but not always out of winding. The second barns are of the same rock, but not smooth-faced; the common barns are from the top rock; the sets and curbs are nearly always out of the best or bottom rock; the common barn rock is of a rough kind and shelly, and is used for inferior work. Machinery now plays an important part in preparing the material for the market by being polished and worked by a facing machine, similar to an iron planer. The gauges are 3ft. 2ft. and 2ft. and randoms. The stone is of a superior quality, and is of the second or flag rock of the Millstone Grit series, and is much more durable than Yorkshire stone for paving purposes. Rarely is any other stone used for street work in Lancashire than Haslingden or Rochdale.—*H.*

[5708].—**Hospital Planning.**—Blocks arranged "en echelon" is a term intended to imply that they are placed as a series of terraces, or arranged in step-like order.—*G. H. G.*

[5709].—**Hospital Planning.**—The term "en echelon" can be best explained by supposing the plan of

blocks to assume on ground a diagonal arrangement of parallel blocks, or the appearance of steps without risers, seen in side elevation. I do not know the advantages of the system.—*LUTU.*

[5699].—**Driving Sewer Headings.**—If the sewer is 15 feet deep or more, put up a windlass to pull the dirt up shaft. Sink the shaft 12ft. x 3ft. 6in. in the clear; put wallings in according to the height of ground, 2ft. 6in. or 3ft. apart. Stretch the shaft in centre from walling to walling to form a double shaft, so that one skip can work up and other down. Nail a strip of timber in centre of walling if a flat one, so that the bottom poling boards will lap 3 inches inside the top do. (If round not required); and in filling up the shaft, you can take out the bottom walling, and draw out the poling boards and save timber, and continue removing timber (as you fill up shaft) all the way up if the ground will stand. Nail a board on at each corner of the shaft to hang the walling, and prevent the skips from catching in the timber. Put a small prop in each corner of the shaft, between the wallings. The shaft to be sunk lengthways towards the headings. Put three props at each side of the bottom of shaft to support it, not quite upright, bottom of props leaning toward the sides of shaft, one at each corner, and one in the centre. If the sewer is 20 or 30 feet below the surface, shafts to be two chains apart if a small sewer; if a large sewer, 5 or 10 chains apart, according to size of sewer. Manholes to be put in at half distances for passing and repassing with skips for small sewers, such as 18-inch pipe sewers. Drive headings 3ft. 6in. high by 3ft. wide. Head tree to be 2ft. in clear, if sewer to be for 18-inch pipes. Props under head-tree to be 3ft. in clear at bottom. Distance from head-tree to head-tree according to quality of ground. Put poling boards from head-tree to head tree; the same in sides from prop to prop. Drive heading No. 1. Pull dirt up shaft. Lay pipes at farthest end of No. 1 heading; also begin to drive No. 2 heading. Take dirt from No. 2 heading, and cover pipes in No. 1 heading, and fill up. When No. 1 heading is filled up, lay pipes at far end of No. 2 heading. Lower dirt down shaft, and fill up No. 2 heading same as No. 1. The shafts should be sunk where manholes are required for cleaning cesspools. If large manholes are required, sink the shafts in size accordingly. If large sewer, sink shaft in size according. If dirt is to be pulled up by steam power, sink the shaft round with wooden curbs. Put poling boards in behind the curbs, and props between the curbs. At the bottom of shaft drive small heading, and put in piece of timber longitudinal to support the curb, length decided by width of sewer. Drive heading in centre of sewer, six longitudinal (called sometimes a bar) in centre of heading with prop at each end standing on foot block. Foot blocks should be put under all props. Widen from each side of centre of bar according to size of sewer required. If in quicksand or wet ground, put one bar each side of invert, and fix poling boards close together under bars, so that you can put masonry in centre of invert. Remove bars and continue with masonry; the quantity of timber required depending on nature of ground.—*JOHN J. WELCH, Tiverton-on-Avon, Bath.*

WATER SUPPLY AND SANITARY MATTERS.

STAFFORD.—There being a large influx of salt water into the deep-bore hole which the Stafford Corporation are sinking into the Bunter sandstones, in order to obtain a fresh supply of water for the town, the contractor, Mr. Richardson, has called upon the Town Council to assist in the extra expense occasioned by this influx into the well, which is now about 800ft. in depth. The Council refuse to recognise any liability; and on Tuesday it was agreed to refer the point to Mr. Bramwell, C.E., for arbitration.

At a meeting held at Dawlish on Monday, plans for a new cottage hospital, prepared by Mr. Bridgman, architect, of Torquay, were approved, and it was decided to erect the hospital in Stockton-road. The new building will contain on the basement an out-patients' room, committee-room, kitchen, and offices; on the first floor, male ward, female ward, lavatories, bath-room, operating-room, and matron's room; and above this three bedrooms. The total cost of erection and furnishing is estimated at £760 only.

On Friday morning the Mayor of Southampton, with seven members of the Town Council of that borough, and Mr. James Lemon, C.E., their consulting engineer, visited the sewage works at Taunton. The working of the system was explained, and a demonstration given of the process adopted for dealing with the sewage. The Southampton Corporation intend constructing sewage works, and desire to see how other towns have succeeded.

An inquiry was held last week, at Dover, before Mr. Terry, from the Local Government Board, respecting an application from the corporation for sanction to borrow £650 for sewerage purposes. The inspector said Mr. Rawlinson suggested that there should be a layer of concrete over the top of the sewers as a protector, and that if the town council required any additional sum for the extra work, they would be at liberty to ask for another £50. The borough surveyor accepted the suggestion.

The Royal Unity Lodge, M.U. Odd Fellows, Launceston, have decided to erect a new hall in the Western-road from plans prepared by Mr. C. P. Wise, of that town. They have accepted the tender of Mr. William Burt, also of Launceston, and the work is to be carried out forthwith.

Our Office Table.

THE Sub-Committee of the Sanitary Institute of Great Britain appointed to test the Cows exhibited at Leamington, having carried out an elaborate series of experiments, have arrived at results of great value. These, however, show the necessity of further investigating the whole subject of ventilation by automatic means. It is therefore proposed to extend the inquiry to other appliances for ventilation besides those already submitted to trial. By permission of the Kew Committee of the Royal Society the experiments will be carried out at the Royal Observatory, Kew. The Council have passed a resolution appointing Captain Douglas Galton, C.B., F.R.S., Rogers Field, B.A., M. Inst. C.E., and W. Eassie, C.E., as a committee to undertake such investigation with a view to the publication of the detailed results. The expense of the contemplated inquiry will be considerable, and the Sanitary Institute have not at the present time funds available for this purpose. It is therefore proposed to raise the requisite fund by special subscription among those interested in the thorough investigation of the subject.

On Wednesday evening, the 12th inst., the Liverpool Engineering Society held its usual fortnightly meeting. Mr. Thomas Duncanson read a lengthy paper on "Storing Water," which treated of the construction of large storage reservoirs. The author commenced by stating the principles on which the yield and capacity of reservoirs are determined, showing the most economical proportions between the two factors, then went on to consider the actual construction of reservoirs, the usual practice of hydraulic engineers being fully described, special reference being made to the Yarrow reservoir of the Liverpool Corporation, and concluded by pointing out the necessity for some national scheme for utilising the mountain or rainy districts of England and Wales for the supply of towns. The paper was well illustrated by diagrams and tabulated statements.

MR. SEYMOUR HADEN, whose gifts as a practical etcher are well known, is about to deliver at the Royal Institution a course of three lectures upon the theory and practice of the art. The lecturer will give a certain novel interest to his discourses by the introduction of practical illustrations of the various processes of engraving. In his first lecture he will deal exclusively with the value of etching as an unrivalled mode of expressing certain kinds of artistic truth, dwelling at the same time upon the need of its encouragement by bodies like the Royal Academy, which at present gives no kind of instruction in etching. In his second lecture, Mr. Haden proposes to etch a plate before his audience, in order to show them how the needle, by removing the ground from the copper, permits the acid to bite out the incised line from which the impression is afterwards taken; and in his third lecture he will have a copperplate press by his side, and illustrate by practical experiment the manner in which the printing is performed.

A PAPER was read last week at the Society of Arts by Mr. William Thomson, F.R.S.E., F.C.S., "On the Injurious Effects of the Air of Large Towns on Animal and Vegetable Life, and on Methods Proposed for Securing Salubrious Air." A great variety of chemical facts and valuable statistics were brought forward, mainly on the authority of Dr. Angus Smith, to show that not only is the air of our large towns much contaminated, but that these contaminations are very injurious to the health, happiness, and longevity of the people who breathe it. The best scheme as yet proposed for the abatement of this evil, Mr. Thomson thought, was that proposed by Mr. Peter Spence, F.C.S., of Manchester, who deemed it practicable to build a chimney 600ft. high, 140ft. external diameter at the bottom, and 100ft. internal diameter at the top, at a cost of about £10,000, thus providing for the perfect combustion of all the coal burnt in Manchester. It was understood that Mr. Spence's system, propounded more than twenty years ago, had been adopted successfully at the Manchester Assize Courts, and was to be applied to the new Law Courts in London. The first great advantage of the plan was its making the liquid and gaseous sewage to a great extent neutralise each other. Again, it would thoroughly

ventilate the sewers; and, lastly, it might materially help to solve the liquid sewage problem, as was explained in detail. The system might be cheaply extended to all our large towns by simply joining all the chimneys in each block of buildings together, and connecting them with one tall stack.

TENDERS were last week accepted by the Corporation of Leeds for the erection of a new "destructor" at Armley-road. A similar apparatus was erected about eighteen months ago at the Sanitary Depot, Burmantofts, and it is in consequence of the satisfactory result of this experiment that the Sanitary Committee of the Town Council have now determined to extend the system. The committee had much trouble and expense in disposing of the rubbish swept from the streets or emptied from ashpits. Residents objected to the refuse being "tipped" upon any vacant ground in the vicinity of their dwellings or places of business. This difficulty has, however, been solved by Mr. Fryer's patent, of which the Town Council purchased a license in May, 1877, after the system had been proved to work well in Manchester and other towns. As the patent carboniser at Burmantofts is equal to dealing with the whole of the animal or vegetable matter found among the market refuse or street sweepings, only a "destructor" will at present be built at Armley-road. The first-named apparatus comprises a furnace or kiln which converts vegetable refuse into charcoal, which is available as a deodoriser or manure, whilst the clinkers which result from the process of burning in the second case are ground up into an inoffensive powder, and this finds a ready market as mortar or for road-making purposes. When the rubbish is first collected, the fine ash found mixed with it is sifted out, and either sold separately or used as fuel in the subsequent stages of the process. Broken old pots, sardine or Australian meat tins, and other articles of metal are also picked out, cleansed by being put through the furnace, and after thus being partly fused, are sold as old iron. The remainder of the rubbish comes out of the destructor as clinkers, which are ground up in mortar pans, mixed with lime, and sold so readily that the supply at present does not meet the demand.

At a meeting of the Council of the Royal Architectural Museum, held at Westminster on Wednesday last, Mr. Joseph Clarke, F.S.A., resigned the office of senior hon. sec. to the Museum, a post which he has so ably filled for more than twenty-five years. The office also of treasurer, held by Mr. Clarke since the death of Sir Gilbert Scott, was also declared vacant. Mr. Clarke's resignation was received by the council with much regret, and the president, Mr. Beresford-Hope, M.P., explained that nothing but advancing years, and consequent pressure of domestic ties, had induced Mr. Clarke to tender his long-since-talked-of resignation, which was accepted with so much regret by all. Mr. John P. Seddon was unanimously elected in Mr. Clarke's place, to act as hon. sec. conjointly with Mr. Maurice B. Adams, and Mr. Walter Cocks was elected treasurer by acclamation. The reports of the classes and school of art, as well as of the sketching club, were read, and bore witness to the considerable improvement in the quantity and quality of work done; while, in connection with the club, it was announced that an endeavour is being made to arrange some Saturday afternoon sketching excursions during the summer months, Mr. Adams having consented to accompany the excursionists. The books selected by Mr. A. J. Pennington, the recipient of the five-guinea prize last year in connection with the club, were inscribed by the president, and Sir Walter James promised a similar prize of equal value this year. Messrs. Ewan Christian, J. P. St. Aubyn, Professor Lewis, Sir Walter James, and Mr. J. P. Seddon promised to attend in turn the meetings of the club held this session, on the first Wednesday in every month. The club now numbers about 40 members.

In these days of "Chippendale Chairs" and "Eastlake Tables," when "over-mantels" enrich our fireplaces, and blue plates the walls of our sitting-rooms, anything fresh in the way of furniture worthy of consideration, both from an art, as well as from a common-sense, everyday point of view, would, perhaps, seem scarcely possible. We have had Greek and Mediæval furniture, then Anglo-Japanese and Queen Anne, while the useful "Bentwood"

furniture is but a recent introduction. In spite of all these things, we are about to possess another "latest thing out," and really, judging from the specimens which we have just seen, the ingenious and useful "chair furniture" to which we refer, invented by Mr. J. Taylor the architect, of Westgate-on-Sea, will be welcomed by very many, at any rate for partial, if not for the entire, furnishing of their houses. The idea, like most good ones, is "the simplest thing in the world." One or two pieces of furniture, such as a chair and table, with a ledge or two, and a whole suite of furniture, can in a few moments be obtained. Thus, two chairs and a ledge, if we may so term it, and you have a bed on the same two chairs; two box-like cupboards, with another sort of ledge, and not only a useful, but in every way suitable, buffet or sideboard for a dining-room; and so on, with an almost endless variety of combinations, the whole series of individual pieces being at once in readiness for removal in the smallest possible time and space. For officers and others whose residence in one place must always be more or less of a temporary character, such furniture would be a considerable advantage, and although few people would perhaps care to make their houses into a sort of wizard's cabinet, yet most families have apartments in their houses known as "spare rooms," where convertible furniture such as Mr. Taylor's "chair system" would be most suitable. We hope soon to publish a series of examples of Mr. Taylor's invention, when our readers will be able to judge for themselves.

MR. WILLIAM HAYWOOD has made a report to the Street Committee of the Commissioners of Sewers upon the electric lighting experiment at the Viaduct. Beyond the details peculiar to the site selected the report is of no value whatever, and will not help to the solution of the problem whether the electric light can be economically applied in the illumination of streets. It appears from Mr. Haywood's report that the Jablochkoff system is "about $7\frac{1}{2}$ times as dear as gas-lighting," but the 16 electric lamps employed gave "about seven times more light than the 16 gas-burners." If illuminating power is made the basis of comparison the two lights are, therefore, practically equal; but, unfortunately, no photometric tests appear to have been made, and in estimating the lighting power of the Jablochkoff candles Mr. Haywood has taken the unsupported statement of the Société Générale as the basis of his calculation. Hence his report must be taken for what it is worth, and that is merely a proof that the electric arrangements cost $7\frac{1}{2}$ times more than the gas.

THE Society for the Protection of Ancient Buildings has been too hasty. The Dean of Norwich has been carrying out extensive works of reparation at Norwich Cathedral, including substantial repairs to the west front and the removal of the modern yellow wash from parts of the interior; these operations being executed in great measure at Dean Goulburn's cost, and under the supervision of the architect to the dean and chapter. In the course of the work of cleaning, a few square feet of decorative colouring were revealed on one of the arches at the east end, and have been left as a memorial to future generations. Some officious person unacquainted with the facts of the case, presumed that the old fresco thus uncovered was but the commencement of a scheme of colour decoration to be extended over the whole cathedral. Such an opportunity for advertising the Anti-Restoration Society was not to be neglected; the official machinery was set to work, and at once the honorary secretary wrote a sharp letter to Dean Goulburn protesting against the application of colour to the cathedral. The amusing point of the misconception is, that so far from the internal walls of Norwich Cathedral being in danger of deprivation of "the tender grey tints of age" with which they are invested in Mr. Morris's eyes, they are covered from plinth to vaulting boss with a hideously dirty yellow wash, spread over the entire surface in Dean Turner's time, some seventy years ago; this it is intended to remove, and so render visible the divisions of the stones in the Norman, and later work. A smart rap on the knuckles for the mistaken zeal displayed in his "very able if not modest dissertation" was given Mr. Morris at the meeting of the Norfolk and Norwich Archeological Society on Monday, and the Society has gained little by its precipitate interference.

THE Westminster and Pimlico Industrial Exhibition for the current session, is to be held

in a structure which is being built for the purpose, upon an admirable site lent by the governors of the Greycoat Hospital, in Westminster. This is between the Victoria Chambers and the Army and Navy Stores, on the south side of the street, opposite to the block of the "Members' Buildings." Mr. Seddon, who is vice-chairman of the committee, is acting as honorary architect; and has arranged four buildings, each 70ft. long by 20ft. wide, and 12ft. high to the eaves, around a quadrangular court 70ft. square. The buildings are being erected by Mr. Humphreys, of the Borough-road, upon his system of corrugated iron. The internal court will be covered with prepared canvas, tent fashion, but in three aisles, the central one 30ft. wide, and the side ones 20ft. It is expected that additional annexes will be required, as the applications for space are numerous. The exhibition is to be of workmen's handicraft, arranged in the following classes:—(1) Mechanical, (2) artistic, (3) general, (4) fabrics and fancy work, (5) work of children in elementary schools, and (6) of young persons under 18. The exhibition having been certified by the Board of Trade, the patent rights of all exhibitors will be protected.

THE Committee of the Central Association of Master Builders of London, in presenting their Report, congratulate the association on the successful termination of the "masons' strike" last spring, when the "Masons' Union," although it did not withdraw its demands, allowed its members, under certain conditions, to return to their work. The association is now entirely free from debt. Although it has only been in existence ten years, it has successfully resisted two most important strikes, besides doing other useful work. During the past year the association has joined the "National Association of Master Builders of Great Britain." In view of the recent struggle, and of the circumstance that the building trade of London has barely recovered from its effects, the committee would not at this time suggest any reduction in wages, but thinks some modification of the hours of labour might be advantageous.

Lamplough's Pyretic Saline is refreshing, most agreeable, and the preventive of fevers, biliousness, small-pox, skin diseases, and many other spring and summer ailments. Sold by chemists throughout the world, and the Maker, 118, Holborn Hill. Use no substitute. —[ADVT.]

ROOFING SLATES.

Reduction in Prices.

Send for price list to THOMAS R. ROBERTS, Slate Merchant, Conway, before ordering elsewhere. Slate slabs, eills, hearthstones, ridges, cisterns, and all other kind of slate work very cheap. —[ADVT.]

CHIPS.

The Free Library, Bradford, and also the Liberal Club in that town, have been ventilated with Messrs. Robert Boyle and Sons' patent self-acting air-pump ventilators, and we understand the result is satisfactory.

The gaol at Dorchester is about to be enlarged at a cost of £30,000. The work is to be done by convict labour, and Mr. G. Crocker, of Dorchester, has been commissioned to furnish the materials at schedule prices.

A memorial stained-glass window to the late Col. Coles has been placed in the Cowper and Coles aisle of Hastings Parish Church. The subject is Peter preaching to Cornelius.

Alterations and additions are about to be made to the Medical Schools, Cambridge, to accommodate students of human anatomy, and the Syndicate have approved Messrs. Tompkins and Sons' plans for the same.

Mr. J. P. St. Aubyn has been appointed as architect for the restoration of the fine Late Perpendicular Church of Gamlingay, Cambridgeshire, which is now in a state of great dilapidation.

New Government offices are being erected in King-street, Cardigan. The contract is being carried out by Mr. D. M. Williams, of that town.

The Norfolk and Norwich Hospital Committee have accepted the tender of Messrs. Lacey, of that city, at £44,450, for the erection of the two western blocks and the administration and operation departments of the reconstructed hospital. The work is to be commenced as early as possible.

The restoration of St. Mary's Church, Bungay, is about to be carried out from the designs of Mr. R. M. Phipson, of Norwich and Ipswich. The first contract, that for the restoration of the tower, has been taken by Mr. H. Nurser, of Bungay.

The Lancashire county magistrates have appointed Mr. W. H. Stevenson foreman of works at Whittingham Asylum. There were 115 candidates for the situation.

THE BUILDING NEWS.

LONDON, FRIDAY, MARCH 28, 1879.

DECORATION AND ARCHITECTURE.

WHILE the decorator and architect are so estranged from each other as they almost necessarily are under the present art regime, it is vain to expect from the former an acquaintance with certain principles of art that underlie what we may here for our present purpose call architectonic decoration. The absence of this knowledge, or rather concern for the architect's work, is painfully made apparent in almost every building in which the highest class of art decoration is not attempted. Panels in tints, borderings and stencilled patterns, scrolls and festoons arranged in a kind of rococo manner appear to be the stock-in-trade of the school of decorators we have now in view. Something must be said, indeed, for the latest fashion for dull and dingy colours. If rather sombre for our climate, they are sensible; our wall-hangings, carpets, curtains, wear well in them, and they do not lend themselves to that light and frivolous kind of decoration to be found in the saloons and cafés of Paris, and which under the term of "Louis Quinze" is even now extolled by some decorators as the acme of refined elegance. Such ornament we have long since relegated to theatres and music-halls, though even in the better examples of such places it is giving place to something less tawdry and superficial. In many of our recent restaurants and hotels the taste for borders, scrolls, &c., appears to be reviving—whenever, in fact, the money to be spent in decoration is insignificant in proportion to the extent of surface to be covered. Not a few recent buildings, including an hotel on a grand scale, threaten to call into requisition this kind of artistic trimming. The walls and ceilings must be covered with something, and the "scroll and panel" style—if we do so designate it—is the cheapest and most effective. Now it appears to us to be a great pity something less mechanical could not be substituted for this stereotyped kind of ornamentation, if only a ceiling or a room could be artistically treated. We do not suggest that a piecemeal plan be adopted, as a picture in fresco or mosaic undertaken in one part, leaving the other portions cold and bare. This plan, we know, is a favourite one with some artists; it is fragmentary, and always unsatisfactory. It is better to avoid pictorial wall-painting altogether, than to begin a scheme of subject-painting with but slight chance of completing it. A less uncertain mode of treatment is that of partial relief by flat retiring tints, or the use of coloured materials. In this kind of decoration everything depends on the harmony of the tints. Friezes, dados, spandrels of arches, and ceilings, naturally lend themselves to this mode of decoration, and it is rather to be regretted that architects have not encouraged the use of coloured stucco more than they have. Frescoes are admitted to assimilate better with architecture than oil-painting, despite the failures that have occurred in its employment in England; its very deficiency of depth and richness of colour, and the absence of glossiness, are unquestionably points rather in its favour than otherwise. Elaborately-finished oil-paintings, such as Delaroche's "Hemicycle," in the Ecole or Musée Beaux Arts, Paris, is quite beyond the province of architectural decoration—the cost about £30 a square yard, if we are to accept the figure from a well-known authority, being

equally beyond the reach of most people. The frescoes at Westminster are really a series of panel or easel pictures, and are pronounced by all competent judges to exceed the limits of decorative painting. If we would regain a true taste for decorative art that should be applied to architecture, and yet subordinate to it, we must go to Egyptian and Greek art for models. In both instances the idea of decoration was relief, flat, conventional ornament, or scenes from heroic or religious mythology. Even Greek sculpture was eminently decorative. The art of the 12th century and the Renaissance was also mainly decorative. It strove to preserve the graceful and pleasing in form and colour, and the attributes of realistic or "high art," as it is sometimes called, were always absent. If we seek to discover the rôle which painting played in the great historic periods of architecture, we shall find it following the architectural forms and subservient to them. The patterns from Egyptian ceilings given by Sir Gardner Wilkinson show a thorough knowledge of decorative combination in colours. The ceiling-patterns of the tombs were arranged in compartments, in which the favourite forms of the lotus, the square, circle, diamond, fret, scroll, and zigzag occur, and these were painted upon the stucco. The borders were plain lines or other devices in red, blue, or green. The shafts of the columns were covered with painted stucco. Red, blue, and green were predominant colours, but yellow and black are also seen, and these were used with a knowledge of the value of complementary juxtaposition or harmony. It is well known the paint was mixed with water and a little gum. The Greeks and Etrurians employed coloured decorations with equal, if not greater, delicacy; red and blue were used for grounds, and the celebrated frieze containing the Panathenaic procession, which encircled the peristyle internally, had a blue ground. In the mosaics of Hadrian's Villa at Pompeii, in St. Mark's at Venice, and the beautiful processional compositions found in the Ravenna churches, St. Apollinare Nuovo, especially, there is much to be learnt. "Legitimate mosaic decoration," says an able authority, "like all true architectural decoration, should, in the first place, be made subservient to the architecture." The subjects chosen ought to be simple in design and gradation of colour, while anything approaching pictorial effect should be avoided; the treatment should be broad, and a happy mean between the baldness of the earlier and the florid tendency of the later works taken as a guide. In the friezes, vaults, pendentives, and domes of buildings, mosaic decoration appears to be most happily introduced, as the imperfections of the method become less visible. For walls and pavements mosaic is equally suitable as a coloured incrustation; it becomes, as observed, to the structure it decorates, "bone of its bone," and, by virtue of its intimate connection and durable character, is more desirable as an architectural decoration than either fresco, encaustic, or water-glass. One great advantage in the use of mosaic is the facility with which soot and smoke can be removed by simple washing. Water-glass painting, too, so largely used in Munich, is a great rival of fresco, though its merits have been impugned of late. In this process a soluble alkaline silicate is used as a medium between the colour and substratum. Our object here, however, is to suggest decorative principles rather than technical processes.

Of monumental painting M. Viollet-le-Duc, in his "Dictionnaire Raisonné," speaks with considerable critical acumen. He says: "Harmony in subject painting is always regulated by essentially decorative principles; it changes in quality of tone, but it always remains equally applicable to subject

or ornament. In the 12th century it was absolutely similar to that of Greek painting; backgrounds were kept light, figures and ornaments were put in with full local colour, instead of with what we call demi-tint; reliefs were light, almost white, in their salient parts; modelling was carried out in brown for every tint alike; finishing touches, in light colour upon the dark and sombre parts, and in dark colour upon the light parts, corrected any spottiness in the ensemble. Colours were always broken on broad, light surfaces; gold was used in brilliant parts, such as embroidery and the nimbus of a saint, but rarely as a background." He then proceeds to notice the leading colours, such as yellow ochre, light red, greens, and secondary tints, such as rose-purple, and observes that a brown line divided adjacent colours. In the following century the primaries began to dominate. We do not instance mediæval colouring as in all cases worthy of imitation; but we merely desire to point out that in the purest periods the decorative character was uppermost in the mind of the artist, and that, as art degenerated, the picture became the idea rather than the wall or ceiling. One very fundamental distinction is necessary to be observed, and that is decorative painting is not easel painting: each has its distinct qualities and province. We may here notice some very judicious remarks made by M. Veron upon this point. He says, "Easel painting always seeks more or less to deceive the eye, its aim is to produce the effect of relief upon a flat surface." Again, it must be executed with the intention of being viewed from some one point, but in monumental painting of the best epochs unity of point of view is never attempted. In pictures painted on walls at all elevations, the painter never took account of horizon or effects of perspective, but boldly painted his figures in attitudes proper to the positions. If a horizontal line were assumed there would be only one point of sight, and so soon as the spectator moved from this point the perspective of the whole picture would become false, "all the vanishing lines begin to dance and to give a feeling of sea-sickness to people who viewed them." As the same writer remarks, the system adopted was based on a reasoned-out principle; "it condemns the whole scheme of decoration of a room to appear true to one person alone—he who happens to occupy the right point of view." "What are we to say of that so-called system of decoration which places flat painted ornaments side by side with scenes in which truth of effect, of light and shadow, and of perspective is aimed at? Representations in which reality of appearance is produced by the use of relief are altogether out of concord with flat ornamentation." Monumental painting, therefore, whether it depicts scenes or otherwise, has to deal with plain surfaces, and harmony, not crude colour, nor illusion, should be the aim of the artist who endeavours to unite painting and architecture.

ARTISAN REPORTS ON THE PARIS EXHIBITION.

IT was not by any means a novel idea on the part of the Society of Arts, or of the Royal Commissioners, even of the workmen themselves that a selected body of "Artisan Delegates" should be despatched to the Exhibition at Paris last year, to make their observations upon the various works of industry and more especially the trades which they represented, and to give us the results of their visit in the shape of "Artizan Reports." The experiment has been tried at most of the great Exhibitions, with more or less success, and though the neat pamphlet which presents us with the record of the doings and experiences of the Liverpool Working Men is free from some of the graver faults which have characterised former

productions of this kind, it is almost impossible to escape from the conviction that the gain will be to the men who went to Paris, and not to their brother workmen who may or may not read their reports.

We learn from the introduction that Mr. Forwood, then Mayor of Liverpool, received last year a circular from His Royal Highness the Prince of Wales proposing that steps should be taken to send some skilled workmen to Paris, to see the Exhibition, and report upon the trades they followed. As a consequence of the action inaugurated by the Mayor, subscriptions were received to a considerable amount; and ten men started for Paris—or, at any rate, this number sent in reports. They were:—A bookbinder, a boot and shoemaker, a bread-maker and confectioner, a cabinet-maker, a cooper, a pattern-maker; a gilder, a letterpress-printer, a ropemaker, and a general reporter, who treats of the excursion, and rambles over various topics, from Sanitation to the Electric Light. The General Report leads the van, and describes the hearty welcome which the Liverpool party received from Sir Philip Cunliffe Owen and the many ways in which the genial Secretary of the Royal Commissioners attended to their comforts; for which, by the bye, we find he was presented with a copy of a "resolution drawn up and approved by the men," thanking him and his staff for their many acts of courtesy and kindness. It is not necessary that we should do more than glance at the various reports which follow: we find from the introduction that "each Artisan was requested to devote at least seven days (inclusive of travelling) to an inspection of the Exhibition, and of the manufacturing establishments in the City of Paris, where the special work in which he was interested was carried on." This latter instruction was no doubt excellent in theory, but must have been rather difficult in practice. Indeed, but for the exertions of Sir P. Cunliffe Owen, it would be next to an impossibility for a stranger, of the Artisan class, to obtain admittance to the workshops of a foreign country. We are surprised to find in how many cases our Liverpool friends did, however, actually see the methods pursued in French workshops, and thus obtained an insight into the details of the manufactures, whose results only could be seen in the Exhibition building.

The reports vary greatly in length and completeness; the power of observation rarely goes hand-in-hand with the facility of recording what one has seen; certainly not in the artisan classes of this country. A man may be a first-rate craftsman, but totally unable to tell his fellow workmen the details of the processes in which he is skilled, or to analyse the causes of success and failure in a trade with which he is familiar. It is this defect which is most conspicuous in all the artisan reports which have come under our notice, the want which is so apparent in all of them of a ready power of description. The best report from the Liverpool men is undoubtedly that of the boot and shoemaker, Mr. John Garvey, and nearly equal to it in merit are those of the printer, Mr. Swainson; the cooper, Mr. McStay; and the cabinet-maker, Mr. James. There is in all the reports a strong tendency to stick up for old England, and to preach the doctrine that we have little to fear from foreign competition, or, as the preface neatly puts it, "It will be observed that the reporters generally unite in the testimony that the products of British artisans compare upon the whole favourably with those of other countries." Some reporters put this truism more forcibly. Thus the ropemaker winds up his brief report, "In conclusion, I saw nothing to alter the opinion that has hitherto been held as to Liverpool by foreigners, viz., that we

make the best rope that can be bought in the world. We have, therefore, I think, nothing to fear in the rope-making business from foreign competition." There is no mincing of the matter here, and several of the other delegates are equally confident that we can "lick all creation."

ARCHITECTURAL MOSAIC.

II.—MEDLEVAL MOSAIC.

THE Ancient Mosaic, as we have said, decayed with the decay of the Roman Empire. But the art had left vigorous roots which, under Christian auspices, started into fresh life, and developed new forms and styles, when the arts were again free to enter upon a renewed career. But yet during the period of decadence (say from 220 A.D., onwards) we may trace the existence of two distinct schools, which were connected by so slight a link with the ancient that Dr. Kugler is "almost tempted to believe that historical mosaic painting of the grander style first started into life in the course of the fourth century." These two schools or styles may be distinguished as 1st, The Later Roman; 2nd, The Byzantine. The Later Roman flourished chiefly in Italy, during the fifth and sixth centuries, and decayed during the mediæval troubles of Italy, about the middle of the ninth century. It employed coloured glass tesserae in common with the Byzantine school, but its distinguishing feature was that the design was worked out nearly always on a ground of blue or white. The finest specimens of this style are the churches of Santa Maria Maggiore at Rome, and St. Vitale at Ravenna. The Byzantine style differed from it chiefly in the constant employment of a gold ground for the design. It originated with the artists who doubtless accompanied Constantine from Rome upon the removal of the seat of empire to Constantinople (Byzantium) and who added to the traditions of ancient work, which they carried away with them, many ideas of magnificence and gorgeousness derived from the Oriental taste of their new land. The most glorious specimen of Byzantine mosaic is the Church—now the Mosque—of St. Sophia at Constantinople, built by the great Emperor Justinian upon the close of his Persian campaigns, towards the middle of the sixth century, and adorned with all the spoils of the East. These splendid mosaics are not at present visible, having, where the Turkish conquerors have found it impossible to destroy them without injuring the fabric, been long hidden under thick layers of fanatical Mahometan whitewash. In the year 1848, however, when the Mosque was under repair and the whitewash was temporarily removed, the late Sultan permitted them to be examined, and magnificent drawings of them were made, which were published by M. Salzenberg in a large folio volume, through the liberality of the then Prussian Government. From a technical point of view, these mosaics are remarkable among other things for the presence among them of silver mosaic, the actual existence of which was for a long time very doubtful, although recipes for its manufacture are found in MSS. of artistic processes of the seventh or eighth centuries. They are found in the great groined vaults of one of the galleries of St. Sophia, and their position is worth notice. This vault is constructionally a groin as far as the middle portion, where it becomes a flattish dome, and the artist has cleverly given the idea of its being a groin to a certain extent, by following the intersecting line of the vault with his decorative lines, and then has indicated its termination in a dome form, by the introduction of a central circular ornament; and in this part some of the silver ground mosaic is introduced.

Another interesting technical feature of the mosaics of St. Sophia was observed by M. Salzenberg, by aid of the scaffolding used for the repairs, viz.:—That when the mosaics can only be seen from beneath at an angle exceeding 45 degrees, the pieces are arranged with their upper edges set forward from the wall face in tiers, farther and farther apart, as the angle of vision is increased. By this means the work is saved on much intervening space, and both material and cost economised, in some parts to the extent of two-thirds of the whole. This method also had the advantage of reflecting the light at a better angle to the eye. The pieces of glass usually employed in Byzantine work were of irregular shapes and sizes, and of all colours and tones of colours, and very seldom indeed without gold ground. The execution was always large and coarse and very rarely approached even the "Opus Majus Vermiculatum" in neatness of joint or regularity of bedding, and yet in general effect of gorgeous, luxurious, and yet solemn decoration, they are unapproachable. They often produce even an effect of sublimity, which is due chiefly to the great simplicity of the forms and draperies, and the severely majestic, or grandiose, expression always given to the swarthy visages of the saints and heavenly beings who were their chief subjects. The style, however, was conventional and monotonous in the extreme, and true, natural art under its exclusive influence was impossible. But for many years it was the only pictorial art which was practised or has survived to our day, and it is to Byzantine mosaic we are indebted for the preservation of much of the symbolism, and many details of the ritual, and even of the theology, of the Christians of those early periods. It prevailed extensively all over the East, and at last came back to Italy, influencing all the architecture of that country and its neighbours for at least a thousand years. The Later Roman style having decayed, the Byzantine—or Greek, as they were now called—workmen came into Italy in the early part of the fifth century, and for a period of six hundred years were the principal—nay the exclusive—workers in mosaic everywhere. A chronological list of buildings decorated by them in this interval is given by Lord Lindsay in his "Sketches of the History of Christian Art." In the year 1073 the decoration of St. Mark's, Venice, with mosaics was begun by the "Greek" artists and was continued by them till the 14th century. Their work is estimated to cover a space of 30,000 square feet of the upper wall, vaulted roofs, and cupolas, and are on a gold ground. The mosaics of this building are the grandest and most extensive in the world, being executed by successive artists through several centuries; and form a perfect cyclopædia of the history of the art. For in addition to the work of the Byzantines, they were continued by the Italian artists down to the 16th century, designs being furnished by the greatest artists of the day such as Titian, Tintoretto, Salviati, Sansovino and others. In range of subject the mosaics of St. Mark's have been styled by Mr. Ruskin "the poor man's Bible," and he adds, "a glorious Bible." All the wealth of Venice was expended during six centuries in putting these works together; and in 1610 the Senate of Venice decreed that no ancient mosaic should be removed, whatever its merits or demerits; but where it was in danger of ruin, the design should be carefully copied and the work restored to its original state.

In the middle of the 13th century, the Italians, led by Andrea Tafi, a painter of Florence, emancipated themselves from Greek tutelage in mosaic, and it is remarkable, as Vasari points out, to observe how rapidly Tafi improved when working on his own responsibility at the Church of S. Giovanni, Florence, after having induced a Greek workman of St. Mark's, Venice, to teach him

the details of the art. It appears that his method of working was to mark the cartoon with red outlines on the stucco, and set his squares very deeply into it firmly cementing them also to each other. He had not, however, taken sufficient care to guard against the penetration of damp to the back of his work—one of the most fatal enemies to mosaic—and this defect was afterwards effectually cured by Agnolo Gaddi, who employed as a hydrofuge stucco made of mastic and wax, which has proved effectual to the present day. Among the contemporaries and successors of Andrea Tafi were Jacopo da Turrita, the Gaddi, Giotto and others, and under their influence the art became Italian, and no longer exclusively Greek. The works of these artists forms the third and best style of mediæval, or Christian, mosaic, which for convenience has been called the Romanesque. This style, while still remaining many traditions of the Byzantine school upon which it was founded, is distinguished by greater freedom in the designs, due to the employment of the most eminent artists of the period. Many of the later mosaics of St. Mark's are by artists of this school, but it finds its most complete illustration in the decorations of the dome of St. Peter's at Rome, which were begun by Clement VIII. at the commencement of the 17th century. The decoration of this church, in fact, exercised as great an influence on the progress and development of the Romanesque school as that of St. Mark's had upon the Byzantine. When it was begun, mosaic workers in Rome were scarce, and they were paid at the high rate of four scudi per square palm for coarse mosaic; but this rate of pay soon attracted such an influx of workmen that the price was soon brought down to half a scudo, equal to about half-a-crown of English money. Natural causes operated very much in promoting the cultivation of mosaic in Rome, for the humidity of St. Peter's proved so destructive to oil paintings, that it was found advisable, even in the time of Urban VIII. to substitute mosaic. The study of the art was also stimulated by the constant discovery of fresh ancient examples, and also by the genius and skill of the artists, among whom may be named Muziani, Paolo Rossetti, Marcello Provenza, the Fabio family,—who copied in mosaic some of the works of the great painters, Domenichino, Guercino, and Carlo Maratta,—and Giovanni B. Callandra who died A.D. 1644 and executed the well-known copy of Guido's picture of Michael the Archangel, in one of the chapels of St. Peter's. Callandra also invented a retarding mastic cement, which removed the greatest difficulty in the way of the old methods of fixing the tesserae, enabling the artist to improve and correct his work as he proceeded, and thereby conferred the greatest benefit upon the art. No improvement or change of any importance has taken place since his time until the modern revival. There were, however, two kinds of mosaic, common to all the above styles or schools of mediæval art, namely, (1st) Opus Grecanicum, and (2nd) Opus Alexandrinum. Opus Grecanicum was mainly a system of glass tessellation, executed in grooves cut in white marble to about half an inch in depth. It was generally employed as an inlay in church furniture, shrines, screens, tabernacles, altars, monuments, &c. The patterns were always of the geometrical kind and often very elaborate, the ornamental bands being customarily combined with large slabs of the most precious materials, serpentine, porphyry, pavonazzetto, &c. It was only occasionally used as an adjunct to architecture. The floor of the chapel and the shrine of Edward the Confessor in Westminster Abbey were executed in this kind of work by Italian artists in the time of Henry III. The finest Italian examples are in the cloisters of St. Paul's, the church of St. John

Lateran, the porticos of St. Lorenzo fuori de Mura, Rome, and the Duomo at Civita Castellana. Opus Alexandrinum, which was sometimes called also Opus Grecanicum, was chiefly work in marble tessellation, executed in grooves like that just above described. It formed the ordinary Italian church paving from the period of Constantine down to the 13th century. The patterns were nearly always geometrical, and very much resemble one another throughout Italy and Sicily. It is not usually finished with such great neatness as the Opus Grecanicum. Having lately given in this journal a full description of this style with an account of some fine specimens to be found in England, we will now merely refer the reader to that article.

Opus Alexandrinum work was discovered almost entirely towards the end of the 13th century, being gradually superseded by Florentine Mosaic, which was formed by slices of marble arranged somewhat like the ancient Opus Sectile, that is, with the projections of one piece fitting into the recess of another. It was in this way used at first for conventional patterns and in monochrome only, but afterwards also for pictorial representations. Its progressive development may be traced from the Church of San Miniato and the baptistry at Florence, though the works of Giotto at the Campanile, Brunelleschi at the Duomo, and Orcagna at Or San Michele, to the singular pavement at Siena, where through the wonderful skill of Beccafumi, large, elaborate compositions may be seen, admirably exhibited in light, half-tint, and shadow, by means of the three marbles only. Another kind of mediæval work is known as Volcanic Mosaic. This bears some analogy with the early Florentine, but differs in the materials, which, as the name indicates, are of volcanic origin. It was developed in Naples, Sicily, and Auvergne, where nature affords an abundant supply of the materials. It was used for external decoration, and was remarkable for the depth and contrast of its tints.

ARCHITECTURAL GEOLOGY.—VI. OLD RED SANDSTONE AND DEVONIAN.

THESE two series of rocks are considered by some geologists to belong to one and the same geological period, since they both are found immediately underlying the carboniferous strata which we described in our last article; and there is no doubt that they have many characteristics in common, and from the character of the fossils which we find in them it is probable that some of their beds were formed at the same epoch in the earth's history. From the fact, however, that the Old Red Sandstone is for the most part a freshwater deposit which has been formed in lakes of vast extent, while the rocks of the series termed Devonian are chiefly of marine origin, it has generally been concluded to regard them as separate formations.

The Old Red Sandstone, with the investigation of which the name of Hugh Miller is chiefly associated, is largely developed in several parts of Scotland, which it stretches across in a diagonal direction in three great belts; the southern zone extends from Haddingtonshire into Berwick, skirting the Vale of Tweed, and passing through Roxburgh, Dumfries, and Kirkcudbright. The central zone extends along the east coast from Stonehaven down to Dundee, and along the Tay Valley, westward to Stirling and Callander, fringing the Frith of Clyde as far as Ardrossan. In the northern parts of Scotland it is found, covering a considerable area in Banff, Moray, Ross, and Cromarty, where it juts out into the Moray Frith on both sides, and skirting the north-east coast is developed into lofty prominences at the northern extremity of Caithness. This formation yields a large amount of material

which is useful for building purposes, as flags for paving, limestone for burning into lime, and an unlimited amount of building stone, the products varying according to locality; white, yellow, and sometimes red sandstones being obtained in Fife and Moray and the southern counties; red sandstones and limestone in Perth, Forfar, Kincardine, and Fife; with paving flags in Forfar, and micaceous sandstones in Caithness.

In the South of Scotland good sandstone for building purposes is found in Dumfries, at Eccles and Thornhill; and the red stone quarried at Corsehill, near Annan, on the Solway Firth, has recently been introduced into London as a building material; white and red freestone is obtained in Roxburgh, at Denholm, Hawick, and Jedburgh. In Berwick good building stone is obtained at Coldstream, Churnside, Dumse, Greenlane, and Paxton; and in Haddington at Garwald and Prestonkirk. In Lanark we obtain white, brown, and yellow sandstone at Broomhill, Lanark, Lesmahogow, and Wilsaw, some of which is much used as a building stone in Glasgow and the vicinity. In Ayr a limestone is found at Dalry, brown freestone at Ardrossan and Dalnellington, and a white freestone near Kilwinning. In central Scotland there are numerous quarries in Perth, at Aberfeldy, Auchterarder, Blackford, Blairgowrie, Cupar Angus, Crieff, Errol, Mylnfield, &c., the stone from which is largely used in the local buildings. In Forfar the red colour prevails in the sandstones which are quarried at Arbroath, Brechin, Dundee, Forfar, and Kirrymuir, some of which is employed for buildings in London. There are also quarries of building stone at Stonehaven and Kirkside in Kincardine. In the North the red sandstone is worked for building at Cromarty, Dingwall, Inverness, Munloch, and Tain, near Ruthven, Spynie, Auldearn, and Nairn. In Caithness it is quarried for flagstones in the neighbourhood of Thurso.

In England and Wales the Old Red Sandstone is found covering a more limited area than in Scotland, being chiefly developed in parts of Salop, Gloucester, Hereford, Monmouth, Brecon, Glamorgan, Caernarthen, and Pembroke, where its strata attain a considerable thickness, varying from 4,000 to 10,000 feet. In the upper beds are found red and variegated sandstones; in the middle marly sandstones and flags, with beds of concretionary limestones, called "cornstones"; and in the lower part pale-coloured sandstones and marly beds, with cornstones. In Gloucester the grey sandstone quarried at Lydney was used in building Tortworth Court, the seat of Earl Ducie, and also the Cardiff and Newport docks; that from Coleford is much used for buildings in Gloucester and Bristol; grey building-stone is also quarried at Tortworth and Newnham, and a white stone near Charfield. Herefordshire contains many quarries of the Old Red Sandstone, which is largely developed in that county, building-stone being procured in the neighbourhood of Bromyard, Hereford, Leominster, Kington, Pembridge, Ross, Weobley, and on the borders of Worcestershire, near Malvern. The stone obtained at Chepstow, in Monmouth, was employed in building the Abbey of Tintern; and about Newport is found a red sandstone suited to building purposes.

Devonian is the name given to a series of slaty rocks, grits, sandstones, and limestones, which is chiefly developed over a large portion of North and South Devon and in parts of West Somerset and Cornwall, and in its upper strata closely resembles the Old Red Sandstone. In the northern parts of Devon it covers a large tract of country, extending from Baggy Point on the extreme west to Wiveliscombe in Somerset, while in the south it occupies most of the country bordering on the sea from Dartmouth

east to Plymouth, and over a large portion of Cornwall, from Mount's Bay in the south-west to Tintagel in the north. In the neighbourhood of Barnstaple and Dulverton we find beds of calcareous sandstone, grey slates, and nodular bands of limestone. Beds of red and grey sandstone occur along the north coast about Trentishoe; calcareous slates, with bands of limestone, extending from Ilfracombe to Withycombe and the Quantock Hills in Somerset; while grey and purple slate is quarried at Morteheo on the north-west coast, at Challacombe, and near to Wiveliscombe in Somerset. Beds of hard red and grey sandstone, with slate, are found in the neighbourhood of Dunster, Minehead, Porlock, and Linton. Black and white marbles are obtained from quarries in the neighbourhood of Bridestow, South Tawton, Drewsteigton, Chudley, and Staver-ton. In the south of Devon this formation contains large quantities of limestone in the neighbourhood of Ashburton, Bury Pome-roy, Chudleigh, Ipplepen, Newton Abbot, St. Mary Church, Plymouth, and Torquay, from which are obtained excellent marbles, together with stone for building and paving purposes. Marbles of various shades of grey, with white and yellow veins, and occasionally red marbles, are procured near Plymouth, Pitit Tor, St. Mary Church, Babbacombe and Newton Bushell. At Ipplepen, near Totness, a handsome red marble is obtained in blocks of considerable size; and at Kitley Park the marbles are green and rose-coloured. The chief slate quarries are at Newton Abbott, South Molton, Tavistock, and Totness; slates are also obtained from the quarries in Somerset, about Wiveliscombe and Wellington, which also yield flags and building-stones. In Cornwall the formation is chiefly remarkable for the excellent quality of the slates obtained from it, the best being quarried at Delabole, near Camelford, Tintagel, Liskeard, Callington, Linkinghorn, Mawgan, Bodmin, and Wadebridge; from some of which places good paving stones are also procured.

SILURIAN AND CAMBRIAN ROCKS.

These rocks, which are considered by geologists to be the oldest of the fossiliferous formations, derive their names from the localities in which they are most largely developed in this country; the Silurian being found in large portion of Wales and the English counties bordering thereon, a part of the kingdom formerly occupied by the tribe of ancient Britons known as "Silures," over whom Caractacus reigned as king, who is well-known in history for the brave stand he made against the Roman legions. The Cambrian rocks, which form the base of the Silurian, and were formerly looked upon as belonging to them, but are now separated into a distinct group, are chiefly developed in the north-west of Wales, small patches only being found in other parts of the Principality. The chief characteristic and most valuable product of all these rocks is the slate, which they yield in large quantities, suitable for use as slabs, or for roofing purposes, the quality of this slate being superior to that obtained from any other formation. The slate of these formations is generally termed by geologists "clay slate," to distinguish it from the thin sandstone flags which are found in the coal-measures, and are often used for roofing purposes; clay slate consisting chiefly of clay which has been subjected to enormous pressure, both horizontally and vertically, whereby it has been completely metamorphosed, and a new stratification called "cleavage" introduced, which is often at right angles to the plane to which the beds were originally deposited. It is by means of this cleavage that the quarryman is enabled to split the slate to any required gauge of thickness merely by the use of a hammer and chisel. The action of heat has also destroyed all trace of any

fossils which the clay originally contained. The principal slate quarries of Wales are those in the neighbourhood of Bangor, Conway, Tremadoc, Ffestiniog, Llangollen, Portmadoc, Dolgelly, Barmouth, Montgomery, Denbigh, Llangodog, and Aberystwith.

In the North of England these rocks are developed in Cumberland, Westmoreland, and the adjacent parts of Lancashire, where large quantities of greenish coloured slate is quarried about Ulverstone, Coniston, Cockermouth, Hesketh, Newmarket, Ambleside, Keswick, Windermere, Broughton-in-Furness, Whitehaven, Burnside, Langdale, and Kirby Lonsdale. Flags and building stones are also obtained from most of these quarries.

In the West of England the Silurian rocks are found in the counties of Stafford, Worcester, Gloucester, Salop, Hereford, and Monmouth; sandstone and limestone being procured from them near Dudley, Abberley, Malvern, Walsall, Bilston, and Sedgely. Near Hereford the Woolhope limestone is quarried for building purposes; at Ledbury, Aynestry, and Donnington, an hydraulic cement is made from the limestone, and a good building material obtained from the sandstone; at Downton Castle, in the North of Hereford, a micaceous sandstone is quarried. Limestone and sandstone are obtained at Mayhill in Gloucester, sandstone and flags at Dymock. In Monmouth the flags and limestones are quarried for building purposes in the neighbourhood of Usk, and at Knighton and Presteign, in Radnorshire.

The Silurian rocks of Scotland are less calcareous than those of England and Wales, and consist of a fine-grained clay slate of an inferior quality, together with coarse granular sandstone. This formation ranges across the Southern counties of Scotland, from St. Abbs Head on the east coast, through Berwick, Roxburgh, Peebles, Selkirk, Dumfries, Ayr, and Kirkcudbright, as far as the Mull of Galloway on the West; forming the Southern Highlands and the ranges of the Lammermuir and Pentland hills. In the north we find a thin band along the south-eastern borders of the Grampians, and in Argyre, Ross, and Sutherland. It also occurs in parts of Forfar, Kincairdine, Aberdeen, Banff, Elgin, and Caithness.

The chief slate quarries are those of Ballachulish, in the north of Argyre, near the entrance of the Caledonian Canal. There are also slate quarries in Perth about Glenshee, Criff, Tullybeagles, Benledi, and at Birnam and Dalbeattie, near Dunkeld. Those of Abercainry and Aberfoyle yield sandstone for building as well as slates for roofing. In Forfar slates are obtained at Dundee and Forfar, and limestone at Brechin and Hedderwick. In Aberdeen there are slate quarries at Aboyne, Gartley, and Tronp-hill, and in Banff we find limestone at Keith, Fordyce, and Cullen.

The Cambrian rocks yield the purple slates of the Penrhyn quarries in North Wales, and those in the locality of Llanberis pass; also the slates of Ffestiniog which are shipped at Portmadoc, and those of Machynlleth, Aberdovey, Llangollen, and Barry Island. The quarries of Llanfair and Dorothea west yield green, blue, and red slates; those near Barmouth, purple and green slates, with a sandstone suitable for building. Good building stone and flags are also quarried from the Cambrian rocks about Ffestiniog. At St. David's and Ramsay Island this formation yields different coloured slates, with flags and sandstone for building. In England patches of Cambrian rocks are found at the Longmynd hills and in the neighbourhood of Shrewsbury, where green and purple slate and grit-stone is quarried; and at Charwood Forest, Barrow-in-Soar, and Bardon in Leicester, roofing slates are procured from it. The

Hollybush sandstone, which is quarried near Malvern for building purposes, is considered as belonging to the Cambrian formation.

The rocks of the Silurian formation are of marine origin, and appear to have been deposited in shallow seas, as many of the limestones are formed of old coral reefs.

MR. SEYMOUR HADEN ON ETCHING.—I.

THE first of a course of three lectures on Etching was given by Mr. F. Seymour Haden, F.R.C.S., at the Royal Institution. The lecture was illustrated by a series of etchings by the old masters, shown upon screens. The admirers of the art of etching ought, the lecturer thought, to have a desire to share with others the pleasures which had recently been a sealed book to almost all. He had himself long enjoyed the impulse of raising an art that had been lost, and he wished to have the opportunity of explaining something, that needed explaining, and of putting right what seemed to him to be wrong; those were the incentives, and he trusted would be accepted by his hearers as excuses for his appearance before them that day. It was, perhaps, surprising, that as a man belonging to a scientific profession he should have addressed himself to the elucidation of a scientific point without bringing to bear on it the prejudices which belong to professional habits and modes of thought. A member of his, or, indeed, of any profession, was not under influences conducive to movement of mind, except in the usual groove and by the customary routine, with the necessary result of a limitation of view. It was his wish to look over the sides of the groove of the etching world, and to assist his audience at the same time to understand the origin and *raison d'être* of the art. He referred those wishing to go more fully into the subject than would be possible in three lectures, limited to an hour each, to procure a little book he had written, "Notes about Etching," published by the Fine Arts Society. It was his belief that the art faculty was innate; that it could not be acquired—like the moral and intellectual forces, it might be cultivated if already present in the mind, but could not be created. At the same time this art-faculty might be debased as easily as it might be improved, by wrong examples and teaching. Upon this subject of education by example and precept, he considered that what was called an academical school was bad in its influence upon art. He believed that an academy—any academy—which was established, ostensibly, at all events, for the purpose of subserving the highest objects of art, in reality had no other effect than to cause one artist to resemble another. An academy, like any other guild, was very beneficial to the interests of the artists, but not to those of art. Nor would he attach any greater value to what was called technical superiority, nor to traditional manner than to academical training. Further, minute rendering in artistic work was bad. Elaboration of detail required time in execution, whereas a work of art presupposed an active conception in the mind of the worker as quickly developed. A picture which had taken a year to prepare would probably be a very poor work. The great masters believed that the fire of genius burned very quickly, and acted accordingly. He would not go into what constituted a good drawing, as he had done that in the little book already referred to. All fine art was suggestive, and not imitative; realistic work was thoroughly bad and foreign to the instincts of art. A good drawing was not an exact representation of the object sought to be pictured to the mind; but a collection of lines so laid down as to suggest the object and to give the impression of the great force which it had in nature. If a man could do the latter he could draw; if not, however carefully he might follow the rules laid down in schools, he could not draw. No painter undertook to reproduce the morning mist, for example, but merely to suggest it; the sculptor did not select marble to represent human flesh because of any analogy or resemblance between the substances, but because the material carved allowed of the utmost delicacy of form in portraying the human outlines, while possessing a purity of tone with which flesh could not compare. Amongst artists, the dreamer who wished to express his high conceptions in the tersest manner, employed the point as the tool with which to write; the etcher's needle possessed an in-

eisiveness of character which was shared by no other instrument or process. This thought brought them to the main object of the discourse, the restoration of the etching to its proper place in art, that place which it once occupied, but in which it no longer stood. How was that to be attained? He thought its restoration might be accomplished by a better understanding, both inside and outside the art, as to what painters' etching really was. The first thing was to explain what it was (a thing he thought very few understood), both in theory and practice. The former he would undertake that day, and the latter in the two succeeding lectures. In the first place, he must treat upon the theory and history of the art, and why it was practised. In the second place, he should consider the cause which had displaced etching from its proper position, a cause which he should show was still in operation to prevent its general practice, and in the third place, he would indicate the mode in which that deterrent cause might be got rid of. In the first place, therefore, the history of engraving told us that it was by origin a painter's, and not an engraver's art. The early painters engraved their own works, resorting of course to the use of tools for the purpose, in the hope of making their works more widely known, and so of increasing their artistic fame. There were originally no copyist engravers, nor were there even when the work passed into an art of delving in the copper-plate without lead. Engravers proper did not appear till the depression of art in the period of the Commonwealth. After the death of Charles I., art was stamped out; all the King's pictures were sold, and dispersed over the Continent, and high art disappeared in England quite suddenly. If they took the whole period of engraving on copper, from its development in the fifteenth century to its decline in the nineteenth century, it would be found that it consisted almost entirely of works executed by the burin and graver, and that it might be easily divided into two classes—that of the painter or artist, and that of the copyist. From the moment that it became possible to produce engraved work by the point of the pencil, the burin fell from the hands of the former and higher class of workers, and artists devoted themselves to original etching, while those who still used the burin became mere imitators. It was evident, therefore, that there could, in the nature of things, be no personal antagonism or rivalry between the two classes of engravers and etchers. Notwithstanding the higher character of etching, the etcher was excluded from the ranks of Royal Academicians, while engravers were admitted to equal membership with painters, sculptors, and architects. This action on the part of the Academy constituted a tacit indictment of the etcher, which it was the duty of the etcher to plead to and answer if he could. The reason the old masters etched was simply to extend their reputation, and because, fortunately for art, there were no engravers to do it for them. There was an impression current that etching was not good in which you could see between the lines, and that such an etching had a gridiron effect. But true art consisted in producing the greatest effect with the least effort, and the best artist was he who used the fewest lines to convey his meaning. The works of the best etchers, as could be seen on the screen, contradicted this theory. The right number and character of lines were those in which the artist could best express his own thoughts and peculiar temperament. The art of etching was purely a suggestive one; if this were not the case, it would be realism, and not art; the more detailed the work was in its details, the more opaque and uninteresting was it likely to be. For all that, the doctrine of elaboration was that maintained by the Etching Club. That it was mistaken might be seen from the examples of Rembrandt's etchings exhibited on the screen; the brilliant appearance of the first-proof of one of his works with the effect of the second when it had been touched up was very noteworthy. But he must pass on to the second, and by far the most important, part of the subject, and that was to consider the causes which had been in operation to displace the originality of etching from its proper rank in art, and which were still in existence to prevent its rehabilitation. The period of this debasement of etching might be considered to extend from the establishment of the Commonwealth to the present moment. The low state of art at the former time favoured the

introduction of the copyist engraver, and that agent had, in our own days, enrolled as a co-worker, the dealer in pictures. The present low state of art depended, and was due, almost entirely to the combination of the engraver and the dealer. The way in which the engraver came upon the scene was this. One could imagine him going to the painter, let them say, for example, Vandyke, and saying to him, "What is the use of your doing etchings? There is no art here now, the king is dead, all the great patrons and masters are fled; there is none left who cares for art. What is the use of your etched plates? Nobody understands them, and as for the idea you contemplate in 'Icones,' of portraying a hundred of the most eminent and foremost men, spare yourself the labour and let me do it for you. True, my work is not exactly like yours, but it will be quite good enough for these times." Vandyke, we know, yielded to these arguments; the "Icones" was completed by mere engravers, and thus the art of etching was lost—killed by the same blow that chopped off the head of King Charles. The lecturer showed on the screen the forceful and beautiful character of some of the heads in the "Icones," as etched by Vandyke, notably that of the Earl of Pembroke, and the mode in which they were elaborated and spoiled when the engraver touched them. The work of the etcher fell presently into the hands of Woollett and Sharp and that class of engravers, and subsequently, into a still greater type of workmen, the mezzotinters, many of whose works were so good in their way, that people almost forgot that they were not original. About that time, Hogarth and Turner conceived the idea of engraving their own works. Hogarth could not stand the manner in which his works were engraved, and it was to that determination to become his own engraver that we owe the pleasure which all felt in looking at Hogarth's works. Turner followed the example, and if time had allowed he would have become a great engraver. He etched all his works himself, and in many cases also mezzotinted them. Nothing was more interesting than to examine his work; the little faults and improvements he found in the proofs showed how difficult he found it to be satisfied with the mezzotinters. In face of the fact that three of the greatest artists and etchers, Rembrandt, Hogarth, and Turner, all etched for themselves, because dissatisfied with the engraver's work, it was unnecessary to urge the superiority of etching over engraving. If this were the feeling of artists in the best days of engraving, how much greater must be the difference now that engraving was really bad? The operations of the modern dealer were very characteristic, and directly inimical to the development of etching. The *modus operandi* of the dealer—the ideal representative of that class—was wonderfully clever. He posed himself as the sole medium of negotiation between the *nouveaux riches* of no refinement, but who must follow the prevalent fashion, and the artist; he was shrewd and businesslike, and determined to speculate in art. He, therefore, went to the painter, and asked him the price of his picture. "£500." "Very well, you may raise it to £1,000 on this condition—that you only sell it through me." Then the dealer saw the *nouveau riche*, and told him he must have a picture by So-and-so, and that he would procure one for him at about £1,500. But the dealer operated on a very much larger scale than that by means of the great "steel plate." The dealer went to a different sort of artist, and said, "I must have a picture, one of a kind that will impress the greatest number of people—it had better, therefore, be religious. In order to invest the work with the greater reality, you must go to the East, and you must be away about three years painting it, and after you bring it home we will exhibit the work all over the country. We will engrave it, and take off thousands of impressions from a steel-plate, everyone of which we must call 'proofs.' Now, we will have, say, perhaps, a thousand impressions, all 'proofs before letters,' another thousand 'proofs after letters,' some artist's proofs, proofs on indigo and other paper, at ten, eight, six, and five guineas each, to suit the credulity and pockets of those who have to pay for them, although, as you know, there is not the least difference between the several proofs." The whole transaction between artist, dealer, and engraver would thus reduce itself into a very serious conspiracy. The dealer sought to make himself sole arbiter between the

purshaser of pictures and the artist, and to be the sole judge of art. With these 20,000 or 30,000 issues of "proofs" of steel engravings one might compare the forty or fifty impressions of etched plates. The dealers' influence and power was immensely augmented by the action of the Printers' Association. That was an organisation established for the express purpose of stamping every one of these so-called "proofs" as proofs on payment of a certain fee for each copy, and the stamping of the Association was regarded as evidence that such impressions were proofs. The Association took to itself immense credit for its operations. It would stamp as many proofs as a member liked to take, if he paid the fee, and the purchaser could afterwards point to this stamp upon his copy as proof that it was a proof. It was evident that etching had the utmost difficulty in making a stand against such a custom. It had been proposed to call the present time the Iron Age or the Steam Age, but, in his opinion, a more distinctive name would be that of the "Steel-Plate Age." There was yet another cause for the decline of etching, which it was extremely awkward for him to touch upon, and yet he must do it, as he was there to speak the whole truth. One of the reasons for the non-revival of etching was, undoubtedly, the character of the work executed by the amateur etcher. For twenty years past it had been supposed that anybody could etch, and some very bad work had been done by the amateurs, so bad that the Royal Academy had made it an excuse for the thorough exclusion of etching from its walls. For this he did not blame the Academy so much as the amateurs. The art itself could not, however, be held responsible for the bad work issued under its name. He was extremely sorry for the bad work he had done himself. He should not publish any more etchings; he would advise amateurs generally not to prepare any more, and then the Academy would have no pretext for refusing to admit etchings. He had no ill feeling against the Academy; very many of its members he knew, and respected them as personalities; but the mischief they did in their corporate capacity was immense. For a quarter of a century they had not elected an etcher amongst them, and yet there was one man who ought years ago to have been an Academician—he referred to Samuel Palmer. His etchings were carried as far as it was possible for such works; they were, indeed, much too elaborate for his own taste, but the Etching Club swore by them as the best ever produced; yet the Academy had never recognised him, while they had elected engravers as members. But he must proceed to his third point: the remedy for the debasement and neglect of painters' etching. This lay with the Academy, who ought to exert themselves to revive the art. They might do that very easily—in the first place, by encouraging its use amongst themselves. By so doing there would at once be an end of the amateur, who very naturally was hateful to the Academician. If only educated painters would etch, Mr. Haden declared he would himself etch no more, and he believed every other amateur etcher would come to the same conclusion. He thought it would also be a good thing for the Academy to exhibit the works of the Etching Club—a body which certainly did nothing, or scarcely anything, for etching as an art, and which consisted entirely of Academicians. Then they ought to give etchings a proper place on their walls, and not hang pell-mell those admitted, as was now the case. Why should not etchings have as good and distinct a place as paintings, architectural works, or sculpture? The Academy might arrange for a winter exhibition of etchings in a similar manner to that of the Old Masters—which, by the way, was entirely owing to the suggestion of the Burlington Fine Arts Club. That exhibition came about in this way. When the British Institution of Painters broke up (for want of funds, so it was said), the Burlington Fine Arts Club of Connoisseurs endeavoured to carry on the winter exhibitions of the Institution, and negotiations were opened with the Academy for the use of their galleries for the purpose of showing works by the Old Masters during the six months those rooms were previously closed. The proposal was accepted by the Council of the Academy, and Sir Francis Grant met the Burlington Club and arranged everything. When the scheme came before the general body of members they refused to confirm the arrangement, and it fell through. The club

then called on the Academy to carry out a similar plan themselves, and this had been done. Returning to the remedies for the present condition of etching, he might add there was one more important thing the Academy might yet do, namely, to elect into their body some original etchers, and if they asked him where to begin, he would point to Samuel Palmer. By recognising etchers as artists the Academy would be doing something towards restoring and revivifying this interesting and beautiful art.

MEDIEVAL PARIS.*

(Continued from page 297.)

ON the summit of the hill on the south side of the City of Paris, Clovis, the first king of the Franks, on his conversion to Christianity, founded a basilica dedicated to the Apostles SS. Peter and Paul. Clotilda completed it, and Clovis was here interred. St. Geneviève, the patron saint of Paris, was here interred, and, from the miracles done at her tomb in the ninth century, the church received her name instead of its former one. But that church has entirely disappeared. The Rue Clovis passes over the exact site of the church, but the tower, which was on the south side, has escaped. In the second court of the Ecole des Beaux Arts are preserved the capitals of the columns of the nave. It stood in the immediate proximity of the parish church of St. Etienne de Mont. It possessed a nave with aisles, no transepts, an apsidal choir with radiating chapels, the most eastern being square; it was almost entirely rebuilt in the thirteenth century, but the capitals of the nave before referred to are evidently earlier. The nave and aisles seem to have been covered with one roof. Of the Abbey buildings large portions still exist. Worked into the modern Lycée the three courts still exist—the chapter house and refectory are comparatively perfect. The church was proposed to have been removed in Louis XV.'s time, when the enormous new church of St. Geneviève was built a little to the west of the old, which is sometimes called the Pantheon, but was not finally destroyed until about 1804. The very beautiful twelfth century effigy of Clovis, has been removed to St. Denis. The shrine of St. Geneviève, the most sumptuous in Paris, and often carried in procession round Paris to avert some threatened misfortune, was melted and broken up in 1793, but did not realise the amount expected to the Revolutionary cash-box. Of the Abbey of St. Victor, close to Halle aux Vins, no vestige now remains. It had been rebuilt in the time of François I., and must have exceeded in size and magnificence the Church of St. Eustache, which it probably resembled. Its stained glass windows were the most splendid in Paris, and its treasury rivalled St. Denis in richness. Here were preserved the hair shirt, comb, gloves, and coif of St. Thomas à Becket. In a very fine bird's-eye view of Paris preserved in the British Museum, and for the time when made singularly accurate, this noble abbey, with its spires, forms a very striking object in the south-east quarter of the left bank. The Grey Friars, or, as they are called in France, the Cordeliers, had a monastery on the south side, Rue Pascal, outside the walls. The church has been demolished, but there are remains of the buildings in the modern hospital. The Abbey of St. Antony has entirely disappeared, but has given its name to that quarter of Paris, the Faubourg St. Antoine. The best preserved of all these monastic institutions is that of the Priory of St. Martin-in-the-Fields, originally outside the walls, but afterwards included in the new extension of the city, by Charles V. It is certainly well worth a visit from all students in architecture. The church and monastic buildings are now the Museum of Arts and Trades. The refectory is used as a library, and the nave partitioned off; the choir was full of agricultural and other machines when I last saw it in October. The nave is without aisles, of immense width, with an arched timber roof and windows very high up in the walls. The choir is earlier, of a solemn Romanesque character, apsidal, of seven bays, with ambulatory and radiating chapels. This part of the church is not in the best of repair, and it is rather difficult to gain admittance, being used as store sheds. The most eastern chapel is of a

very unusual plan, reminding one something of the ace of clubs. The chief glory is the noble refectory, now used as a library; it is divided down the centre by a range of very slender columns, and has in its north wall a pulpit-like baulcon. The proportions of this building are singularly beautiful; but, like the nave of the adjoining church, has been so plentifully bedizened with colour that a great portion of its architectural interest has gone. Most of the Priory buildings remain, but have been so built in and altered that it is difficult to recognise them. The cloisters here were the most beautiful in Paris, but these, with the Lady Chapel, chapter house, and archive tower, had been rebuilt by the monks at the end of the seventeenth century. The abbey was founded by Henry I. in 1060, in honour of St. Martin. The refectory and the Lady Chapel are said to have been designed by Pierre de Montreuil. Notre Dame des Champs was a very ancient priory church, which had belonged to the Benedictines from the eighth century, but was ceded by them to the Carmelites in 1604. It was a spacious church of the twelfth century, under which extended a vast crypt. It was outside the walls in the Rue d'Enfer, and was utterly destroyed at the Revolution. The Order of Mount Carmel have since returned to the site, and fixed their abode on it. The Convent of the Jacobins was also on the south side between the gates of St. Michael and St. James. Their church was built for them by St. Louis, and, like most of the churches of this order, consisted of two parallel naves; there was one peculiarity connected with this convent—their refectory and "parlour" projected through the city wall, and formed externally, as seen from the fosse, a square embattled tower. Most of these churches of the various orders were exceedingly rich in tombs of the noble and illustrious dead; many of the effigies have been preserved, and taken to St. Denis—they formed quite a school of art of French sculpture from the twelfth to the eighteenth centuries. The Knights Templars had a splendid preceptory, rivaling the Chateau of the Louvre in its military aspect of crenellated walls and towers, and its immense central keep or donjon. After the suppression of this Order their buildings passed into the possession of the Knights of St. John of Jerusalem, as in England. Their church was like all those belonging to this Order, circular as to the nave, with a long choir. It was not equal in beauty to our London example, although it might have been larger. It was destroyed in 1805, and the last portions of this once famous edifice were removed in 1853. The Commandery of St. John of Jerusalem, now entirely demolished, was on the opposite side of the city, and was not inferior in beauty to that of the Templars. Their Church, called St. John Lateran, was close to the Hôtel de Clugny. Its barn, in two divisions, divided by columns and beautifully vaulted, was removed in 1854. The tower of the Grand Commander of the Order was in a very perfect state until then, and every effort was made to save it, but without success. Some fragments have been preserved in the Musée de Clugny.

In that small space comprised in the island of the city, not counting the Cathedral, a monastery of the Barnabites, or La Sainte Chapelle, there were no less than seventeen churches, all of which have now disappeared, only leaving very rare traces in some cases behind. The Ile de Cité was then densely populated. The streets were exceedingly narrow, and the very bridges were thronged with houses even in the Middle Ages, immensely lofty, and inhabited by many families—a characteristic of Paris to this day. Gone are the churches of St. Denis du Pas, St. Denis de la Chartre, St. Christopher, St. Geneviève des Ardents, St. Pierre aux Boufs, St. Laundry, St. Croix, St. Symphonien, St. Pierre des Arcs, St. Martial, St. Michel, Jean le Rond, St. Aignan, St. Barthélémy, St. Germain, le Ilieux, La Madeleine, and I believe quite recently what was left of the churches of the Barnabites—St. Eloy and St. Marino. The Cathedral and La Sainte Chapelle are the only existing religious edifices left on the island. St. Jean le Rond occupied a very similar position to the Cathedral, as the Church of St. Gregory to Old St. Paul's, or as St. Margret's, Westminster, does to the Abbey; it nearly touched the north-west tower. All these churches had been rebuilt in the twelfth and thirteenth centuries. Surrounded by the modern buildings of the Hotel

Dien is the very beautiful twelfth century Church of St. Julien le Pauvre, difficult now of access, as it is used as the private chapel of the hospital, but no pains should be spared by the lovers of sacred architecture to see this little gem*. Reference has been made before to the frequency of the change of dedication in Paris. The St. Julian, to whom this church is dedicated, was St. Julian the Martyr, but towards the end of the twelfth century another St. Julian the Confessor, Bishop of Mans, called from his wonderful charity St. Julian the Poor, was substituted. The nave, now of six bays, was almost rebuilt in 1675, and was then shorn of two bays at the west end to enlarge the courtyard. A chancel arch, supported on clustered columns, divides it from the choir, which is entirely, with its chapels, of the work of the twelfth century. It is apsidal in plan, with two ranges of windows in the apse, the lower richly moulded with clustered shafts, and the upper plainly splayed; the first portion of the choir is of two bays, with sexpartite vaulting in each bay. In the clerestory is a coupled lancet window, with internal columns and arches. The capitals of the cylindrical columns supporting these bays and the carving throughout is of the most masculine and vigorous type, similar in character to the choir of St. Germain des Prés and Notre Dame. In the International Exhibition last year there was illustrated a project of rebuilding the nave as it was supposed to be formerly. One has such a wholesome dread of restoration, as understood by our neighbours across the Channel, that one would prefer the process being altogether dispensed with in this case. Another large parish church is close by, St. Severin. The existing ancient churches of Paris are all very late in style; their chief glory is their old stained glass, which exists in most of them. Another point deserving of attention in them all is their clever planning; no site was too difficult or too irregular. St. Severin was almost entirely rebuilt during the fifteenth and sixteenth centuries; the three last bays of the nave at west end are earlier, and also the lower part of the tower which is at the north-west angle. When the Church of St. Pierre aux Boeufs was destroyed, one of the doorways was brought here, and now serves as the west door; the date is about the first half of the thirteenth century. The plan consists of a nave and choir of the same internal height, but externally the roof of the choir is higher, double aisles and an external range of chapels. Attempts were made to give a Classic character to the arches and columns in the reign of Henry IV.; it is vaulted throughout. The stained glass here is very fine, and deserves close attention. Opposite to the eastern façade of the Louvre is the fine church, formerly collegiate of St. Germain l'Auxerrois, not named after St. Germain of Paris, but St. Germain of Auxerre; it formerly held first rank after the cathedral, and was most richly endowed. In plan it is cruciform, but the transepts do not project beyond the double range of aisles; in length it is 240 French feet by 120 feet wide. The nave has only four bays; the choir the same, and seven in the apse. The tower at the south-east angle is the earliest part of the fabric, then follow the central portion of the west door, and the remainder dates from the fifteenth to the sixteenth centuries; but, as at St. Severin, attempts were made to alter its pointed arches and clustered columns to the fashionable style of the seventeenth century. There formerly existed in this church a very beautiful choir-screen or rood-loft, designed by Pierre Lesceot, and carved by Jean Gonjon; it was destroyed in 1744, and some of the fragments are preserved in the Louvre. There is some exquisite old glass in the rose windows and clerestory windows of the transepts. The modern glass, filling nearly all the lower windows, is of the worst description. M. Lassus was the architect employed in the general restoration which this church has undergone. The signal for the fatal massacre of St. Bartholomew was given from the belfry of it. It existed in A.D. 886, for it was pillaged and burned by the Normans. It was then called St. Germain le Rond. SS. Len and Giles, in the Rue St. Denis, is another old church of the same style—Late Flamboyant. St. Nicholas des Champs, close to the Priory of St. Martin, is curious from the mixture of styles, and is singularly imposing from its immense size and

* A paper read before the Architectural Association, on March 14, 1879, by George H. Birch, A.R.I.B.A.

* See illustrations, drawn by Mr. W. S. Weatherley, in the BUILDING NEWS of the 14th inst.

height, and is of the usual plan, without transepts. St. Laurent is similar, again. The famous architect, Lepanto, remodelled the church in the prevailing fashion of his time; but the keystones of the vault are worthy of attention. St. Mercy, in the south-east district, should be visited, for, although very late in style (it having been rebuilt in 1520 and finished in 1640), it still is in the Gothic style. It is a large cruciform church—a nave of five bays, a choir of three, and seven bays in the apse; there are two aisles on the south side of the nave, only one on the north, but both have chapels. Two architects of the name of Slodtz, in the reign of Louis XV., beautified it in the style of that age. Here the stained glass is very fine, but sadly fragmentary; a portion of one window has been removed to make good another. St. Gervais, so conspicuous an object, looking eastwards towards the Ile de Cité and the Hôtel de Ville, is an imposing structure from its height and size. St. Modard is remarkable for its continuous mouldings and curiously carved keystone. I have left the churches of St. Eustache and St. Etienne de Mont for the last, for these two churches are certainly the most beautiful of all the parish churches just described. In St. Eustache the Old Pointed style has died out, but has imparted in a most remarkable manner its characteristics of plan, arrangement, vaulting, &c., on a building which is really Classic in detail. In St. Etienne the Pointed style still prevails as far as the arches, which rest on cylindrical piers, the mouldings dying into them. The axis of the nave and choir here are not parallel. Between the nave and choir is a wonderful architectural *tour de force* in the shape of a jube or rood-loft with winding staircases, and the stained glass is the finest in Paris. Both here and at St. Eustache there is a curious arrangement of clerestorial aisles, worthy of a study to those who have to build town churches. St. Eustache is the largest church in Paris after the cathedral, and is certainly very beautiful. No interior surpasses it in dignity; debased and bad as the detail may be, yet the effect is dignified in the extreme; it is an interior which one can never forget. Some ancient mural paintings of the Renaissance have been discovered in one of the chapels; the west front is still incomplete. Passing along the Rue de Rivoli towards the city, the tower of St. Jacques de la Boucherie forms a very prominent object. The church to which this magnificent tower was attached has entirely disappeared; the plan was very irregular, it had been rebuilt in the time of François I., having been completed 1522, and was destroyed 1797, the tower being preserved for a shot tower, but the image of St. James, which terminated one of the pinnacles, was precipitated to the ground. The steeple was purchased by the city for 250,000 francs, and carefully restored, and forms as striking an object in modern Paris as it did in mediæval Paris. Behind the Hôtel de Ville formerly stood a very large and fine church, St. Jean en Greve; it had two fine western towers, one surmounted by a spire. The extension of the Hôtel de Ville now occupies this site. Of the Church of the Holy Innocents and its famous cemetery nothing now remains; it was on the west side of the Rue St. Denis. There are a number of old views of this fearful cemetery surrounded by a sort of cloister. In the centre was a pulpit something like Paul's Cross, and several stone crosses marking separate places of sepulture for communities. The upper parts of the cloisters in the roofs were used for charnel houses, and the old prints show these literally packed with bones and skulls, of which a very liberal supply lay scattered about in the inclosure. It had its fosse commune, in which coffins were stacked, only separated by a sprinkling of soil. On the walls of the cloister was painted the Dance of Death, and over the portal of the church the legend of the three dead and the three living. This cemetery of the Church of the Holy Innocents must have been a perfect Golgotha, yet the surrounding arcades, all damp and humid as they were, were filled with the stalls of linen-drappers, dressmakers, printers, and public scribes. The Church of St. Paul, near the Bastille, has entirely disappeared; St. Honoré has left a name only behind; and on the left bank St. André des Arcs, St. Benoît, St. Come, St. Etienne des Gres, and St. Marcel, have all gone.

In closing this account of the parish churches, one cannot help forming a comparison between

them and our London churches. The enormous size of these Parisian examples strike one with astonishment, but it must be remembered that mediæval Paris was very densely populated. Each house teemed with life from "cave" to "grenier," from cellar to loft. Separate dwellings for each family have always been the rule in London. Another feature is the enormous quantity of old stained glass still left in the churches. Paris never felt the fury of the iconoclasts, as did some other parts of France. The period of havoc and destruction was the end of the 18th century, and considering the fearful excesses of that time, it is surprising that Paris should still contain so much. The ancient Hôtel de Ville occupied the same position as the present; the centre portion of the west façade was then represented by three gables with traceried windows flanked by two turrets, with spires and vanes, and was supported on the ground floor by stone pillars; it was more generally known as the House of the Pillars than as the Hôtel de Ville. A great part of the ancient palace on the Ile de Cité still exists, although masked by modern buildings of the principal Law Courts of France. The chief gem of this palace was the chapel, happily still existing, and known as La Sainte Chapelle, from the extreme sanctity of the relics purchased from Baldwin, Emperor of Constantinople, by St. Louis, and here preserved. The principal relics were the Crown of Thorns and portions of the true Cross. The chapel is of two stories, for the undercroft, like that of St. Stephen's at Westminster, is level with the ground—not beneath it. It is apsidal in plan, without aisles. There are, first, four compartments, each filled with superb 4-light traceried windows and boldly-projecting buttresses; then an apse divided into seven compartments, with 2-light windows, vaulted throughout in each story, and externally surmounted by a high-pitched leaden roof and central *flèche* of carved oak and leadwork. If one would want an example of perfection in architecture of the Middle Ages we should find it here, for in this building the subtle beauties of proportion, scientific skill in construction, harmony of parts, and splendour in decoration, are as distinct witnesses of that perfection in those days as the Parthenon of the days of Pericles and Phidias. Facing the quay at the corner of the Rue de la Barillerie is the ancient Clock Tower of the palace, and continuing westward from that are several old walls and towers, especially that known as the Conciergerie, where Marie Antoinette was imprisoned prior to her death. The immense hall, called the Salle des Pas Perdus, lately burnt by the Communists, was formed within the ancient walls of the great hall. Unlike Westminster, to which it bore some resemblance in other respects, it was divided by a range of columns down the centre. At one end, corresponding to the dais, was the table of white marble where the King formerly dined, surrounded with the great vassals of the Crown; and at the other was an altar, erected by that most miserable of monarchs, Louis XI. The palace covered a very large extent of ground, and in the façade facing the Rue de la Barillerie was the parish church of St. Michael of the Palace. Close adjoining to the Sainte Chapelle was another beautiful little building, destroyed in the fire of 1610; it served as sacristies and muniment rooms.

During the Middle Ages the colleges of Paris formed a very important quarter; they have now, with the exception of the Sorbonne, nearly all gone; a few remain diverted to other uses. The names of the most famous of these colleges were those of the Sorbonne, Narbonne, Payeux, Siez, Harcourt, Bernardina, which had a particularly fine church founded by Stephen of Lexington, an Englishman; a portion of the buildings exist, used as a fire brigade station. The College of Cluny had been designed by Pierre de Montreuil, and would have vied with the finest at Oxford or Cambridge; traces remain, and some tombs are in the Musée de Cluny. The College of Beauvais preserves its chapel, a very beautiful model for a college chapel, now desecrated; there were many others of less renown. Of the Palace of St. Paul nothing remains; and of the many splendid palaces or hotels of the nobility only the Hôtel de Cluny and a portion of the Hôtel de Sens, and a fine square tower belonging to the Hôtel de Bourgogne. One of the finest of these, the Hôtel de la Trémouille, has only disappeared within these few years. The Mairie of the Fourth Arron-

dissement occupies a portion of an hotel formerly belonging to the captain of the watch. In the Hôtel de Cluny, that most perfectly preserved of all these ancient buildings, the eye rests on Roman, Gaulish, Merovingian, and Carolingian relics discovered from time to time. Antiquities of Norman and early Mediæval times are strewn around. Every age has left its mark behind; and the student in architecture and ecclesiology has no difficult task in tracing the progressive history of Paris from age to age, perhaps with regret for that which is lost, not by the decay of time, but by the violence of those paroxysms of fanatical fury which have so often disfigured the face of fair Lutetia.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

BRITISH ARCHÆOLOGICAL ASSOCIATION.—The sixth meeting was held last Wednesday week, Mr. H. Syer Cuming, F.S.A. (Scot.), in the chair. It was announced by Mr. G. Wright, F.S.A., that the council had accepted the invitation of the mayor and corporation of Great Yarmouth to hold the congress of the year at that town. Visits would be paid to Burgh, Caistor, Blickling, Hail, Dunwich, and other places of interest in the locality, closing at Norwich. Mr. Loftus Brock, F.S.A., exhibited a German glass apostle cup, and several relics of old London from recent excavations, including a silver bottle which had been turned in a lathe in its fabrication. Mr. Earle Way described similar excavations in Southwark, and produced a large collection of Roman articles found in them. The Rev. S. M. Mayhew reported the discovery of some remarkable Roman remains which have just been brought to light by the new drainage works at Lincoln. Seven brick bases on pedestals were found exactly opposite the building discovered last year, and supposed to be the prætorium. He ventured to conjecture that they were for placing upon them the sacred standards of the legion quartered in the city. They were 4ft. 6in. high and 2ft. broad, and have been demolished. A good tessellated pavement has been found near the Exchequer-gate, and elsewhere traces of the ancient sewers of large size and capacity have been met with. The first paper was on "Ancient Thimbles," by the Chairman. After referring to statements made that these articles were of recent date he adduced evidence to show that they were well known to the Romans. The earliest examples, however, in this county and North Europe appear to have been of leather, one of that material being shown. It was in use in County Cork as late as 1820. A large number of examples of brass, dating from 1500, were exhibited. They were mostly found in London, and some of the 17th century have inscriptions. Several ladies who were present produced other examples of high workmanship and finish. The second paper was by the Rev. Prebendary Searth, F.S.A., read by Mr. W. de Grey Birch, F.R.S.L., and was descriptive of a Roman sepulchral inscription recently found at Bath, where several remarkable discoveries have been made in course of the drainage work.

SCHOOLS OF ART.

CAMBRIDGE.—The annual meeting and distribution of prizes in connection with this school took place on Tuesday week, under the presidency of Prof. Sidney Colvin. The report showed a slight decrease in the number of students, which was now 148. A life class had been commenced and had proved successful. In the second grade examination of fifty-four students who presented themselves, twenty-seven passed and eight obtained prizes, and in the third grade five obtained prizes and fifty-seven artisans obtained payments for the school. Mr. Beresford Hope delivered an address on the art and value of drawing.

The water supply of Preston has been seriously contaminated during its passage through open conduits near the reservoir, and the Town Council have decided to replace these by stone pipes from the Grimsargh reservoirs to Alston, at an estimated cost of £2,855.

A stained-glass window, designed and executed by Messrs. Lavers, Barrard, and Westlake, of London, has just been placed in the church of St. Peter, Battlesden. It is in the Perpendicular style, and consists of six lights, filled with scenes in the life of Our Lord.

THE BRISTOL UNIVERSITY COLLEGE.—WALL PAPER DECORATIONS.—SKETCHES FROM AMIENS CATHEDRAL.—VILLAS NEAR LEICESTER.

OUR LITHOGRAPHIC ILLUSTRATIONS.

UNIVERSITY COLLEGE, BRISTOL.

THE design we show in this week's number is one of two submitted by Mr. Stuart Colman, of Bristol, in a limited competition, just now decided. The council, desiring as much of the foreground as possible to be left for a future building of somewhat more expensive character, at the same time wish that the architectural character of the present building should not be neglected. The central block only, therefore, in each of Mr. Colman's designs is the part proposed by him for actual execution. In both designs the various departments, such as literature, science, engineering, physics, and chemistry, are so grouped that they are each readily reached from the central entrance. There is also ready access from the women's entrance, and from the physical and engineering group. The chemical department is behind the main building, and directly opposite the central entrance, from which it is cut off by an independent staircase. The medical school, suggested on the S.W. side, would communicate with the main buildings through an arcade or cloisters. The women's entrance and staircase is on the side farthest removed from the medical school; so that the women can enter the lecture-rooms and laboratories from their own part of the building without encountering the men; and thus an almost complete separation of the sexes is secured. In the three-story design which we publish to-day, the central entrance gives access upwards to the main ground-floor and downwards to that of the physical and engineering departments. The large lecture-room is on the left of the entrance on the main floor, and on the right are the rooms for the secretary and for male students. On the opposite side of the large lecture-room, on the terrace-level, are the women's entrance staircase and cloak-rooms, and their reading-room. The smaller lecture-rooms are on the upper floor. On the entresol-floor are grouped the principal's room, the professor's rooms, and the council chamber. The author's estimates are £11,600 for the two-story building, and £11,020 for the three-story building, fairly worked out at 6d. a footcube. We have reproduced the other design for publication as soon as space will permit, because we think it possessed of considerable originality and suggestive design.

WALL PAPER DECORATIONS.

Two or three weeks since we published a double-page plate illustrating the Gold Medal Designs by Messrs. Talbot and Crane, from the Paris

Exhibition, and to-day we give two more examples of wall-paper decorations, also manufactured by Messrs. Jeffrey and Co., of Essex-road, Islington. The wallflower design is by Mr. Walter Crane, and is intended for sitting-rooms chiefly, though it has been found suitable for staircases, or for dados to small entrance-halls, such as those on the Bedford-park Estate, where this paper is being used in this way with considerable effect. The frieze is bright in colour, and well-chosen for its position, the foliage being based upon the almond blossom, with swallows at regular intervals, giving a slight geometrical effect to an otherwise rather naturalistic design. The staircase wall-paper to the right of our lithographic plate is an attempt to solve what is rather a difficult problem in wall paper decorations, especially in cases where the staircases are of cramped proportions and quick rise. Mr. Brightwen Binyon is the author of the frieze and dado decorations here shown, the filling-in being from the design of Mr. A. F. Brophy. The dado is so arranged that while it can be used for ordinary rooms or halls, yet by simply cutting through the stem of the double panel it can be used for the rake of almost any staircase.

CARVED WOOD PANELS, AMIENS CATHEDRAL.

CONTINUING our series of sketches by members of the Royal Architectural Sketching Club, we publish to-day another sheet of pen-and-ink drawings, by Mr. T. Frederick Pennington, finished on the spot from the casts or originals in the museum. These examples are both well chosen and well drawn. The museum is particularly rich in examples of wood-carvings, both from examples at home and abroad. Members of the Club will next meet at the museum, on Wednesday, April 2nd, at 6 o'clock, when Mr. J. P. Seddon has promised to attend and look over the drawings submitted on the occasion, and the usual visitor will also be present.

VILLAS NEAR LEICESTER.

THESE two houses near Leicester were designed to combine modern requirements with the simplicity and purity of English domestic work (17th century). The cost is about £2,400. The architect is Mr. T. H. Baker, 15, Hotel-street, Leicester.

THE NEW PREMISES OF THE CHRISTIAN KNOWLEDGE SOCIETY.

WE recently alluded to some conspicuous buildings in Northumberland-avenue, and noticed their progress. One structure at the corner of the Avenue and a cross-road leading to Scotland-yard is intended for the new premises of the Christian Knowledge Society. The building in question has been roofed in and so far completed externally as to permit us to say something more definite of the design, and we take the opportunity of a visit to the building made by the Architectural Association last Saturday, of describing briefly the arrangements. The ground plot forms an elongated segment facing the Scotland-yard approach, which is curved, the main frontage being partly towards it and partly facing the Avenue, the corner of which is rounded. Mr. J. Gibson, the architect, has of course designed his principal façades to face the avenue, and this portion of the building will be used as retail shop and offices; the other end of the building being appropriated as a wholesale shop and warehouse. Entering by the main doorway in the circular corner we come to a large retail shop, forming the eastern and angular portion of the building, and lighted by large windows on both fronts. A gallery on iron cantilevers will surround this apartment, which is of lofty proportions. Passing through it on the left is a private entrance with stone staircase, with messenger's room, superintendent's office, &c., in front; behind there is a long narrow room called the "grant department." This portion of the building forms the central division of the block between the circular corner and the warehouse at the western side. The latter is a large area, rather wedge-shape in plan, devoted on the ground floor to wholesale business. It is divided by massive cast-iron pillars into bays, the floors above being of timber resting on wrought iron girders. Near the centre is a large well-hole and stairs which continues from top to bottom of the warehouse and gives access to the several superposed floors, six in all, besides the basement. The well-hole is surrounded by iron

pillars of several tiers. A lift also will traverse the warehouse floors. The solidity of the circular iron pillars strikes us in this part, but the loads on the floors will be very great. In the basement there are packing-rooms, two strong-rooms, besides urinals and lavatories for the use of the men employed in this department. We notice that the building is divided into three blocks by party-walls and iron doors, agreeably to the rule for the limitation of areas in the Metropolitan Building Act. Ascending the staircase, we reach a mezzanine floor, set apart for a tract office and accountant's room, with lavatory and w.c. On the first floor, over the retail shop, is a committee-room, a secretary's office, and a board-room, the latter being a long apartment with rounded end, lighted from the Avenue front and at end, and in communication with the secretary's offices. A circular iron staircase for private use is provided in this part. The board-room is well-lighted, but quite plain in its finishings; above are the editorial offices, the upper floors being chiefly residential. No attempt at decoration has yet been made; all the rooms are plainly finished with plaster, and are yet in a rough state. The materials used and the workmanship appear to be of the best and most durable kind; the landings and stairs are of stone (Yorkshire), and the walls of stock with gault bricks for facings. The façades are faced with Portland stone, and the quality of the mason's work is excellent in appearance. The façade is of two orders and an attic. The lower or basement order is Doric, rusticated in channels, over which is an entablature of rather unusual design. The upper members or the corona and cymatium of the cornice are omitted, there being instead a flat band-like member of very slight projection, while below this is a frieze with a guilloche ornament of convex contour. The general effect is perhaps rather flat, and sticklers for orthodox classicism will find fault probably with Mr. Gibson's innovation. The main order is a kind of Composite, and here the architect has certainly exceeded the conventional proportion for height of shaft, which looks somewhat attenuated. This order is continued round the façade, and comprises two stories. On each front the bays are arched in the attic, but in the rounded corner a straight entablature runs through; a pleasing variation is thus produced, the arched side recesses and the intercolumnar spaces in the corner being filled with windows of different design. Above the attic story is a deep-coved cornice, with trusses above the pilasters; the cove itself is carved with a diapered pattern, and a similar kind of relief is carved in the hollows of the semi-circular arched windows in the attic. In the spandrels are wreaths carved in relief. The roof is rather high-pitched, with dormer windows, pedimented, over those below. The effect of the building as we approach it from the Embankment is dignified and bold; the Palladian style of Italian adopted well disguises the parts otherwise small and unimportant, and the treatment is removed from that commonplace kind of Italian we have had so much of. It is to be regretted the columnar arrangement could not have been carried throughout the whole front, instead of the rather unpleasant break which occurs between the offices and warehouse portions of the façade, the horizontal members and windows of which latter part, we observe, do not align agreeably with the corner portion. The contractors of the building are Messrs. Cubitt and Co., who have also carried out the ironwork. Mr. Hankins has acted as foreman to the builders, and Mr. Mason as clerk of works under the architect, Mr. John Gibson.

At Lambeth Police-court, on Thursday in last week, Mr. Arthur Timewell, the late proprietor of the Marble Rink, Clapham-road, was summoned by the Metropolitan Board of Works for non-compliance with a notice as to the construction of the rink. It appeared that the building was erected under a two years' licence as a temporary structure, and that it was not built in accordance with the requirements of Mr. Parsons, the district surveyor, and he had now called on the defendant either to alter it as required, or to pull it down. The point was raised, whether after a licence was granted, the rink could be regarded as "in course of erection" within the meaning of the Metropolitan Building Act, and Mr. Ellison, after consideration, held that the summons must be dismissed.

A new Wesleyan chapel has been opened at Scruton, near Bedale. It seats 75 persons, and cost £320.

AMIENS CATHEDRAL.

CARVED WOOD PANELS.

*I think Birmingham
Nov. 78.*

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

AN ordinary meeting of the Institute was held on Monday evening, the President, Mr. Charles Barry, in the chair. The following gentlemen were elected to membership:—As Fellow: William Oakley, Associate, 29, Charles-street, St. James's, S.W. As Associates: Alfred Jackson Martin, Darlington; Sydney Robert James Smith, 94, Lansdowne-road, South Lambeth, S.W.; Frederick Edward Fellows Bailey, Lichfield-street, Walsall; and Alexander Henry Kersey, 65, Moorgate-street, E.C. Prof. Martin Gropius, Government Architect, Berlin, was elected by show of hands as an honorary and corresponding member.

ARCHITECTURAL FOLIAGE.

Mr. JAMES K. COLLING read a paper on this subject. Sculptured foliage, when well and successfully engrafted upon architecture, never fails, said the author, to greatly enhance its richness and elegance. This is fully in accordance with all the most perfect developments of architecture as seen in the best works which have been handed down to us from the earliest ages, whether they are the remains left us by the Egyptians, the Greeks, the Goths, or any others. Unfortunately foliage is not unfrequently applied for ornamental purposes in the worst possible manner, but when well designed and executed upon correct principles, not overlaying the architecture itself, then it vastly improves the works to which it is added. There are, however, many cases where it is injudiciously excluded, and there has been, in times past, a tendency to substitute for it plain moulded work. In numerous instances, there is a fatal obstacle to the introduction of foliated ornamentation, because of its expense and costliness; but we not unfrequently see very elaborate attempts at decoration by the adoption of intricate moulded work, which add but little to the beauty of the building. There are other cases, still more serious, where carving and sculpture of the highest class are added in the most profuse manner, but where the money and labour are entirely thrown away, because such decoration is applied upon an improper or false principle. In all early forms of art we find plain surfaces invariably used for the development of painting or sculpture. In the Egyptian and the Assyrian, walls were made eloquent by hieroglyphics and sculpture embracing animal and vegetable forms. In the Indian, Persian, Moorsque, and the Arabian, the same principle was adopted; the buildings of these nations were literally covered with elegant combinations of foliated form, and plain moulded work is scarcely to be found. Yet all these elaborate enrichments were not added to or upon the works, but were taken out of them, and therefore they did not destroy their breadth or character. It is in Greek architecture that we first see a development of plain surface, where although friezes and pediments were enriched with matchless sculpture, still architraves, cornices and walls were left plain and bare, or were enriched only with plain moulded forms. The Greeks, however, appear soon to have disliked the appearance of many of their plain surfaces, and supplied the deficiency by painting. They then covered their plain architraves with the meander, their unsculptured mouldings with the anthemion and other ornaments, and the lacunaria of their ceilings with the star or arrangements of foliated forms. The Romans carried out the enrichment of their mouldings with sculpture to a greater extent than the Greeks, and they also enriched their friezes with many fine arrangements of foliage associated with animal form. But besides these they enriched many of their plain surfaces with sculptured foliage, as in the architraves of their entablatures, as well as the coronas and soffits of their cornices. They greatly developed and perfected the Corinthian capital, and added foliage to the Ionic capital, producing what has been called the Composite, and so considerably enhancing its beauty as an enriched capital. They panicked too, some of their pilasters with grand and magnificent foliated scroll-work. Unfortunately, however, with the exception of these last, this decoration must have been placed at too great an elevation to have been properly seen. It was left, however, to the modern Englishman to carry out these antique styles devoid of all enrichments or sculpture, except long lines of bare moulded form. He is the only artist who deliberately sits down and wastes his time over the contours of quirks and ogees, and

by the aid of the plasterer's mould runs his entablatures, and borders all his windows and doors with his surprising combinations of mouldings. His plain surfaces are relieved only by scratching upon them lines to indicate colossal blocks of stone. Happily this phase of architecture is now nearly extinct. I would, however, call your attention more particularly to the improper application of decorative sculpture. Owen Jones told us that "construction should be decorated, and that decoration should never be purposely constructed." Yet we constantly see buildings erected where the so-called decorations are added to or applied upon the architecture. Festoons and awags of gigantic size are pinned up to the surface of the walls by pateras or lions heads, and tied there by impossible ribbons, while little window pediments are broken in the centre in order that their cornices may be piled up with immense loads of sculpture or foliage. In many modern French ceilings festoons of *papier mâché* are frequently introduced, actually hanging away from the ceiling, looped up by their extremities. Surely no greater violation could be imagined than thus to separate or hang enrichment up, as if ready to fall upon the spectator's head. Unfortunately there is a precedent found in antique architecture for these applied forms. The Corinthian capital is not a composition which grows out of and forms a part of the column itself, like the grand old Egyptian capitals, but all the parts are applied or added outside the bell, which is the actual capital—a circumstance which has greatly aided the labours of the modern plaster-caster, but should not be the rule in architectural ornamentation. No period in modern English architecture is more justly noted for foliated carving than that belonging to the school of Sir Christopher Wren, at the head of which stood Grinling Gibbons. For skill in workmanship, dexterity of manipulation and close imitation of nature, this period stands higher than any other. It is, however, extremely unfortunate that so much of this remarkably beautiful carving should be afterwards applied and added to the construction. Enriched ornament, to be true, must be subservient to the purpose and to the architectural forms of the work itself. The features themselves should be enriched, and as a general rule ornament should be taken out of the material—sunk below the surface and not laid upon it. A work may in this way be literally covered with ornament which may immeasurably aid its beauty, as in the walls of the Alhambra, or the elaborately carved but simple form of an Indian sandal-wood box. The great defect of modern ornamentation is that it is so often represented as if it had weight in itself, and that it was absolutely necessary to hang it up, or that it should stand upon its own base, as in many of the otherwise very beautiful Italian arabesque pilasters. The festoon, as a means of ornamenting a work, has been used in French and Italian Renaissance more than any other form, but it is essentially a bad one, and it is at the same time one of the most objectionable forms of constructed ornament. From its very nature it is added to the thing ornamented, and is formed of an artificially constructed collection of miscellaneous flowers and fruit: It is not only made up of all manner of flowers and fruit, strung together without any cohesion of parts, but of nearly everything that can be imagined, such as musical instruments, dead birds, shell-fish, and a multitude of other objects, as well as the ever-indispensable ribbon. Grinling Gibbons appears never to have been able to get on without festoons, ribbons and drops, or pendants in his work. The example of a panel from St. Paul's Cathedral is a good specimen of this. It is executed in the usual manner that he adopted for nearly all his most important works; that is, it is carved in lime tree and planted upon an oak panel. The composition is rich and bold, but somewhat confused. In the centre there are a pair of cross trumpets tied together by a ribbon. Then there are in the upper part interlacing scrolls of a conventional type peculiar to Gibbons. Out of the upper part of the scroll there drops a swag or festoon of small flowers, either periwinkles or primroses, which runs to the upper angle of the panel, and from which, hung to a single flower, drops perpendicularly a bunch of trilobed leaves, forming the end of the design. But besides this there is a larger and bolder swag, in much higher relief than any other part, extending from the knot of the ribbon at the junction of the trumpets, sweeping to the bottom of the panel, and going right up to the extreme

angle again, from which the smaller festoon and drop hang. This is repeated in the other half of the design, all, except the scrolls, being supposed to be hung up by artificial means. The peculiarity of Gibbons' scrolls, is that instead of the leafage forming a sheath, as in nearly all Classical foliage, it grows out of the stem itself or arises from the other side of the stem. The leafage is from nature, sometimes taken evidently from the hawthorn, and in other cases from the celery-leaved crowfoot. In richer work, as at St. Paul's, the leaves are double—that is, one lapping over the other. A defect in these latter scrolls is that they grow in two directions—that is, out at both ends, which might have been easily avoided. The fruit and flowers in Gibbons' festoons are all accurately and very beautifully copied from nature, consisting of peonies, anemones, crocuses, primroses, tulips, peaches, peas, and other fruits. All are separate and disconnected, except occasionally, by some faintly carved lines or strings at the back. No part is growing but is in "still life," and all are separately fastened in their places by means of screws, nails, and glue, and where the fruit or flowers are in very high relief, they are not worked out of one solid piece of lime-tree, but are formed of different layers of wood, about two inches thick, placed one upon another. There is no undercutting, properly so called, as the whole is backed off behind, and shaped previously to its being planted on the ground, which gives the work as much relief as if it consisted of actual flowers. In a few cases all are carved out of the solid. His panels are made up in two different styles—the natural in the festoons, and the conventional as seen in the scrolls, a manner of mixing up the natural and conventional common to most of the foliated work of the Renaissance period. Natural ivy, vine, oak, and other leaves as well as fruit, are introduced among purely architectural foliage in such an incongruous manner that they never properly amalgamate with the other portions of the composition. Gibbons went in boldly for nature in his own style, and whenever he adopted the natural he made the conventional quite subservient. But in the French and Italian the natural is usually introduced as if it were only an accessory. We, in the present day, should throw aside all architectural precedents for foliage, except the principles upon which they worked, and boldly make our applications directly from nature. Instead of doing so, we are often so bound by conventional rule, that we are not likely to succeed but in a partial degree, and by adopting two different manners we must fail in harmonising them. But artists and carvers are told by architects, and one hears it continually held up as law, that foliage for architectural purposes *must* be highly conventionalised, that it must not be too natural, and so on. I was in a lately restored church the other day, and I remarked to the clergyman, "Why, what common-place designs all your new poppy-heads are." "Oh, yes," he replied, "our architect prefers them; the carver wanted to make some of them different, but the architect would not allow him to do so, but would insist upon his copying the old ones." In this manner, only too common a case, we are constantly trying to resuscitate the ornament of former ages, and the plan will bring with it nothing but disappointment. The best positions for foliage upon a building are in friezes, mouldings, string-courses, panels, and diapers. In panels and spandrels we find the greatest development for foliage. In all cases keep the most important sculptured decoration as low down as possible in a building, and do not throw away work by placing it too high to be properly seen. In the upper parts I would have ornament of a more simple character and arranged to suit the respective heights.

(To be continued.)

HOUSEHOLD SANITARY ARRANGEMENTS.—VI.

THE course of Cantor Lectures, at the Society of Arts, on "Dwelling-houses: their Sanitary Construction and Arrangements," was brought to a close on Monday evening last, when Dr. W. H. Corfield, M.A., gave the sixth and last lecture, the subject being "Water-closets, Sinks, and Baths, arrangement of Pipes, Traps, &c." The professor first explained a diagram representing the section of a ventilating man-hole, in which air was admitted at the lower part

of the sewer and passed up a ventilating pipe or shaft, of which the top was covered by a grating. A water-trap was formed by a siphon bend, and an upright piece was fitted to a plug, which would be taken off so that rods might be pushed down to clear the pipe. A man-hole is not necessary for ventilating drains; all that is necessary is an opening of sufficient size, say 6 in., directly into the drain, between the siphon trap and the house wall. The simpler form of water-closet is the Hopper Closet, consisting of a conical basin with a siphon trap at the lower part of it. Beer, Dent, and Hellyer's Artisan Closet, the pan being provided with a flushing rim, was exhibited as an example of this kind of water-closet. Water scarcely stood in the pan at all, but in the trap below. A flush-pipe should never be less than 1½ in. in diameter, and ought not to be connected with the main water-pipes. Such a connection was doubtless the cause of the epidemic of typhoid fever at Croydon in 1876-7. In the Vortex Closet the siphon was much deeper than in the Artisan, and the water stood in the basin a considerable height. The water is discharged into the middle of the basin, and there is a ventilating-pipe to take off foul air. It is advantageous to supply closets indirectly by service-boxes holding about two gallons. Specimens sent by Hayward, Tylor, and Co., and Tylor and Sons were produced. When the handle is pulled only the water in the service-box can run out, because a ball-cock is raised and the tap turned off. One service box exhibited had a provision for an after-flush, which supplied the basin with water to remain in it. Jennings' Monkey Closet had a provision by which the basin was in such a position that water must remain in it under all circumstances. Woodward's Closet is provided with a flushing rim; and Bossing's Closet supplies water by one pipe with two branches, the whole contents of the basin being washed into a vertical pipe leading into a siphon. Behind the closet is a vertical opening fitted with a cap, which can be removed if the siphon be stopped up, and there is also an overflow-pipe; but this latter the Professor considered useless. Dodd's Wash-out Closet has a provision for ventilating the soil-pipe at the place where the siphon enters it. Fowler's closets are used in poor neighbourhoods where there is an insufficient supply of water. In this system sink, rain and waste waters are collected, and made to flush the closets. A plan submitted by Messrs. Doulton was shown. The Pan Closet is most commonly used in the interior of houses, and is a mischievous contrivance. A sample was produced. The basin is placed above a metal pan, which moves in a large iron box called a container. The container has a 4 in. outlet at the lower part of it, and below the floor is a trap—generally a D-trap. The container is simply a reservoir of foul air, and a great deal of that gets into the house, as the pan does not fit airtight. This closet will in time surely go out of use. A D-trap, so called from its shape, has a pipe inside it which dips into water for a certain distance. Foul matters collect in the angles, and it can never be cleared out by the water. Such a ridiculous contrivance ought not to be used under closets. A proper trap there is a siphon trap of cast-lead, similar to model produced. A leaden tray is usually placed underneath the closet apparatus to prevent any overflow from becoming a nuisance. It is called the safe, but any other word in the language might be better applied to the contrivance. A waste-pipe is carried from the safe, generally into a D-trap, and the overflow-pipe from the cistern is generally carried into the trap of the nearest water-closet. There never should be such a direct communication between the house and the foul air in the D-trap. The waste-pipe might be carried through the wall, and made to end outside, and no trap was required. Brahmah's valve-closet as exhibited has a small airtight valve in the lower part of the basin. Overflow is provided for by holes in the side of the basin, communicating with a pipe which passes down generally into the valve box; and there is a siphon to prevent air going into the basin. Specimens sent by Tylor, Hayward and Tylor, Deer and Dent, and Boddings, were then pointed out. Jennings uses for a valve an indiarubber ball, fitting over the end of the waste pipe. Air coming in presses the ball down on to the top of the pipe that leads to the overflow pipe. Water from the overflow pipe could raise the ball and pass beyond. In Tylor's closets there is a galvanised iron siphon trap underneath; it only

requires to be attached to the closet, without any trap whatever. A cap with screws on can be taken off, and the interior got at for cleaning. Jennings has a similar closet, which is also complete in itself. A specimen of Jennings' Solid Plug Closet was shown. The plug is not solid literally, but has in it a contrivance for the overflow. It is provided with an indiarubber ring, fitting water-tight upon an aperture leading from the pan to the base of the closet. There is always water in the basin and in the siphon trap below. When the plug is lifted the water in the basin runs away and swells out the siphon below, if there is one. These closets are largely supplied without traps at all, and, if the sewers be properly ventilated, the Professor believed they would be a successful experiment. Mr. Saxon Smithies' closet is fitted with a duplex lid, which opens out behind into an air-space—a shaft carried above the roof of the house. The water supply apparatus works with the lid, and the closet is excluded from the house. Water waste-preventers were then dealt with. Amongst these were the service boxes previously spoken of. A glass cistern sent by Tylor and Sons showed a water waste-preventer inside it; when the handle is pulled the whole valve is lifted up. The lower part of the valve has an indiarubber ring, which, by pressure of the water upon it, and by force of adhesion, carries up a weight with it. Water is gradually admitted into the space above the weight, and after a time the weight falls and closes the valve. With Underhay's regulators, if the handle be pulled and released immediately, as much water will flow as if it be held up a long time. A lever works a valve, which turns off the water, and the rate at which the valve is closed depends upon the rate at which the lever can be made to fall. This is regulated by a bellows, and there is a stop-cock, which may be so placed that it will allow the lever to fall slowly, quickly, or not at all. The amount of water delivered each time the handle is pulled may be regulated with the greatest nicety. Mr. Jennings has made an ingenious improvement, in which the regulator works upon the principle of a plunger. If the handle is pulled up, and let go in the ordinary manner, the waste-preventer does not come into action; but if it is held up, after a time the plunger is no longer sustained, and the waste-preventer comes into action and turns off the water. In dealing with soil-pipes, the Professor said that they were largely made of milled or seamed lead. Those pipes gave way at the joints, in consequence of the action of sewer gas. The pipes should be of drawn lead, made in the same manner as wire, and they would then only require to be joined at the ends of their lengths. Iron soil-pipes are sometimes used, and they vary less in length than lead when subjected to extreme changes of temperature. Where expense is not objected to, the Professor thought it better to have lead pipes the whole length, and where necessary, they might be protected by square iron pipes, like rain-water pipes. Earthenware pipes are sometimes used for soil-pipes, but he considered they are not good things. An example of a zinc soil-pipe was shown, with a D-trap of very thin lead, into which the waste-pipe from the cistern was brought. The zinc pipe was quite eaten through by the foul air. Lead pipes, not ventilated, contain foul air, which eats into them. A specimen was produced, taken from under a bedroom floor, and full of holes. He did not think a D-trap underneath a closet was any good. Sinks ought to be disconnected from the drains; but if it be necessary to disconnect closet-pipes, it shows that the sewers are not properly constructed or ventilated. Sinks and baths should have pipes which are discharged over areas, upon gratings, or under gratings and over traps. It is always proper to have a trap of some kind upon a sink. A D-trap is objectionable. A bell trap in its ordinary shape is about the worst contrivance ever devised. A difference in the pressure of the air is enough to bring air from the sewer into the house; and the water into which the bell dips evaporates. In Jennings' sink trap the bell is not removable—but only a piece of perforated galvanised iron. In another variety the bell trap is hinged. Sinks up-stairs have a long pipe in which, although the pipe may be disconnected, foul air accumulates, and a trap is therefore necessary. Jennings' sink, largely used in model dwelling-houses, instead of a lot of holes, has a slit sufficiently small to prevent pieces of soap and other things going into the drain, but

it allows the water to run away easily. The aperture into the waste pipe can be stopped, and the sink used for washing. The siphon gully Mansard trap contains three compartments through which the water passes, and is useful for scullery sinks. Pipes from baths require a trap upon them and require to be disconnected. A vote of thanks to Dr. Corfield for the able and clear manner in which he had delivered his very instructive lectures was carried by acclamation.

SOME OLD HOUSES AT EXETER.

WE do not appreciate our mercies until we have lost them, is a common saying; and I realised the truth thereof very keenly when I read in a local paper of the narrow escape some quaint old houses in Exeter had recently. The publication in question narrated how, at a fire the other night in the West Quarter (the most ancient part) of Exeter, the flames nearly caught the half-dozen houses that stand upon what remains of the original old Exe Bridge. "These buildings," the report went on to say, "are the oldest in the city, and are such ramshackle, tumbledown places that their removal would be a public benefit." That was the newspaper reporter's prosaic opinion of as picturesque a group of buildings as I know! They always suggest, whenever I look at them, old London Bridge; and I think that hardly anywhere, save, perhaps, in odd corners such as one meets with in the elder part of the town at Cassel, will a cluster of buildings be found that, in all its bearings, carries one back so completely into a past age. It is often my pleasant task to point out to strangers who may be sympathetic lovers of domestic architecture, unfrequented "bits" in this ancient city; and I always reserve these houses till the last, saving them as a savoury morsel, as it were, after those of lesser interest have been inspected. It is with much regret, therefore, I must add that what the fiery element has spared them, the hand of Time has not dealt tenderly with; and, from a recent personal inspection, I very much fear they are doomed. Before many more years have run their course, these houses, like numbers before them, will have passed away, and only in the recollection of a few will their very existence be remembered.

Hence it seems that a note or two thereon is well timed. The old bridge over the Exe was built about 1250. It had twelve arches, and though much of it was destroyed during a great flood in 1449 and more of it collapsed in 1539, several of its arches stand till this day. The main road and traffic do not go over this now, however, for a new bridge, known as the Exe Bridge, was built and opened in 1773 a little higher up the stream, and the road was diverted to meet it. It is against the eastern side of the remaining fragments of the original bridge that the houses I refer to stand. Within the memory of many still living, somewhat similarly constructed buildings stood upon the opposite side of the bridge too. These were almshouses, and beside them, also on the bridge, was an ancient chapel to Our Lady, described in an existing deed so early as July 8, 1380. This chapel and the almshouses were taken down in 1833. Seen from the higher side of the water, the houses group very pleasantly. Upon the right hand is the western end and tower of St. Edmund's Church, a Perpendicular building, built of the warm red local stone, Heavitree or Pocomah. The stream just here is about forty yards wide; this is not, mark, the main portion of the Exe, but an arm of it, which joins the principal part again lower down. Three arches span the water, and upon each of these stand two houses. Upon the one end they abut right up against St. Edmund's tower. The middle opening is the widest, and the abutments are solidly built of the local stone already alluded to. Across them are huge oak beams supported by divers struts and corbels of similar material, and upon these the houses stand: the timbers being more or less bent with the strain upon them. By peering underneath, into the semi-gloom that exists there, it will be seen that, further in, the dark waters moodily flow through, not the piers only, but the actual old arches, or at least a part of them. These are under the roadway farther in than the houses. I regret very much that I do not hold the facile pencil of an Ernest George or a sketch of this interesting group should be published ere it disappears from mortal ken altogether. In each instance the lower

floors project out in open corridors over the water, and in one case stone steps lead down therefrom, against the pier, giving the inhabitants thereby access to the river beneath. These places are used by the occupants as washhouses, &c., and the clothes that may generally be seen hung out help the picture not a little. The two central houses are altogether more prominent than the others, and on one side assume a turret-like shape. The buildings are constructed entirely of timber, and in the main, are plastered. The window casements retain, in most instances, their old lead lights. The window openings are diversified, some curiously small (not a foot square), whilst the larger ones are invariably wide and low. The roofs are covered with slates, all of which, save over one house, are old. The height of these buildings above the water-line varies from five to twelve feet. The river flows over a sparkling, rippling weir on one side, before it pops in between the abutments; and this all helps the old-world look of the picture.

Seen from the other side—that is, from the roadway upon the Westgate Bridge—it will be found that the buildings are inhabited by folks in very humble life. The two houses nearest the church, after having for years exhibited the sign "Lodging for Foot-travellers," are now unoccupied, and it is not probable that they will be relet. It was here that, until recently, German musicians and the prettily-attired wayfarers who affect Italian costume used to find a resting-place; and very much in keeping they would look as, on a Sunday morning, for instance, I have seen them lounging about at door and over window-sill. These old houses have undoubtedly served their many generations; and now in their last days they retain to the full that quaint interest which gives that character and individuality to our old city of which no one is more proud than is the writer,

HARRY HEMS.

[Mr. Hems has sent a small sketch of the houses; but it is unsuitable for reproduction, or we should gladly have published it.—Ed.]

AMERICAN ENGINEERING.

WE have received the first number of the "Proceedings of the Engineers' Club of Philadelphia"—a club which has recently become organised, and which owed its origin to a few social gatherings of young engineers in Philadelphia during 1877. The number before us contains several useful papers of a practical character relating to engineering questions, many of local interest merely, but some of general value. The house and street drainage of Philadelphia is the subject of one paper by Mr. Rudolf Hering, C.E., in which the author advocates pipe sewers 12 and 15 inches in diameter instead of larger sewers, on the score both of economy and efficiency. The author, speaking of main sewers in Philadelphia, says, "I believe we could reduce the size of our main sewers nearly one-half without running any risk . . . the smaller the sewers the easier it is to ventilate them, and the greater will be the velocity for the same amount of sewage, and the more effectual the discharge." Frequent openings in the streets for the free entrance and exit of air is thought the best means of ventilation. As regards rainfall, Mr. Hering says that the sewers of Philadelphia are much too large; one inch of rainfall is calculated upon, but that there has never been a shower sufficiently heavy to fill any of the largest sewers, provided they were not tide-locked. If provision for half-inch rainfall per hour were made, it is thought to be ample. In New York, calculation for one inch is made, but it is shown that this estimate requires large and costly sewers, especially where the drainage areas are large, while the necessity for still more costly systems increases. Another paper, entitled "Empirical Formula for Strength of Wrought-iron Beams," by Mr. Percival Roberts, contains a few useful remarks. The empirical formula, has given the author remarks, very good results in practice, and is further convenient for rough calculations. We give it here:—

$$\frac{1}{3} \left(\text{area in sq. in.} \times \text{depth of bar in inches} \times 4 \right) = L$$

length of space in feet

L being the safe load in not tons, uniformly distributed upon a laterally-supported beam. If the load is in middle, the result must be divided by 2; if at any other point, the proportion of the rectangle of the segments to the square of half

the space must be taken. The weight of the beam is deducted from the results obtained. In the tables of the Phoenix and Trenton beams which follow, the calculated safe loads are very close to the results obtained from the above formula, the Phoenix giving from 3 of a ton to more than 2 tons more weight for a load upon the same section of beam (I-shape) than is obtained by the formula, while the table of the Trenton Company gives about as much less. The formula gives therefore a mean between the two. If we take an example from the tables, a beam of 10ft. span 9in. deep, 150lb. per yard, the Phoenix safe load is put at 19'70, while the formula gives 18'00 net tons. The rule, therefore, of Mr. Roberts gives a result exact enough for practical wants, where strict theoretical accuracy is not required, and as pointed out by Mr. Christie in the discussion, while it is too low for thin-webbed is too high for thick-webbed beams. Another paper by Mr. P. Roberts on the "strength of wrought iron in structures" reviews some valuable evidence upon the tensile strength of wrought iron. The author refers to the "Experimental Inquiry" of Mr. David Kirkaldy undertaken for the Messrs. Napier and Sons, published in 1864, in which that keen-sighted experimentalist points out the importance of closely observing the shape of the test piece with reference to the tensile strength obtained, also that the testing machine should be perfectly reliable. We may here give, in the words of the author, an important conclusion that cannot be too well known: "He found that if a bar, instead of being of parallel section, be turned down by sinking a fillet into it so that a minimum section occurs at but one point, that specimen would stand a much higher strain before breaking than a piece from the same bar whose section was parallel, the former contracting none whatever at point of rupture, while the latter would be much reduced. The mean of fourteen experiments gave, on the grooved section, 73,942lb. per square inch, while the same bars, not grooved, showed but 62,256lb. per square inch, a difference of 11,686lb. in favour of the grooved section!" The author considers such a grooved section utterly worthless as a test in specifications to give information, as it represents an artificial condition that rarely occurs in practice; on the other hand, the parallel section represents the most ordinary case of use. "To ascertain the limit of elasticity very accurately is surely of more importance than to have the tensile strength to within a few thousand pounds; for, strain a piece beyond this limit, and no matter what its ultimate strength may be, it is but a question of time when rupture will ensue." These remarks are sensible, and we endorse the opinion that if our "factors of safety" were proportioned to the elastic limit rather than to the ultimate strength, much safer and more accurate results would be obtained. Another suggestion as regards tension members is that they must be "double rolled from the muck-bar direct," to use a specification phrase. The practice of reducing and re-rolling bars is an additional security, as the bar by this process gets rid of the poor iron it may have in its composition. The "Scales of Maps," by Mr. Lewis M. Haupt, president, is the title of a paper pointing out the ambiguities existing in the use of ratios as expressing the scales of maps. The term "ratio" is not agreed upon, and confusion exists in designating the scales of maps and drawings. The author establishes the definition of a ratio "as being the expression for the value of the relation existing between two quantities, and as obtained by dividing the second by the first." The given object to be represented by the drawing should be considered the first, being the unit or measure with which the other is to be compared. Thus a scale of 1-5280 is 5,280ft. of field to 1 foot of map, or 1 mile to 1 foot = 1-12th of a mile to 1", and not 12" to 1 mile. It is shown, therefore to be inaccurate to indicate the scales of maps as so many inches to a mile—a very common mode of expressing scale. The expression $\frac{1}{2}$ " to 1' is also in the same manner incorrect, the inches evidently referring to the drawing and the foot to the object represented. It should be 1' to $\frac{1}{2}$ "—the antecedent referring to the object and the consequent to the drawing.

The Town Council of Harwich have obtained the sanction of the Local Government Board to the borrowing of £10,000 for the proposed drainage works, to be carried out from the designs of Messrs. Russ and Minns.

COMPETITIONS.

SPALDING.—The prosperous market town of Spalding, situate on the River Welland, is to become the possessor of one of the most useful institutions of ancient or modern times in the erection of the Johnson Hospital, for which a competition was advertised some months ago. For the accomplishment of this object every precaution has been taken by the charitable lady at whose expense the institution is to be erected, and we understand, endowed. From sixty sets submitted the number was reduced to twenty-five, as we stated last week, and afterwards to six, the authors of these being Messrs. G. G. Hoskins, Darlington; Giles, Gough, and Popplewell, Craven-street, London; F. L. Simpson, Wakefield; L. P. Grace, 38, Wigmore-street, London; Lloyd and Lunn, Leamington; Shields and Routhwaite, Sunderland. Since then the first premium has been awarded to Mr. G. G. Hoskins, and the second to Messrs. Giles, Gough, and Popplewell.

THE ORME BILLIARD TABLE DESIGN COMPETITION.—Messrs. Orme and Sons, of 11 and 13, St. Ann-street, Manchester, offer £120 for designs of billiard tables, &c., as below:—Class 1. £50 for the handsomest design of a billiard table, of any style. The design to be of a rich character, and regardless of expense in manufacturing. Class 2. £25 for the best design of a billiard table suitable for a house, of no special style or character. Class 3. £15 for the best design of an inexpensive billiard table. In this competition the judges will be instructed to select the table that combines the best effect with the least expense in manufacturing, a table for the million being the desideratum. Class 4. £10 for the best design of a marking board, combining the arrangements for scoring the games of billiards and pool. All the above designs must be drawn in ink. Class 5. £20 for the best sketch of an interior of a billiard room, ideal or otherwise, showing all or part of the billiard table, marking board, &c. This drawing must be in perspective, and not less than 20in. by 15in. This drawing may be executed in ink or in colours. With each design there must be a side view of the billiard table, drawn one-twelfth of full size, and another showing one leg, and a small portion of the side drawn to one-fourth the full size. It is not necessary that working drawings be sent, but if required they will be asked for. Drawings gaining a prize become the absolute property of Messrs. Orme and Sons. The drawings not gaining a prize will be held by Messrs. Orme and Sons, six months from the date of award, for the purpose of public exhibition, and on any orders being taken from any of the designs, not the prize designs, during that time, a commission of 2½ per cent. will be paid to the author of such design, but such commission will not be given on designs which are similar to those that Messrs. Orme and Sons have already executed work from. Competitors not gaining a prize may allow their drawings to remain with Messrs. Orme and Sons permanently, who agree to pay 2½ per cent. on all tables made from such design, within three years of the date of award; but such commission will not be given on designs that are similar to those that Messrs. Orme and Sons have already executed work from. Competitors must have their drawings delivered at 11, St. Ann-street, not later than June 18th instant, and all packages must be carriage paid. The judges are W. J. Muckley, Esq., of the School of Art, Manchester; E. Salomons, Esq., F.R.I.B.A., architect; and Mr. James Lamb, cabinetmaker, of Manchester.

THE STOKES-UPON-TRENT SEWAGE COMPETITION.

—In response to the invitation of the Town Council of Stoke for schemes for the treatment of their sewage upon seventy acres of land recently acquired about a mile from the town, twenty engineers sent in plans and reports upon the day named, the 8th instant. The lowest estimate for the entire work, which included the completion of the outfall sewers, the formation of roads and approaches, the laying out of the land and the works for the treatment of the sewage was £4,311, and the highest £20,710. Five of the estimates were under £10,000; twelve ranged from £10,000 to £15,000; two were under £20,000, and one was over £20,000. Eighteen of the twenty engineers advocated irrigation; two recommended precipitation by lime or chemicals, and downward filtration. Of the eighteen who recommended irrigation twelve advocated subsidence in tanks without chemicals and downward

filtration, and six recommended lime or chemicals for the purpose of precipitation. Six of the schemes recommended along with irrigation subsidence in tanks and downward filtration. The plans of Major-General Scott, C.B., F.R.S., of Ealing, and Mr. Gilbert R. Redgrave, who submitted a joint scheme, were unanimously awarded the first premium of £150. Those of Messrs. Bailey, Denton, Son, and North were selected for the second premium of £100. The scheme of Messrs. Scott and Redgrave involves the use of power for pumping the sewage, obtained by improvements of the Trent; the treatment of the sewage in tanks by the lime process; the employment of intermittent downward filtration for the night sewage, and the irrigation of the whole of the farm with the clarified effluent from the tanks. The total cost of the system is set down at £10,890, distributed as follows:—Improvements to the river, £875; roads and approaches, £695; completion of the outfalls, £4,065; preparation of the land, £920; and tanks, works, and machinery, £4,335. The scheme of Messrs. Baily, Denton, and Co. provides for an outlay of £14,032. It is proposed that Messrs. Scott and Redgrave shall carry out the work, in which case the premiums will merge into the commission.

Building Intelligence.

BLACKBURN.—A new Wesleyan Chapel, in Preston New-road, Blackburn, was opened on Thursday, the 20th inst. It is Gothic in style, of stone, with Bath and granite dressings. At the corner is a tower, with broach spire rising to a total height from the ground of 128ft. The chapel measures, internally, 78ft. by 60ft., and is fitted with benches of pitch-pine, varnished and stop-chambered; the pulpit is of pitch-pine and oak, and has a flight of stairs on each side. At the rear are the vestries. A gallery surrounds the chapel, and has a pitch-pine front. 1,033 sittings are provided. Beneath the chapel is a school-room 74ft. by 53ft., and 17ft. high, two class-rooms, each 14ft. by 11ft., fitted with revolving wooden shutters; a morning-chapel for week-day services, 35ft. by 21ft.; and two vestries. Mr. William S. Varley, New Market-chambers, Blackburn, was the architect, and Mr. E. Lewis, of the same town, the builder. The hot-water contract was taken by Messrs. Mercer Brothers, and that for gasfittings by Messrs. Freeman and Collier, of Manchester. The total cost will be about £10,000.

CARLISLE.—Rapid progress is being made by the contractors, Messrs. Morrison and Mason, in the extension of the Citadel Railway Station, about 300 men being employed on the job. The premises will be almost doubled in size. The platform on the east side will be greatly extended, so as to afford additional dock accommodation, and there will also be three sets of through lines, both north and south. The station will be about 1,000ft. long by 300ft. wide, and in the centre will be an island platform, 1,400ft. long. In the middle of this platform will be a suite of refreshment and washing-rooms, booking, parcel, and telegraph offices, and underneath will be kitchen, scullery, larders, wine and beer cellars, lamp, porters, and boiler rooms. These rooms will be lighted by Hayward Brothers' patent pavement lights, with semi-prismatic lenses, and communication will be made by hoists between the basement and rooms on the platform; while for passengers' access is provided to the platform both by subway, overhead bridge, and an inclined approach from the Viaduct. The station roofs will be supported on iron columns and girders, and will be glazed on Rendle's system. The works are being carried out from the plans of Mr. George Cunningham, C.E., engineer to the Joint Station Committee; Mr. W. Reid is inspector of works; while Mr. Waddell is the contractors' engineer, and Mr. Morton is their manager.

CHESTER.—A new altar dedicated to "Our Lady of Seven Dolours," was unveiled in St. Francis' R.C. church on Sunday last. The altar-piece is a life-size group of the Pieta, of Munich workmanship, which stands on a massive pedestal on the super-altar, under a deeply-recessed arch richly moulded and relieved with carvings of the Passion flower, leaves, &c.; in the spandrel of the gable above is carved a heart pierced by seven swords, types of the Dolours; a ribbon filling

up the same panel bears the following inscription in Latin—"And thy own soul a sword shall pierce.—St. Luke ii. 35." The gable terminates with a foliated cross, the height to top of which is 18 feet from pavement. The altar proper has an arcade of seven compartments in the centre, one of which is a panel with cross and winding-sheet; and in the other six are angles bearing emblems of the Passion. The altar has been designed and made by Mr. John A. Hauley, architectural sculptor, of Chester.

HAMPSTEAD NORRIS.—The work of restoring the interesting old church of St. Mary, Hampstead Norris, is about to be at once commenced, the restoration committee having accepted the contract of Messrs. Silver and Sons, of Maidenhead, for carrying out the alterations, according to plans prepared by Mr. Arthur Baker, architect, of York Chambers, Adelphi, London. The present church consists of a chancel, nave, west tower, and porch. The chancel is Early English. The nave, which is disfigured by most unsightly pews, has two lancet windows on the north side; those on the south side are chiefly Perpendicular. The north porch is plain Perpendicular; the doorway is Norman, with the billet moulding; inside is a deep Early English recess for the stoup; the south doorway is also plain Norman. The staircase to the rood-loft remains, and a small Perpendicular window to give light to it. The tower arch is Transition Norman, pointed. The tower is plain Perpendicular, with very thick flint walls. The roof of the nave is Jacobean, with the date 1635. On the north side of the nave the original stone consecration cross still remains.

INCORPORATED CHURCH BUILDING SOCIETY.—The Incorporated Society for Promoting the Enlargement, Building, and Repairing of Churches and Chapels held its usual monthly meeting at 7, Whitehall, last week. Grants were voted towards building churches at Abergynolwyn, in the parish of Llanfihangel-y-Sennant, Merionethshire, £80; Brynwyndham, in the parish of Ystrad-y-fodwg, Glamorganshire, £160; and Fairwarp, St. Mary, in the parish of Maresfield, near Uckfield, Sussex, £100; rebuilding the churches at Thimbleby, St. Margaret, near Horncastle, Lincolnshire, £45; and Trefilan, St. Hilary, near Talcarn, Cardiganshire, £80; and towards enlarging or otherwise improving the accommodation in the churches at Brassington, St. James, near Wirksworth, Derbyshire, £35; Friskney, All Saints, near Boston, Lincolnshire, £50; Hastingleigh, St. Mary, near Ashford, Kent, £35; Maresfield, St. Bartholomew, near Uckfield, Sussex, £50; St. John the Baptist, Timberhill, Norwich, £15; Narberth, St. Andrew, Pembrokeshire, £50; Todenham, St. Thomas-a-Becket, near Moreton-in-Marsh, Gloucestershire, £25; and Whetstone, St. John, in the parish of Finchley, Middlesex, £30. A grant of £30 was made from the Mission Buildings Fund towards building a mission church in the parish of St. Stephen's, Cardiff.

KENNARDNOTON, KENT.—The parish church of St. Mary, in the liberty of Romney Marsh, has just had its tower partially restored, from the designs and under the superintendence of John P. Seddon, architect, of No. 1, Queen Anne's-gate, Westminster. The present church is a comparatively small one, rearranged out of the ruins of a much larger one, which was partially destroyed by lightning in 1559. The result is a structure of singular picturesqueness and interest, consisting of a nave with south porch and chancel, the latter placed irregularly with regard to the nave, the north walls of both being in a line, while the chancel being much narrower than the nave, their central axes do not correspond. A north aisle once existed, as is evident by an arcade embedded in the north wall, and only visible on the outside of the church. The tower, which was to the west of this aisle, and in advance of the western walls of the nave and aisle, now stands isolated, and only attached to the nave at the south-east angle. There is a circular turret projecting from the north side of the tower, with a rude conical stone roof. Two magnificent middle-pointed traceried windows, partially destroyed and blocked, exist in the south walls of the chancel and nave. These are so far finer than anything else about the church, that they form a curious problem in themselves. The present condition of the church with that proposed, if it be possible, have been represented in two pictures prepared as a contrast by Mr. Seddon, and we propose to give

representations of them which may present a bone of contention for the Society for the Protection of Ancient Buildings, who may prefer the church in its squalor, with plastered ceiling pierced by the iron stove-pipe, with the rotten deal pews, to the view given with the windows mentioned reopened and refurnished with tracery, and the interior refurnished with screen and decorations as proposed. The work at present done, however, is confined to a faithful restoration of a crumbled and dilapidated western doorway and three-light window over, and a richly-panelled oak door with wrought-iron furniture, and the re-flooring and plastering of the interior of the tower, to serve as a Sunday-school room, as proposed by the Rector, the Rev. Sydney Loft.

LIVERPOOL.—The New Commercial Salerooms, Liverpool, were opened on Monday. The plans are by Mr. J. F. Doyle, architect, of No. 4, Harrington-street, Liverpool, and the works were contracted for by Messrs. Haig and Co., builders, of Fraser-street, Liverpool. The style is "Queen Anne," and the structure consists externally of a mixture of red brick, with Cefn stone dressings and unpolished Shap granite base. On the ground floor are offices, and a small private room for brokers. The rest of this floor is taken up by the fruit saleroom. This room and its approaches are lined with panelled dados of oak. In addition to offices, the first and second floors are fitted with lavatories, and the third floor is occupied by the keeper of the building. The total cost of the erection when completed will be about £15,000.

METROPOLITAN BOARD OF WORKS.—At the meeting of this Board on Friday, a long discussion took place with reference to the expediency of proceeding with the Tower Bridge Bill, the Government having declined to consider at the present time the extension of the coal and wine dues beyond £1,890 for that purpose. The works committee reported in favour of abandoning the Bill, but it was eventually decided by 19 votes to persevere with the Bill. It was decided to fence in Plumstead-common, at an estimated cost of £11,281 15s. The action of the Fire Brigade Committee in accepting the tender of Messrs. Stimpson and Co., amounting to £3,778, for the erection of a fire-station at Greenwich, was confirmed. Letters were received from the Home Office, transmitting letter from the Central Association of Master Builders of London, and copy of a statement of objections of their Association, and also of the London Builders' Society, to the By-laws made by the Board under the Metropolitan Management and Buildings Amendment Act, 1878, Section 16; these were referred to the Building Act Committee.

The Great Yarmouth Town Council have before them plans for providing additional house accommodation for the working classes on waste lands in their possession close to the town. One of these has been prepared by Mr. Baker, the borough surveyor, and shows a series of ten terraces running east and west, to be erected on land north of the workhouse, with 35ft. and 30ft. front roads, and 15ft. occupation ways between the double blocks. 234 houses are indicated, of which 216 have a frontage of 14ft. and depth of 35ft. each; these are estimated to cost £100 each in erection. The remaining 18 houses, facing the sea, would be of a superior class. An alternative plan for the utilization of the same site is that propounded by Mr. J. H. Bly, who proposes ten long streets running east and west, providing for the erection of 123 houses, with a frontage of 17ft. each, and gardens each 92ft. deep; no lateral streets are provided, but one plot in the centre is reserved for trade purposes, and another for a public building, and on the sea-front of these streets spaces are set apart for the erection of villas.

A new Wesleyan chapel was opened at Ladycross, near Launceston, on Tuesday week. The chapel is in the Early English style of architecture, and seats about 190 persons. There is a school-room 30ft. by 20ft., and a residence for the chapel-keeper attached, with a coach-house and stable behind. Mr. William Burt, builder, of Launceston, has carried out the work from plans prepared by Mr. C. P. Wise. The cost has been about £1,000.

At a meeting held at St. Matthew's Church, Walsall, it was decided to build an organ-chamber on the north side of the church, from the designs of Mr. Ewan Christian, of London. It was also decided to obtain estimates for the general restoration of the church in five sections, the proposed work including entire reseating, removal of galleries, and erection of three porches.

The Wareham Highway Board have elected Mr. W. W. Fookes as surveyor.

More than Fifty Thousand Replies and Letters on subjects of Universal Interest have appeared during the last ten years in the **ENGLISH MECHANIC AND WORLD OF SCIENCE**, most of them from the pens of the leading Scientific and Technical Authorities of the day. Thousands of original articles and scientific papers, and countless receipts and wrinkles embracing almost every subject on which it is possible to desire information have also appeared during the same period. The earliest and most accurate information respecting all new scientific discoveries and mechanical inventions is to be found in its pages, and its large circulation renders it the best medium for all advertisers who wish their announcements to be brought under the notice of manufacturers, mechanics, scientific workers, and amateurs. Price Twopenny, of all book-sellers and news-vendors. Post free 24d. Office: 31, Tavistock street, Covent-garden W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements and Paragraph Advertisements is. per line. No front page or paragraph advertisement inserted for less than 5s.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 3fr. 30c.). To India (via Southampton), £1 6s. 6d. To any of the Australasian Colonies New Zealand, the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

N.B.—American and Belgian subscribers are requested to remit their subscriptions by International P.O.O., and to advise the publisher of the date and amount of their remittance. If the last-mentioned precaution is omitted some difficulty is very likely to arise in obtaining the amount. Back numbers can only be sent at the rate of 7d. each, the postage charged being 3d. per copy. All foreign subscriptions, unaccompanied by an additional remittance to cover the extra cost of forwarding back numbers, are commenced from the next number published after the receipt of the subscription.

Cases for binding the half-yearly volumes, 2s. each.

RECEIVED.—T. and H.—S. P. J. Co.—A. T. M.—C. H. S.—J. M.—O. Bros.—L. Bros.

E. A. P. (Yes, the book is published by B. T. Batsford, 52, High Holborn.)—INQUIRER. (The angle of 45° is taken from the sill of window and measured from the vertical face of wall. The obstruction opposite is supposed to clear this line. The subject was explained in the BUILDING NEWS last year.)—STUDENT. (A work on "Quantities," by Mr. Banister-Fletcher, and Dobson and Tarn's "Guide to Measuring and Valuing," are both good books on the subject.)—T. O., Grimsby. (If we understand you, the block plan measures by scale 100ft., whereas the land measures 110ft., and the latter dimension was written in figures on the plan. The builder certainly ought to work to the figures in this case, unless a contract was signed before the plan was figured.)—A. F. M. (A class for the study of the figure from the life is held every Saturday at the Royal Architectural Museum, 18, Tufon-street, Westminster. The fee is 3s. a month.)

"BUILDING NEWS" DESIGNING CLUB.

ROBERT BRIGGS. (The rules were published Sept. 20th, 1878, and a copy of the BUILDING NEWS of that date may be obtained of the publisher.)

H. RAY writes anent the selected design for 3 cottages. (Your second query is reasonable: the door would have been better a little further away from front door—not so central. The kitchen would perhaps be a little dark. W.C.'s are not well arranged. Your other queries are trifling, and you must remember it is impossible to get a perfect plan.)

OUR COMMONPLACE COLUMN.

C. F. W. AND OTHERS. (Received. Our Commonplace Column is published every fortnight unless any pressure on our space precludes. This has been the only cause of delay.)—J. D. B., C. W., G. H. G. (Original notes or apt quotations on graining, granary, greenhouse, groined vaulting, grotesque, grot, gutter, gymnasium, habitable room, hagiocope, half-timber, hall, &c., will be received on or before the 8th of April next.)

Correspondence.

THE ARCHITECTS' BENEVOLENT SOCIETY.

To the Editor of the BUILDING NEWS.

SIR,—In consequence of Mr. Mocatta's, the chairman's, remarks at the recent general meeting of this Society (see *Builder*, March 15th, 1879, page 293), urging the necessity of increasing the amount of the invested capital on account

of our frequently being unable to deal with all the distressing cases coming before the Council in a way adequate to the needs and deserts of the applicants, I have had a letter from one of the leading members of the profession—one who is serving on our Council, and who knows the good work done there—offering to make a donation to the Society of £100 if fourteen other gentlemen can be found to do the like within three months, so as to raise our funded stock over £5,000.

May I ask the favour of your giving this fact publicity in the columns of your paper, and thus oblige, yours, &c.,

J. GOLDCUTT TURNER, Hon. Sec.
15A, Wilton-street, Grosvenor-place, S.W.,
March 24.

CHAIR FURNITURE, &c.

SIR,—In your notice of my patent chair furniture in your last number you spoke of me as "the architect of Westgate-on-Sea." My connection with that place, which has ceased, was the starting it as a building estate by the erection of some bungalows there, four of which, freehold and furnished, were bought by Professor Erasmus Wilson. These formed the nucleus of what has since been developed into the flourishing town of Westgate.

I afterwards moved to, and have remained at, this place, "Westcliff, Birchington-on-Sea," 1½ miles westward of Westgate, where I have continued my system with great success, selling bungalows, freehold and furnished complete, even to a corkscrew, to gentlemen of position. Here I have gradually developed and perfected inventions for the construction of wooden bungalows, such as that in which I reside, and of their "chair furniture," of which you have given so favourable a notice.

Though called "chair furniture," and easily converted into various articles, their component parts of chairs and stools are not readily observable, so as to invite the "wizard's wand," unless real convenience require it.

By the inventions above referred to I am now able to export to any country not a mere shell of a house, but a complete bungalow residence, furnished with appropriate chair furniture, the whole safely packed in a small compass.—I am, &c.,

JOHN TAYLOR.
Westcliff, Birchington-on-Sea,
Thanet, March 25.

THE ARCHITECTURE OF THE FUTURE.

SIR,—In all ages architecture has found its highest form of expression in religious edifices. Why? Because real religion is the embodiment of man's deepest, noblest, most earnest aspirations. It is only natural for men to lavish their greatest skill, knowledge, and patience on such objects as most vitally affect their every-day lives. Therefore, it is not too bold a thing to say that it is not to our churches that we must look in the future for the highest development of architecture. How can we reasonably expect men to expend their best abilities on buildings which are used only for a few hours on one day in the week?

In the Middle Ages the Church was paramount there was but one form of religion in the land, men were earnest in their worship, and the result was that building arose which, in their way, have never been surpassed. The prevalent spirit in this respect was then more like that which exists in Belgium at the present time, where the churches enter largely into men's daily lives, and are not merely visited once or twice a week by respectable and wearied congregations. It would be equally useless to greet this change with joy or regret; it is enough to acknowledge it and act accordingly.

But if not in ecclesiastical edifices, where may we expect to find the highest development of our art? The answer has already been given—in those buildings with which men's most earnest aspirations are identified; in schools, colleges, hospitals, town-halls. Look at Manchester. She can produce a town-hall which is, perhaps, unrivalled; but she cannot build a cathedral. Everyone will help towards the former; only one sect will materially aid the latter.

There are few things more depressing than the prevailing notion that a building must be in some accepted style. "What style is it?" is

the first question; and if the architect cannot straightway give a satisfactory answer, his work is regarded with disfavour. The consequence of this is that church-building is little more than the solving of various archaeological problems, which different men affect with differing degrees of success. Every new departure is a revival. A revival! Why the very name condemns it. It is useless to try to pass off as a living man a ghastly galvanised corpse.

Of course, a new style cannot be invented at once; it must grow. But if men will only free themselves from the notion that new buildings must be built in some ancient style which has had its own good day, and died: if they will accept new materials and work upon them as artists, fulfilling in all ways modern requirements, we shall see the much-desired new birth. Meanwhile, it must be confessed that these conditions are being fulfilled more completely by engineers than by architects.—I am, &c.,

March 25, J. A. G.

BUILDINGS IN BOND STREET.

SIR,—Whether the shop, illustrated in your last week's number, merits the title of an "important addition to the street architecture of London" admits of question. Several "important additions," that is to say artistic and interesting buildings, have lately been made in the street, but those persons who have at heart the dignity and improvement of what the Earl Beaconsfield styles the most interesting thoroughfare in Europe, will probably consider the design under notice, and those premises a little above of the Messrs. Chappell, as veritable eyesores. Can you state, Sir, what is the particular style intended? The general appearance, in consequence of the window-heads being corbelled, is Gothic; but round arches, and the moulded pediments to upper windows and the doorway, are as decidedly Classical in character. The ironwork may be described as nondescript. Its want of vivacity in design is, however, more than compensated for by its being painted pea-green. The finial, on turret roof, is a caution. The description states that the carving is typical of the proprietor's cheese and butter business. I don't know how this may be, or whether the said business is supposed to have inspired the *motif* of the design generally. *Buttery* it may be—a compound of strange and questionable elements—but in my humble opinion it assuredly is not "the cheese."—I am, &c., M.

CHIPS.

A substantial red brick building has been erected on the Worcester-wharf, near Bridge-street, Birmingham, as a hall for the use of the canal boatmen passing through Birmingham. The building is three stories high, and contains on the ground-floor, large coffee-room for men with lavatories, and drying-room; coffee-room for women, with lavatories and a kitchen. On the second-floor is a lofty hall seating from 150 to 200 persons, vestry, caretaker's parlour and lavatories, and on the third floor are caretaker's bed-rooms. The architects are Messrs. Osborn and Reading, and the cost has been about £2,600.

The London School Board at their meeting on Wednesday ordered the school in Gillespie-road, Highbury-vale, N., to be enlarged by 200 places; the work will be carried on a schedule of prices by Mr. E. Lawrence, whose tender, amounting to £11,527, was accepted in May last for the erection of the original school for 1,000 children. The following expenditures were authorised for recently-enlarged schools belonging to the Board:—Winchester-street, Finsbury division, £143 2s. 8d., 400 school places, equal to a cost of 14s. 3d. per head; Hollydale-road, Lambeth division, £264 11s., 400 school places, equal to 13s. 2d. per head; and Ben Jonson, Tower Hamlets Division, £279 4s. 6d., 480 school places, equal to 11s. 7d. per head.

A Local Government Board inquiry was held at Hastings, on Friday, before Mr. Robert Morgan, C.E., into an application of the town council for sanction to borrow £3,300 for works of sewerage in St. Andrew's district, so as to prevent the frequent floods; and £16,900 for laying out the new park and for the formation of new roads connected therewith. Mr. Andrews, the surveyor to the town council, gave evidence showing the desirability of the proposed works.

Mr. John Braithwaite has been re-elected surveyor of Lower Darwen.

New schools are about to be erected by the Ore School Board from the designs of Messrs. Jeffery and Skiller, of Hastings, architects to the board.

Intercommunication.

QUESTIONS.

[5716].—**Imperial Hotel, Torquay.**—A client of mine wishes to build an hotel somewhat upon the plan of the Imperial, at Torquay, which I am told was illustrated in some of the building papers about the year 1866. I should be greatly obliged if any of your readers could inform me what date it was published, or where I can obtain a plan.—J. A. C.

[5717].—**Deals.**—Can any of the readers of the BUILDING NEWS give me some information on the following subject:—I am working under a specification which specifies second Petersburg deals to be used for joists, common rafters, &c., but in the description of materials at the commencement of the specification it states that all timber is to be free from sap, shakes, &c. Now the clerk of works is interpreting this literally, and entirely ignores that second Petersburg are not free from sap. The question is, can I be compelled to provide deals free from sap, &c., or is the law on my side if I refuse to supply any other kind than that specified? I did what other competitors no doubt did when making out their tenders—viz., allowed for second Petersburg only.—W. B.

[5718].—**Billiard Tables.**—Will any of my fellow readers kindly inform me of a good treatise on billiard tables? Also one giving all the different sizes and full particulars of same. Please state price.—C. P. L.

[5719].—**Wooden Verandah.**—Will some one give me a few practical hints about a verandah in wood?—H. R.

REPLIES.

[5699].—**Driving Sewer Headings.**—I am much obliged to Mr. Welch for his reply to the above query. May I further trespass on his kindness by asking for information as to the method employed for getting the dirt out of and back into the heading, especially when it is of considerable length? Is there any great difficulty in filling in after the pipes are laid on account of the limited headroom? Also, is there much trouble in getting the timber out in moderately good ground?—RESURON.

[5707].—**Haslingden Flags.**—In reply to M. Watson, I may say the flags and setts he mentions come from the localities mentioned in the specification, which are on the line of railway from Bury to Bacup, and very near to Manchester. The stone is of a good quality, bluish in colour, and very hard. I should say it is quite as good, if not better, than York stone.—J. A. C.

[5709].—**Perspective.**—In reply to "Interior," it may be best to imagine how practically to obtain a few leading lines—say, of the interior of a church, after which the other lines could easily be filled in. First, it may be as well to remark that the best and quickest way will be to geometrically draw the plan of the portion beyond the picture plane to the same scale intended for the perspective. Next draw on plan a centre line longitudinally through the nave and chancel. Next draw on plan a line at right angles to the former, and to exclude as much of the building as is not to appear in the picture. The position of this line will require to be determined according to the design as to whether there are aisles or transepts to span or otherwise, and as to the character of the nave itself, which if very long and narrow, would not be fairly conveyed unless much length were included in the picture by the trace or plan of the picture plane, and, moreover, the more the latter includes the greater the tendency towards sublimity in the picture so far as general effect is concerned, but the less the detail of arches to nave and clerestory windows can be developed. Next comes the distance of the base line on the geometrical plan. This must also be drawn at right angles to the longitudinal axis, on plan, and as it contains the station point or point of sight somewhere in its length it must be placed at such a distance from the plan of picture plane when considering the extremities of the latter at each end to be identical with the horizontal limits of the intended picture, that any two lines drawn from the extremities of the plan of the picture plane to any assured point in the base line and considered as the point of sight, shall not contain at the point of sight an angle of more than 60°—i.e., 30° on each side of the plan or trace of the central plane, which is an imaginary vertical plane intersecting with the axial vertical plane (which would pass through the centre of the ridge or ridge rib) at the extremity of the chancel or apse or as the case might be, and its other end would intersect or be identical with the station point wherever the latter may be placed. It could be placed in the axial plane, when it and the central plane would be identical, but such would be destructive of relief to the eye and utterly prevent our getting a perspective view of any existing planes parallel with and facing the clerestory wall planes, and being on the same side of the axial plane as the wall planes which they face. It is therefore necessary and customary to make the central plane and the axial plane contain several degrees, and the point of sight consequently to the left or right of the intersection of the axial plane and the base line which allows the opportunity of fairly depicting the details of the arches, windows, &c., on one side, and gives a good view of the roof. With respect to the base line, which, as we have seen, contains the point of sight, it may be so determined as to be much more distant from the picture plane, and which would much diminish the angle subtended by lines from the point of sight in such line, and which would give more grandeur of idea as to the building at the expense of not so fully developing the detail. Then with respect to drawing the perspective, it may be well to recollect that the picture is practically the converse of the geometrical plan we drew, having the picture plane as a neutral plane between the two; that is to say, that all lines at right angles to the picture plane and which on the geometrical plan diverge from the station point, will in the picture converge from the neutral plane—i.e., the picture plane to what is usually called the point of sight, but which might perhaps be more appropriately called the point of distance, and such point of distance or point of sight will be exactly opposite its correlative on the geometrical plan. Now to begin work. Draw radial lines, turn point of sight to the point denoting the plan of each vertical line required to be shown in the perspective. It

will be necessary in most cases to be careful and take the lines seriatim and transfer same by a slip of paper to the ground line of the picture plane on the perspective; then with respect to setting up heights they will be the same scale as the plan, as we are drawing in what we call parallel perspective (though to be correct the central plane could not then be oblique as we have it). The heights can be set up from the same scale anywhere along the picture plane, but in practice will usually be measured on the very vertical lines requiring them. On this system the perspective will show equal halves to any vertical plane being parallel to the picture plane and bisected by the axial plane, and their intersection carried to the picture plane by a line to point of sight and then transferred by slip of paper to perspective. It will frequently be useful to adopt proportional lines of heights for special cases within the picture plane in order to save drawing and confusion of lines, and it is also well to place the horizontal line—i.e., the height of the spectator's eye, high as he might be elevated. Truth will prevent our adopting a point of sight which, through the existence of a west wall, would have the visual rays intercepted; but where a western gallery exists there would be an excellent and possible place for a station point, and the horizontal line would be drawn at 5ft. above the gallery floor on which the spectator would stand. Then having a high horizontal line we shall have a good view of the building on four sides instead of three—viz., the roof, the side walls, and the floors and benches if shown, which will truthfully enhance effect and the better show bases to columns, &c. Having a good perspective floor view by very fine firm pencil lines, and the portions of same requiring *pro tem.* to remain on the paper, being drawn firmer and blacker, we can complete on plan in perspective the plan of whatever we require to set up vertically, and the sections of moulded principal rafters and of transverse ribs and of diagonal ribs can be drawn on plan in perspective and carried up to top of abacus and then drawn to their proper straight or curved lines as the case may be, bearing in mind that all portions of circles in roof ribs, which are in vertical planes parallel to the picture plane are seen their real form, and may be drawn with the compasses; but as it is said that there is not a really straight line in the Erechtheum, and in a really artistic building there should not exist a rigidly correct geometrical line either curved or straight, therefore the segments will be best drawn easy with compasses having needles. If drawn by hand alone they cannot average the true curve, and on the building nothing but the average of the true curve would be tolerated, and we should not depict what is worse, as a segment drawn by hand would compare unfavourably with one drawn by the compasses, as we cannot draw like Giotto. Diagonal ribs should be divided from the geometrical plan, on which they would be described as turned down on their horizontal axes, drawn on the paper, and their points projected to picture plane transferred to perspective. The height to each division will be taken from the drawing of curve on the plan. Intermediate ribs and liernes can be projected on the plan in a like manner, and transferred, &c. It would prove convenient in such cases to use thick tracing paper, as plan upon plan, again and again, must be drawn to obtain the necessary points, and any undue attempt to dispense with their necessary production must injure and tend to muddle and worry the paper, or else detract from the effect which the faithful drawing in perspective of the correct curves would produce; because a curve not a true one (on the average) must be a deformed curve, and such can be no more desirable in perspective than in geometrical drawing, and would never be tolerated except that the general beauty of the interior, together with colouring or etching, tends to conceal it.—HENRY AMBROSE.

[5711].—**Cricket Pavilion.**—Amongst the best and most favourably noticed drawings submitted in competition for laying out Roundhay Park, Leeds, was a very beautiful design for a double-fronted cricket pavilion, the author of which was Mr. Stewart, of Wool Exchange, Colman-street, City. I believe it was erected somewhere near London, but I am not certain.—C. MURFORD.

[5712].—**Lift.**—If "Hoist" will put himself into communication with us we shall be happy to give him any information he may require. An intelligible description would occupy too much of your space.—A. S. AND S., 43, Leicester-square.

[5714].—**Deficient Quantities.**—In a book entitled "A Legal Handbook for Architects, Builders, and Building Owners," by Edward Jenkins and John Raymond, barristers-at-law, dedicated by permission to the Royal Institute of British Architects, and published by King and Co., 12, Paternoster-row (5s.), your correspondent, "W. D. B." will find the following on page 73:—"When the contract consisted of a tender to execute certain work contained in specifications and quantities made out by the employer's surveyor and an acceptance of that tender, it is held that the builder could not recover as for extras for an excess of work performed in consequence of an error in the quantities." For a case where this point was thus settled, we are referred in a footnote on the same page to Coker v. Young, in Foster and Finlason's Nisi Prius reports. This case was tried in 1860. Mr. Jenkins, one of the authors of the "Legal Handbook" referred to, and whose address, I believe, is 5, Paper-buildings, Temple, would be able to give "W. D. B." further particulars.—NICHOL FILIUS.

STAINED GLASS.

STOW-ON-THE-WOLD.—The five-light west window of the parish church of Stow-on-the-Wold has been filled with stained glass from the manufactory of Messrs. Wailes and Strang, of Newcastle-on-Tyne. In the tracery are seven angels holding scrolls containing portions of the passage in Revelation—"Holy, holy, holy, Lord God Almighty," &c. The middle portions of the lights are filled by full-sized figures of Moses, Isaiah, Jeremiah, Ezekiel, and Daniel; and in the base of the window are subjects from the life of Moses.

The Lancaster Town Council are about to erect new markets from the designs of Mr. John Thompson, architect, of that town.

LEGAL INTELLIGENCE.

INSECURE SCAFFOLDING.—The Judge of the Sussex County Court district lately heard a case at Brighton, in which a plasterer claimed £50 damages, arising out of an injury received by the falling of a scaffold while he was working on it, said to be due to the negligence of the defendant, his employer, in having it improperly erected. It was shown that a scaffolding had been erected by a man who was not accustomed to such work, and on a bag of cement being thrown out of a window about 3ft. above the scaffolding on to it, it gave way, and the plaintiff was precipitated from it, and broke his leg. Plaintiff said that the scaffolding was 30ft. long, that it had only supports 3in. square, in the middle, and one at each end. The judge said: This is only one of many instances in which injury has arisen through scaffolding being improperly erected, and I am of opinion that all such erections should, like plans, be subject to the approval of some official appointed by the local officials. I know that when a large church was being erected here some time ago, the scaffolding, which was of immense height, was built by a labourer, who knew but very little about such work, and long ere the work was completed, the scaffolding had swayed over, and was only supported by the building, which was in course of construction. One tradesman who was engaged in the work objected to his men using the scaffold, but others were not so considerate. Very frequently are the scaffold holes too slender for the purpose for which they are used. The existing state of things is a crying evil, and should be remedied. Those engaged in the erection of buildings should be protected against employers who are not considerate, as well as those who are to occupy the buildings when completed. In these days of contracts, we cannot exercise too much official supervision.

Our Office Table.

SIR SIDNEY HEDLEY WATERLOW has a pretty little controversy on hand with the Duke of Richmond and Lord George Hamilton. Sir Sidney is chairman of St. Margaret's Technical School, Westminster, of which the head master is Mr. Goffin. Mr. Goffin is charged by the Science and Art Department with having obtained improper access to the examination papers which were to be used for the examination of his pupils last year. The examiners found, when they came to look at the answers, what they thought was evidence of mechanical answers learnt by rote. They made inquiries, which revealed that just before the examination Mr. Goffin had drilled his children in eight of ten questions on their papers. Further, they discovered that Mr. Goffin had, through the carelessness of the secretary of the school, had the papers for some time in his possession. There was a visit to the school. Mr. Goffin denied the charge, but, without affording him any opportunity of rebutting the evidence, the department refused again to accept him as an accredited teacher. It was mere waste of time for Mr. Goffin to appeal to be heard. His managers lost their trouble in writing on his behalf. The department had made up its mind. Sir Sidney and his colleagues being opposed to the appearance of injustice, refused to dismiss their master unless they heard the evidence against him. The department refused to give the evidence or to rescind its order. So the case stands. Mr. Goffin will shortly be made the subject of a Parliamentary debate.

The Southampton Town Council have, it appears, agreed to do the least possible in the way of providing public offices, and have referred the question to a committee who are empowered to call in an architect, if necessary, to consider and report upon the adaptation of the existing premises to Corporation and Post-Office requirements. If there are no means to build new offices, of course the patching up of the old premises at the least expense is the only sensible course, though in such case we cannot see the good of calling in an architect when the town have already plans prepared by their own consulting surveyor. As Mr. Lemon's services are included in his salary, why go to any further expense about what must after all be a mere makeshift for a few years? Such a procedure seems to us an unnecessary waste of time and money, and not flattering to their surveyor. The most amusing part of the affair is that the question has been made a party one and a test for electioneering purposes, while the most expensive mode of dealing with the old premises has been suggested.

THE BUILDING NEWS.

LONDON, FRIDAY, APRIL 4, 1879.

THE SOCIETY OF BRITISH ARTISTS.

THE pictures at the Suffolk-street Gallery of the above Society, if they do not quite equal former displays in some of the higher qualities of painting, maintain a fair average of excellence in landscape and *genre* subjects. The large room is adorned by works of some well-known artists, of whom we meet with the names of Goodall, Woolmer, Caffieri, Lee, R. Redgrave, Cox, Alfred Cole, Sir J. Gilbert, Bromley, Ludovici, W. H. Gadsby, Gerardin, Cobbett, J. Burr, Girardot, Bartlett, Clint, Hines, and others. To come to the most striking works first, we may place Mr. Caffieri's "Music Lesson" (13) in the front rank as a charming example of effective drawing and colour. A group of young ladies round a grand pianoforte are taking their music lesson in a spacious and richly furnished room, draped on one side with dark curtains. The window opening in the latter, through which a peep of green leaves is obtained, the light tints of the silk dresses—blue, pink, and buff—the blending of the colours and the truthful perspective, make up a very pleasing subject. Vigorously painted, yet delicate in tone, the picture is seen best at a moderate distance. One of the finest studies in forest life is "The Oak and Birch" (92), by Mr. Fred. Hines, the massive trunk and foliage of the oak and the contrast with the light feathery spray and silvery stem of its more delicate companion the birch, are admirably painted. Excellent as a transcript, it possesses a higher meaning in its contrastive power, while the manipulation is nearly perfect. A more impassioned piece, persuasive and emotion-moving in its direct appeal to human sympathies, is Mr. J. Burr's "Words of Comfort" (125). The handling is energetic and massive, and the depth of tone in keeping with such a theme. Mr. A. J. Woolmer contributes one of those epic landscape subjects for which he has a decided penchant. It is entitled, "The Primeval Forest: A Leaf from the Stone Book" (148). The artist has painted a grand old oak springing up amidst a scene of luxuriant vegetation and animal life, such as one may imagine to have existed in the primeval forest. The idea is poetically worked out; the dark grotto, and the grove beyond, with the trunks and branches of trees against the bright sunlight, the serpent entwined in the oak branches, the fowls of air and water, combine to present a picture quite antediluvian. Mr. Woolmer is a vigorous painter of nature in its grander moods. The luminous effect upon the trunk and foliage of oak, the brook below, and the water from the rock at the sides show a wonderful mastery in the opaque colouring of the high lights and the transparent or glazing tints over the deeper or darker portions of the picture. The scale of tone and the vigour of touch are no less remarkable. Another picture of some merit is No. 157, "Tired Out," exhibiting an incident that tells its own tale. The artist, Mr. A. Dixon, has covered a large canvas, fully sensible of a well recognised mode of enlisting attention. The subject chosen is a railway-carriage compartment occupied by a young soldier, a mother with her two children, both asleep, and a young girl attired in sombre dress, who is looking out into the dark night with a careworn, anxious, and tired expression on her face. The gloom of the carriage and the darkened features of its occupants, worn with fatigue and ennui, are well depicted. A few fine landscapes are to be seen.

We notice No. 181, "A Scene in North Wales," by Mr. E. J. Cobbett, remarkable for the cleverly-painted gleam of sunshine over some rugged uplands; the figures are less happy; No. 189, "Pastimes and Times Past," by Mr. W. Holyoake, boldly painted, yet stiff in execution; "Eagle's Crag, in Borrowdale," by Mr. J. Peel, a grand mountain piece, in which the colouring and effect of sunshine and atmosphere are rendered with considerable skill; No. 163, "Up Stream," by Mr. Stuart-Lloyd, clever in the handling of feathery foliage; and two pleasing pieces, Nos. 103 and 104, the first, "Temple Reach, Hurley," by Mr. A. de Branski, and the second, "The Last Swallow of the Season," by Mr. W. Gosling. The latter is a view of the Thames at Bolney, and the delicate drawing of the trees in their autumnal dress contrasts with the freshness of the piece above. One of the largest architectural pictures is Mr. Wyke Bayliss's "Interior of the Church of St. Remy, Rheims" (164). The artist has sought to embody the sentiment of the poet conveyed in the "Golden Legend," from the stanza:—

"Shafts of sunshine from the west
Paint the dusky windows red;
Darker shadows, deeper rest,
Underneath and overhead;
Slowly, slowly, up the wall
Steals the sunshine, steals the shade."

The red glow of the western sun and the misty stealing shadow over the arcades are painted with effect, but the perspective of the arcade is certainly faulty, and the detail carved string courses and capitals are coarse and lumpy. Compositions representing everyday-life and manners are, as usual, plentiful. No. 42, "Pensioners' Pensioners," is a homely incident told by Mr. A. W. Bayes with much pathos and feeling. The old women in the hall feeding sparrows are thoroughly characteristic of the comfortable hospital, and the expression on their faces betoken the interest they take in their kindly office. In grouping and colour the piece is admirable. Mr. Bromley, in the "Fruit Seller" (38), shows a Spanish brunette sitting on some steps with her fruits, her dark eyes turned askance. The colouring is bright and genial, and the execution clever. Sir J. Gilbert, R.A. (30), in his usual vein, depicts an incident in "Tristram Shandy," in which Corporal Trim questions Uncle Toby's paper projects. The scene is cleverly depicted, and the characters of Sterne's humorous story well sustained, though the drawing of table is poor and the red coats a little too harsh. Mr. W. H. Bartlett's portrait occupies a conspicuous place; it is of a young lady in sage-green, sitting in a red armchair, looking at an album. There is rather a meaningless intention in the piece, though the work is characterised by solid handling and depth of tone. No. 100, "Finishing Touches," by Mr. Watney Wilson, is the picture of an old Jew trimming his beard. The old man's face and hands are very transparently painted, and the chiaroscuro and execution leave nothing to be desired. The faces of the old man with gout, the wife, and the little girl in No. 178 "Kind Enquiries," are natural and carefully painted, and the artist, Mr. Hayllar, sustains his reputation as a truthful renderer of everyday life. Perhaps one of the most amusing of *genre* subjects is "Old Crabby" (176). The artist has caught the true feline expression of temper in the ears and eyes, while the intruding pugs are cleverly rendered. Mr. Ellis's "Forage Party" is forcible in colour, the geese and the grass, trees and hedge are painted in a vigorous and telling manner. One of the most remarkable pictures in the large room is by Mr. J. Morgan, entitled (No. 153) "French and English." Two parties of boys are trying their strength by pulling at a rope, one of the groups being numerically double the other. The smaller band has ap-

parently the advantage. Two urchins on the other side of a fence are, in a spirit of patriotic bravado, deriding the large party. We are struck no less by the expressive features of the boys engaged in the "tug of war" than by the gestures of the urchins who are lookers-on of the struggle, and the colour and finish of the landscape. In the north-west room one or two pictures attract attention. Mr. J. R. Ashton, in "Check," shows a game of chess. The two players are obviously adepts; but we pass the obvious plot to remark upon the bold and solid manipulation, the dark setting to the faces and chess-men, and the clever colouring. "The Abbey Trees" (173), by Mr. Stuart Lloyd, is a picture worthy of the artist's reputation as a painter of an unconventional school. There is a velvety softness in the background and foliage, and the flowering grass is characterised by a dexterity and softness of manipulation almost realistic, putting us in mind of those pictures reproduced through the agency of the camera obscura. "Learned Leisure" (475), by Mr. F. S. Muschamp, is a sentimental conceit—lady in golden-coloured satin sitting under a window of painted glass. The colours, the deep red couch and the dress, produce a rich cabinet picture. A fine landscape meets us in 456, entitled "Where the Wild Thyme Blows," in which Mr. Grace has realised, in his usual broad manner, the rounded masses of foliage and blue distance. Equally good, as a reminiscence of old church days, is Miss Jane Humphrey's "O, come let us sing unto the Lord!" (491), and Mr. Goldingham's jesters, called "One Fool makes many" (462); while Mr. W. Henry's view of "Canal and Civic Hospital, St. Mark's, Venice," is an architectural subject, well painted.

No critical observer can fail to notice the almost unanimous return, among artists of figure-subjects, to the costume of the last century, and that which preceded it. Periwig and knee-breeches, the rosettes and court-dress of a former generation—even Regency dandyism—are becoming the fashionable habit among artists who once were wont to clothe their figures in ancient togas, or to wrap them up in cloaks. In this respect painters are keeping architects company, and it certainly would be rather an anachronism to introduce modern dress into a room of 17th century style and furniture. In such guise, anyhow, we have several pictures. Mr. J. Rick's "Evil Beginnings have Bad Endings" (424) is a clever subject, though, we must confess, a trifle obscure in its meaning. An old man in wig, doublet, and surtout, is playing whist with a young man—it may be a son—while above the latter, in the corner of room, is a mirror, in which is reflected the hand of cards of the latter. The faces of the players and the accessories are admirably rendered. Singularly faulty in drawing is Mr. Hawkins' allegorical subject, "The Progress of Time, representing the Sun-dial in Aldbury Churchyard, Herts" (425). The figures are crudely painted, and there is a general want of scale. A forcible picture is No. 403, "Guilty, or Not Guilty?" by J. Faed. The prisoner's scowl, as he is brought in between two soldiers, is a masterly piece of expression, and the colouring is equally good. We can only glance at Mr. Ludovici's "Dancing Class" (228), depicting a row of girls in coloured dresses being taught by a master; it is a clever, vivid piece of colour, admirable in drawing, and like all this artist's works, displays an energetic style of manipulation thoroughly characteristic. No. 360 is a grand Alpine piece, "Morning in the Alps"; the pine and the sunlit peaks produce a striking ensemble. A few others we note by number as skilful renderings of everyday life; such are Nos. 292, 256, 240, 299, 210, 215, 386, 383, 532. Mr. J. Ellis's drawing, 505 is a vigorous handling of sea and shadow,

though too rough and dauby in its near effect to please the ordinary run of picture fanciers. No. 504 is a clever figure subject, and Nos. 506, 512, 517, 530, and 538, are also striking pictures.

The water-colour subjects do not come up to previous exhibitions, and our space will not permit us to individualise the best even of these. Some of the subjects are singularly feeble, and a few sensational in style and execution. In this class we place Nos. 553 and 725. The view of St. Wolfran's, Abbeville (584), is a large subject, spoilt by the inky tone of the noble front, and the drawing suffers from crudeness and lack of aerial perspective. Mr. D. Law sends, as usual, a few conscientiously-drawn landscapes, 724 being the boldest. No. 776 is clever in its foliage and distance, and the hazy effect over mountain; 570 is a sunny piece, and 571 very natural. For truthfulness of colour, and simplicity and breadth of execution, Nos. 601 and 602 are, without doubt, exceedingly conspicuous among so many attempts at artificialities of style. They remind us of some of the better works of Pyne or Peuley, depending for their effect on local colour and transparent shadows, broad in handling, and without that painful, affected manner noticeable in many works in the same room. Nos. 627, 648, 699, 694, 625, 624, 622, exhibit skilful drawing, and come within the class of genuine water-colours.

THE MAINTENANCE OF MACADAMISED ROADS.*

ROAD making and maintenance is an art that has been pretty much left to tradition, the most experienced roadmakers having furnished little or no written instructions. Since the days of McAdam and Telford, the literature of road construction has been very scantily added to, and the secret of good roads has more or less remained in the keeping of turnpike, town, and country surveyors. Mr. Thomas Codrington, M.I.C.E., the general superintendent of county roads for South Wales, has in some measure supplied the want by publishing a treatise on "The Maintenance of Macadamised Roads," giving the result of experience and observation relating to the systematic management of roads. The author brings considerable knowledge and observation to the task, mainly the result, it would appear, of having the superintendence of a large area of road maintenance. The conclusions of foreign engineers have not been overlooked, for we find the "Annales des Ponts et Chaussées," and other authorities, have been consulted, and many valuable experiments with reference to the bulk and weight of broken stone for metalling, the "draught" of vehicles, &c., are given. In the last-named matter, Morin's and Dupuit's experiences are recorded, besides those of Sir J. Macneill and other engineers. The author, agreeably to the best experience, lays great stress on the necessity of good drainage of road surface and subsoil. It is now generally agreed that attention to these points is absolutely essential to economy of maintenance, and that, though the first cost may be large, a well-drained road is the cheapest. Some useful hints as to the various modes of cutting drains for the foundation of a road are given which would have been more practically useful to a large class if illustrated by a few sections. In speaking of roads in open level districts, the author says the field side of the fences, where the width of land taken is limited, is the best place for the sunk side-drains or ditches. In cuttings, the drains are best under the "water-table," or side channel, cut about a foot below the

formation surface, and filled in with rubble-stone up to the road materials. In sidelong ground, catchwater drains should be provided, to intercept surface-water from the high ground in addition to the covered drains. Sometimes, besides the lateral drains, cross, or "mitre drains," are necessary to be cut, meeting in a V in centre of road, and discharging into the side ditches. The author says a fall of one in a hundred is sufficient for these drains, which may be cut in the formation surface about 6in. deep by 12in. wide, filled in with broken stones or pipes, or, better still, small box-drains, consisting of dry side walls and a cover-stone. Speaking of the cross section of a road, upon which much has been said, Mr. Codrington advocates a moderate degree of convexity, just sufficient, in fact, to throw the rain-water off freely. The evil of a too convex contour has been found to be the tendency of the traffic to use the crown of the road entirely, as the only part where the vehicles can run upright, the consequence being that a hollow track is formed which retains the water, and the road wears unevenly. In flatter sections a more even wear is the result. Telford adopted a flat elliptical curve, more convex in middle than at the sides; Walker, a section composed of two straight lines, joined by a curve in the middle, having a fall of 1 in 24 at the sides, but, practically, a segment answers the purpose, the main consideration being regularity of section and evenness. The author observes:—"A fall from centre to the sides need not be generally more than 6in. on a road 30ft. wide, and should never exceed 9in.; for a road 18ft. or 20ft. wide 3in. or 4in. is enough." Roads with gradients need less curvature of section than level roads, though this rule is not always attended to. The curvature of section may be given by forming the bed of the road with a fall from centre, or by diminishing the thickness of road coating towards the sides. Telford used to form his road-bed level in cross section, giving the convexity by diminishing the bottoming of gravel at the sides. A carefully-laid bottoming or pitching of stones on edge, consolidated by beating with a large hammer, is better, we believe, than Telford's plan of forming a regular pavement of stones. The method of McAdam, who dispensed with an artificial foundation, and placed his broken stone directly on the native subsoil, has generally been followed, however, by modern road-makers, though we find the author inclined to disapprove of the practice. We are disposed to think a flexible road substratum the best both for wear and traffic, if inequalities are filled in; we also differ from the author in thinking a uniform thickness of metalling the best; it is better, we think, to cut the formation surface to a slighter curve, to give a thickness of metal diminishing at the sides. Concrete foundations, introduced by Macneill, are, perhaps, better than pitched where much traffic exists, and lias lime concrete, 12in. thick, has been used under the macadamised roadways of the Victoria and Chelsea Embankments. When set, 6in. of granite were laid over it in two courses well rolled. In speaking of broken stone roads, the author says a thickness of 3 to 6in. should be laid on first, choosing dry weather for the operation; when consolidated, or partly so, under the traffic, and the ruts filled in, other coats may be added until the thickness is reached. "The layers after the first will work in better if laid in wet weather." . . . "It is best to give a new road a stronger coat than would be enough for an old road under the same conditions of traffic and situation, and it is seldom advisable even on the best bottom to make a new road less than 6in. thick. On a well-drained bottom this will make an excellent road sufficient for a considerable country traffic. McAdam considered that 10in. of

well-consolidated material was enough to carry the heaviest traffic on any substratum, experience has proved this to be true with a well-drained and properly kept road, and even in the macadamised streets in London. It is seldom necessary to give more than 8 to 9in. thickness, and it is better to add gradually by successive coats of metalling to a road made at first rather too weak for heavy traffic than to give the whole thickness at once." The remarks on water-tables, rolling, &c., will be found of practical interest, and we pass them over with the remark that the author recommends a binding of limestone detritus or road scrapings when the road materials are siliceous, and sand for limestone materials—chalky or clayey binding being avoided. As to cost of macadamised roads, the author says, with materials at hand, a good road may be formed and coated for 1s. or 1s. 3d. per square yard, and a London street constructed in the best manner, with 9in. of Guernsey granite, may cost as much as 6s. to 7s. per yard. The suggestions on road materials, stone breaking by machinery, and the cost will be found useful to surveyors generally. The "composition of road coating," or the space taken up by broken stone of different sizes, is discussed in detail, and numerous experiments and results are quoted, into which we cannot enter here. If we take the author's examinations, it appears that no matter what the strength of road, or its thickness, or material, or traffic, the proportion of mud that can be washed out, and which forms the binding material, is about the same. Some interesting experiments made by the author are described, for determining the effect of heavy loads on wheels in breaking the road coating; which only prove the great damage done to roads by heavy loads carried on narrow tires, and that considerable wear is due to this cause alone. The chapter on "Measurement of Traffic and Wear" exhibits the French mode of finding out the amount of wear; but there are so many factors at work that it is difficult to draw any safe conclusion from the experiments. From numerous observations it has been found that about 100 cube yards per mile per year is the average consumption of good roads, though in the metropolis six times that quantity of granite have been used annually per mile. In spreading road materials on old roads it is suggested that they should be laid on in small quantities where hollows or weak places occur, or where necessary, to preserve the cross section of the road, and this patching should be done with care, not in square patches, the angles of which are wasted or got knocked away, but in oval or circular forms, according to the shape of the hollows. Autumn and early winter are the best times for repair. The custom of loosening the road surface with the pick is thought undesirable in weak places if the border round the patch be slightly loosened to give the new stones a hold.

We cannot refer to many other useful hints given under this heading, perhaps one of the most important sections in the book, as the economical maintenance of a road largely depends upon the manner it is patched and the removal of the detritus resulting from the wear of material. Regarding the latter, the author advocates a thorough removal of superfluous mud, so as to keep the road hard, though he acknowledges that scraping may be carried too far, by removing stones of a size which would be useful in the road and increasing the wear of it. Bayley's hydrostatic vans for watering are recommended as saving, and Mr. W. J. Cooper's patent for mixing chlorides of calcium and sodium with the water is spoken of, though the results are not favourable to their use. Some useful data as to cost of labour, and its proportion to materials, are given, from which we gather that the cost of manual labour is generally from 30 to 40 per cent. of the

* The Maintenance of Macadamised Roads. By THOMAS CODRINGTON, M.I.C.E., F.G.S. London: E. and F. N. Spon, Charing Cross.

combined cost of labour and material. In South Wales the manual labour is from £7 4s. to £9 1s. per mile of road per year, or from 2s. to 2s. 10d. to a cubic yard of materials laid. In London the cost of maintaining macadam roads is from 2s. to 3s. 6d. per square yard annually. Mr. Codrington does not compare the cost of wood or asphalt with macadam, though there is a decided difference in favour of the first. Generally, it is shown by the author that no real economy is to be gained by saving labour in surface-work and in the removal of the worn-out materials from the road. The advantage of having men in charge of certain sections of a road is pointed out, as they become familiar with the peculiarities of them and begin to feel an interest in their labour. The road-surveyor's duties are discussed, and the author counsels care in the preparation of estimates and in accounts of the actual expenditure on different roads year by year. The expenditure on repairs should be kept distinct from cost of management, and the labour on surface-work from that pertaining to materials. We unite in the hope that the New Highway Act will systematise the maintenance of our highways, by requiring the accounts of expenditure on roads to be rendered to the county authority, so that a useful comparison may be established for future guidance. The appendix to Mr. Codrington's book contains forms for annual estimate, accounts, &c., and adds to the usefulness of a guide that will become almost indispensable when it is known.

ARCHITECTURAL MOSAIC.

III.—MEDIÆVAL MOSAIC.—(Continued.)

WE have now described all the principal kinds of Middle-Age work. To speak much of the pictorial design of each school would far exceed our limits; and we prefer the more practical task of describing as much as can now be ascertained of the technical methods employed. The mode of preparation of the materials for glass mosaic was long preserved as a secret art, handed down traditionally among the workmen. Ancient MSS. have however been discovered of late years, which throw some light upon it. From one of these, known as the "Bolognese MS." we extract the following particulars. This MS. was written in the 15th century, in a kind of Italianised Latin, and has been long preserved in the library of a convent in Bologna. The following translation is by Mrs. Merrifield:—

HERE BEGINS A TREATISE ON MOSAIC COLOURS,

And First How to Make the Material for the Mosaics.—Take lead and tin, of each 1lb., melt them together, and calcine them with common salt, until the whole is reduced to powder in a reverberatory furnace, and then melt the mass and add to it its own weight of raw tartar, and reduce it to powder, and mix it again with common salt, and put it in the reverberatory furnace for one natural day. Then wash the salt out with common warm water, and add more salt, and calcine it again, and continue this until it becomes a white calx. Take 7lb. of this calx and 1oz. of calcined bones, and mix all together, and put the mass into a glass pot, melt it and let it remain in fusion for three days, and try with an iron rod whether it is well digested and mixed, and it will be mosaic or white glass, of which you may make all other colours in glass as follows: To 8lb. of the said material put 1oz. of zaffirdi in powder and mix it well with an iron rod, and when it is quite melted, try with a little of it whether it is a good blue; if not add a little zaffirdi, and let it continue liquid until it is of a good colour. Then cast it, and it will take whatever shape you like, but take care of the wind while you are casting it.

Another Kind of Mosaic.—Take 1lb. of crystal glass and put it in the fire, and, when it is red hot, throw it into spirits of wine in which roche alum is dissolved, and so quench it sixteen times, and then pulverise it on porphyry and mix with it three times its own quantity of ceruse in powder. Fill a jar half full with it and cover it and lute it down, and put it in a soda furnace and let it remain there as long as if it were soda, and when it is cold you

will find your material fit to receive whatever colours you like.

To Make a Saffron-coloured, that is Golden coloured, Mosaic.—Take some of the prepared material and add to it 1oz. of the saffron of Mars, and mix with it 8lb. of the prepared white material, and let it stand until it is of a gold colour. If it does not become so, add a little more saffron of Mars, and it will certainly be like gold.

But if you wish to make a red mosaic, put into the white material 1oz. of alcaun (?) and 1oz. of calcined brass to 8lb. of the said material, and it will be red. But, if you wish to make black mosaic, melt 1oz. of iron and 1oz. of tin, and throw powdered sulphur upon it, and it will make a very good black.

To Make Red Mosaic.—Take 3 parts of the white material, 1 part of calx letitie, that is calx of gold, 1 part of ashes of verzie and 3 parts of sal gem in powder; mix the whole well together upon porphyry, and set it to melt in a glass pot in a glass-furnace and let it remain there for four or six hours; then take it out and you will have a red mosaic.

To Make a Rose-coloured Mosaic.—Take 3 parts of the white material and 3 parts of calx letitie, that is calx of gold, and 2 parts of cineris pencholini, i.e., brass burnt and reduced to powder, and 3 parts of sal gem; pulverise the whole together, and do as you did before.

To Make a Pomegranate-coloured Mosaic.—Take 3 parts of the said material, and 1 part of calx solis, i.e., calx of gold, half a part of manganese (?), and 1 part of sal gem, and do as before.

To Make a Blue Mosaic.—Take 3 parts of the said material, 2½ parts of ultramarine azure, and 3 parts of sal gem, and it is done.

To Make a Green Mosaic.—Take 3 parts of the said material, and 2 parts and 2 oz. more of calx of iron, and 3 parts of sal gem, and it is done.

To Make a Chrysolite, i.e., Glass of the Colour of Gold.—Take 5 parts of the said material, 10 parts of calcined lead, 10 parts of sal-gem; put the whole into a furnace together for five hours, and it is done.

The directions given in several other Mediæval MSS. which we have seen closely correspond with the above; but it will be interesting to the practical worker to compare with them the results of a modern chemical analysis which was made some years ago by Professor Branchi, of Pisa, who procured a number of mosaic fragments from Rome and Pisa, for the purpose of ascertaining the composition both of the materials themselves and of the metals with which they were coloured. Several variations appear as the result; e.g.—In the Pisan mosaics the red colour appears to have been produced from copper, while in the MS. it is produced from gold as well as from copper. Again in the blue, which according to the MS. was coloured with "azzurri ultramarini," was found by analysis both of the Roman and Pisan material to be produced from copper; and the green of the Pisan mosaic was produced by copper, that of the MS. by "crocus martis" and sal-gem. Professor Branchi considers that the modern art of colouring the glass is superior to the ancient, and questions whether the old workers were acquainted with the use of oxide of cobalt for blue, which had been said to have been known even to the Egyptians, because the oxide of copper was sufficient for the purpose, and because in the specimens examined by him, when seen by refracted light, the characteristics of cobalt colouring, as pointed out by Bergman, were wanting entirely. The following are the Professor's words on various colours:—

"I observed also that the last mentioned glass (i.e. the blue specimens), preserved, as it should do, its own colour after being pulverised and fused by fire with a small quantity of carbonate of soda, whilst that from Rome passed to an amethystine colour, which the Pisan glass also acquired, although in a less degree, having been both pulverised, mixed with carbonate of soda and exposed to the same degree of heat. Having treated in the same manner the other enamels of various colours and more or less opaque of the mosaic of Pisa, I saw that the red passed to a blue colour, that the purple was changed to an amethystine colour, and that the black became a transparent yellow glass, on the surface of which was an alkaline stratum of a bluish green. Having repeated these last experiments, I obtained from the dark green, light green and purple enamels, results differing from the preceding in the gradation of colour only. From the red I afterwards obtained a

transparent glass of a yellowish green colour, from the black a violet or amethystine glass. These alterations and anomalies, some of which throw light on the nature of the blue glass of the ancients, are to be ascribed to the greater or less degree of oxidation of the metallic colouring matters."

In the oldest mosaics of St. Mark's, according to Sir H. Layard, there are no true reds or purples, owing to the difficulty of their production; and according to Mr. Fergusson there are no reds, or very dull ones only, in St. Sophia; while in other churches of Constantinople, dating before the Turkish conquest, the reds exceed all other colours in brilliancy.

One of the most beautiful features of mediæval mosaics is their *gilding*. A method of producing gilded mosaic, which was known in the old Roman times, and continued for many ages, was to cover a film of leaf gold placed on the vitreous material, with an actual piece of thin glass, and afterwards to unite the whole into one mass by the action of fire. But according to a later and more improved process, the covering material was little more than a "vitreous varnish," scarcely distinguishable from the gold which it protected, except by having a shining, non-metallic surface, and by the resistance it offered to iron tools, and to the action of mercury and nitro-muriatic acid. The probable method by which this extremely thin covering was applied, was that glass or crystal, easily fusible, was reduced to an impalpable powder, which was distempred with water, or with a solution of gum, or of borate of soda, or other liquid, that this mixture was spread over the gilded surface, and that finally the whole was exposed to heat, which fused the powder into a fine varnish, which has resisted not only the above named re-agents, but now, after the lapse of six centuries, appears without the slightest alteration in the same state in which it left the hand of the artist. The best gold-ground mosaic is undoubtedly that in which this covering material is thinnest.

The cement or stucco with which the mosaics were fixed was of the very greatest importance, and each artist is supposed to have had his own secret and favourite methods of preparing it, but according to Vasari it consisted of slaked lime 1 part, pounded marble 3 parts, mixed with water and white of egg. But as this hardened too quickly there was afterwards used a mixture of 1 part of slaked lime with 3 of powdered travertine stone mixed up with linseed oil, and kept stirred every day during use, adding oil as it dried. The following account of the analysis of the cement used in the mosaics of the Duomo of Pisa, made by Professor Branchi, of Pisa, will be of great interest to the practical worker:—

"The cement or bed of the beautiful mosaic of the Tribune of the Duomo of Pisa consists of two thick strata one upon the other. The lower stratum, which is white, tasteless, of a texture apparently homogeneous, soluble in acids, with liberation of carbonic acid, consisted undoubtedly of a mixture of slaked lime and marble dust. Having tested the weight of 2 denari (grammi 2.358) with acetic acid, there remained only silica and yellow oxide of iron, weighing 1½ gr. (grammi 0.085). The superior stratum in which the parallelopeds of coloured glass were embedded consisted of a yellowish mixture somewhat hard, which acquired on lighted charcoal a colour that was first grey and then blackish. The same acetic acid to the action of which I exposed an equal quantity of this layer as of the lower, dissolved the lime with slight ebullition, and left 12½ gr. (grammi 0.613) of a substance of a dark yellow colour, which I found was composed of linseed oil dried, and a small portion of turpentine, and of other resinous matter. The cement of the mosaics of the cloisters of the Basilica of St. Paolo, without the walls of Rome, was composed of slaked lime and brickdust more or less finely pulverised. It was of a flesh colour, unalterable by fire or exposure to the sea wind, and of a taste slightly saline. By means of an analysis, sufficiently accurate for the purpose, I find in the same quantity (viz., 2 denari) that its constituents were nearly as follows:—

	Denari.	Grains.	Grammi.
Carbonate of lime	1	3½	1·350
Pulverised bricks deprived by acetic acid of their calcareous parts	0	11½	0·572
Muriate of soda, earthy muriates, and a little cal- careous sulphate	0	8¼	0·433

By these results I have learned that the grounds of the mosaics were not always prepared in the same manner."

Sir M. Digby Wyatt was of opinion that the ancients probably used for their finest pictures some retarding agent, such as beer or honey, which would tend to keep their cement plastic longer than it would if mixed with water only.

The method of working differed from modern methods chiefly in the fact that the ancients worked exclusively from the front, while many modern mosaics are prepared from the back, and affixed to their places in *plaques* or sections. The surface to be decorated, built of brick or stone, was first rendered with rough plaster, to make a key for subsequent coatings. Then a strong and fine plaster, nearly 1 inch thick, was put upon it. Cartoons or drawings of the subject were either placed within view of the workman as a guide or were drawn upon the plaster itself. The beginning was always made with the most important part of the design, the artist first knocking out with his chisel a portion of plaster corresponding in size to that which would be occupied by a few tesserae. He then selected a piece of the vitreous material of the proper colour, from a tray in which the various colours were arranged. This would be about the size of a circle 5 or 6 inches in diameter and ½ an inch thick. To cut this to the shape and size required he placed it upon a sharp edge of iron, and struck it with an edge tool, exactly plumb with the under iron, and thus fractured it in a direct line between the two edges. An earlier method was to draw a hot iron along the line in which it was desired to make the fracture. When he had thus obtained the small piece he wanted, he took some fresh cement (made of 1 part lime to 2 of marble dust) inserted the piece and pressed it till it was flush with the adjoining plaster, and he could see whether more cement was wanted, and so proceeded till he had finished a face, or some other leading feature, which being done, the superior artist allowed some inferior hand to fill in the draperies and less important parts of the design, while he himself commenced in some other place.

The work thus performed, it must be acknowledged, has often a much greater effectiveness than the extremely smooth work which is performed by the modern method. In the old work there is an endless sparkle and diversity of tint, which frequently contrast painfully with modern restorations in the old buildings. The modern artist has aimed at a fineness, smoothness, and regularity which the old workmen seemed not to care for; and with the result that while the modern work glistens painfully like a single sheet of burnished metal, which some have compared to a "copper cauldron" effect—the old work, having been fixed by the method described, it was impossible to bring each separate piece of glass into an absolutely true place, and consequently they are all seen at thousands of angles, differing some widely and some microscopically, but all reflecting light at different degrees. This it was, combined with a judicious coarseness of execution in work placed at a distance from the eye, which happily gave to the old mosaics that glorious brilliancy and variety which they retain to the present day, and which the modern mosaicist would do well to emulate.

ERRATA.—In our last article, on p. 321, first column, line 28, "remaining" should read "retaining," and in the next column, first line of last paragraph, for "discovered" read "discontinued."

ARCHITECTURAL GEOLOGY.—VII.

IGNEOUS AND METAMORPHIC ROCKS.

IGNEOUS rocks are those which at some time or other during the earth's history have been in a molten condition, from which they have been formed into a solid mass either before the deposition of the overlying sedimentary and fossiliferous rocks, or have been forced up from below in a fluid condition after the formation of those strata which they are often found to pierce through and overflow. Igneous rocks are not always the most ancient, as we find them occurring in nearly every geological age, even down to the end of the Cretaceous Period. Thus, in the Lake district of the north of England, we find a mass of basalt piercing the green slates; they must therefore have been forced up after those rocks were deposited, but previous to the formation of the Old Red sandstone. In Leicestershire the syenite has pierced the coal measures at Mount Sorrel, and has charred the coal through which it has passed, converting it into coke, and rests in a mass above the carboniferous strata. At Dartmoor, in Devonshire, the granite was probably formed during the Permian period, since it has altered the carboniferous rocks with which it has come in contact. In Scotland, where granite abounds and is found in large masses, it appears for the most part to have been the most ancient of the rocks, from the decomposition and weathering of which the sedimentary strata have been formed; but in some cases we find it piercing the overlying schists of the Silurian period in Dumfries and Galloway, the molten granite having penetrated the other rocks in the form of veins.

Porphyry, which consists of compact felspar, in which large and distinct crystals of quartz and felspar are embedded, is undoubtedly of plutonic origin, having penetrated the other rocks in the form of "Dykes," and formed intrusive sheets coinciding with the bedding of the stratified rocks. In North Wales the porphyry is found embedded with the slates and grits of the Silurian period, forming beds of great extent and thickness, and protruding in enormous bosses through the sedimentary strata. In Devonshire the porphyries appear to belong either to the Devonian, Carboniferous, or Permian epochs, having been erupted and spread out in a liquid state over the bed of the sea in which those strata were in course of deposition. In the south of Scotland the porphyry underlies the coal-measures, and rises from under them on the banks of the Clyde, forming the hills of Kilpatrick, Campsie, Kinross, Largs, Gleniffer, and Neilston, as well as the escarpments of Salisbury Crags and Arthur's Seat at Edinburgh.

Metamorphic rocks are those sedimentary deposits which have been so altered and changed in character by the action of heat, sometimes combined with enormous pressure, that their original bedding and the organic remains which they contained have been entirely obliterated, their ingredients being rearranged as crystalline products. To this class of rocks belong many of the granites and other quartzose rocks, mica-schists, slates, marbles, and serpentines. Syenite, which is a species of granite, so named from having been found at Syene, in Egypt, appears as a metamorphic rock in Charnwood Forest, Leicestershire, where it alternates with slates, forming a series of stratified rocks which have been altered by the intrusion of a molten mass forced up from below.

Granitic rocks, whether of eruptive or metamorphic origin, have all a very similar chemical composition wherever they are found, silica invariably predominating, and forming from 67 to 75 per cent. of the mass, alumina being in the proportion of from 13 to 19 per cent., lime from 1 to 3 per cent.,

potash from 3 to 5, soda from 2½ to 6 per cent., and oxide of iron, upon which the colour chiefly depends, varying from 1½ to 6 per cent., the red kinds containing more iron than the lighter coloured. The specific gravity of granites averages 2·66, so that a cubic foot weighs about 166lb., and a cubic yard 2 tons, or about twice as much a yard of coal. The granite of England is only found in large masses in Devon and Cornwall, a few isolated patches of it occurring in Leicestershire, and in the Lake district of Westmoreland and Cumberland. The granite of Devon has been worked on Dartmoor at High-Tor, King's-Tor, Hingston Down, Blackenstone, and at Fremator near Tavistock; it is of a greyish colour and generally porphyritic, having large embedded crystals. London Bridge is built of Dartmoor granite. In Cornwall we find several varieties of granite, which serve as excellent building material; that quarried at the Cheesewring, near Liskeard, is light-coloured, with white crystals of felspar, and has been largely employed in London for building Westminster Bridge, the Thames Embankment, London Docks, the tomb of Wellington in the crypt of St. Paul's Cathedral, and other works. The granite obtained from Penryn and Lamorna has been much used for docks and bridges in London, Birkenhead, and Plymouth, and for fortifications at Chatham and Portsmouth. In the neighbourhoods of Penzance, Falmouth, St. Austell, Lostwithiel, Charlestown, St. Ives, Helstone, and Padstow, much excellent granite is quarried for building purposes. A porphyritic granite has been found at Calstock, Lanlivery, and Luanllian, a block of which was employed to form the sarcophagus of the Wellington Monument in St. Paul's Cathedral.

The syenitic granite found at Mount Sorrel, in Leicestershire, is very hard and expensive to work; some of it has a warm rose tint, which renders it suitable for ornamentation. In the Lake district at Shapfell and Wasdale-Craig, near Penrith, a handsome porphyritic granite is extensively quarried, having a rich reddish-brown crystalline base, with large flesh-coloured crystals of felspar imbedded, and is capable of receiving a fine polish. Patches of granites and porphyry are found in several parts of North and South Wales, protruding through the Silurian and Cambrian strata; it is chiefly quarried for paving purposes.

In Scotland the granitic rocks prevail over all others, especially in the mountainous regions of the northern counties, where they form the basis of the Grampians, extending from Peterhead and Aberdeen on the east coast to Ben Macdui, Ohan, and Fort William on the west. From Ben Nevis the granite is found running northwards through Inverness to the Moray Firth, and occurs in irregular masses about Sutherland and Caithness. It forms a large portion of the Isle of Mull, Arran and other islands on the west coast, and is found in the southern counties of Dumfries, Galloway, Kircudbright, and Wigton, where its veins pierce the Silurian rocks. The principal quarries of Aberdeenshire are in the neighbourhood of Aberdeen, Peterhead, Aboyne, and Inverury; those of Peterhead being chiefly noted for a red granite of close texture and great hardness, which is obtained in large blocks, and is much used for ornamental purposes, as it receives a high degree of polish; it appears to be of eruptive origin. A finely crystalline granite of a light red colour is obtained at Carnegie, and grey granite at Dancing-cairn, Rubislaw, and Tyrbagger, which is considered to be a metamorphic rock of older date than the Peterhead granite. In Kincairdine the granite is quarried about Banchoory, Cove, and Nigg; and in Perthshire at Aberfeldy and Breadalbane. The county of Banff also contains much granite, of which there are quarries at Marnock; and

at Portsoy, on the north coast, Serpentine is obtained for ornamental purposes. In Inverness there are granite quarries at Stratherrick, Fingask near Beaully, and in the island of Berneray. The island of Mull is noted for its beautifully marked granite of a reddish tint, which is highly prized for architectural work, and was employed in the columns which support a portion of the Holborn Viaduct. In the Isle of Arran we find two kinds of granite, one a fine-grained stone suitable for architectural work, and the other a coarse-grained material. A grey porphyritic granite is largely quarried in Kircudbright at Craignair, Creetown, Dalbeattie, and Newton Stewart, which has been much used for buildings and docks about Birkenhead, Liverpool, Newport, and Swansea. In the county of Wigtown the granite is quarried for building purposes at Glenluee and near Wigtown.

Metamorphic rocks abound in several parts of Scotland, being found on the west and north-west of Argyre, and in the counties of Inverness, Ross, Sutherland, and Caithness; they form the lofty mountains of Ben Nevis, Ben Lomond, Ben Ledi, and Ben Lawers, and extend along Loch Tay, Loch Long, and the Caledonian Canal; they are also found at Inverary, Callander, and the Trossachs, Rannoch, Glenlyon, Fortingal, and the Mull of Cantyre. The basis of these rocks is generally a material called "gneiss," which is similar to granite in chemical composition, but differs from it in structure, appearance, and origin, having a laminated arrangement of its particles, and containing crystals which appear to have been worn round by the action of water and confusedly aggregated. It is never eruptive, or found in veins piercing other rocks, and the quartz, felspar and mica frequently alternate, as if the granite had been broken down and rearranged in separate beds of quartz rock, mica-schist, and clay-slate. Gneiss forms the western shores of Ross and Sutherland, and also is found at Culish, near Avoch, on the eastern side of Ross, near the Moray Firth, where it is quarried for paving. Some of the grey granites of Aberdeenshire also appear to be of metamorphic character.

Serpentine is a metamorphic rock, often classed amongst marbles, which it resembles in appearance but not in composition, and is highly prized for ornamental purposes on account of its variegated colours, chiefly red and green, and the fine polish which it is capable of receiving. It differs, however, very greatly from true marble in its chemical composition, being a hydrous silicate of magnesia and containing from 38 to 40 per cent. of silica, with from 34 to 59 per cent. of magnesia, with oxide of iron in larger or smaller proportions, according as the colour is more or less red. It is chiefly developed at the Lizard, in Cornwall, where it is obtained in every variety of colour, and is easily worked and polished. The green Mona "marble," found at Holyhead, in Anglesea, is also a serpentine. This material is also worked in some parts of the north of Scotland for ornamental purposes.

Marble, or crystallised carbonate of lime, must be included among metamorphic rocks, as it is generally a limestone which has been altered and crystallised by the influence of heat. In England the marbles are chiefly found in the Old Red Sandstone or Devonian strata of Devonshire, and in the Carboniferous Limestone of Derbyshire. The marble quarries of Devon are extensively worked, since blocks of considerable size and great beauty of colour can be obtained from them; those found near Plymouth are generally grey, with white and yellow veins, red marble being also procured in smaller quantities. Red marble is obtained near Totness, and green or rose-coloured marbles at Kitley Park. Black and white marbles are quarried near Bury Pomeroy, and also in some of the northern parts of the county. In Derby-

shire marbles of various colours, as black, blue, grey, and russet, are procured about Ashford, Allport, Bakewell, Buckland-Holow, and Derby. Marbles are also found in almost all geological periods, and wherever igneous rocks have come near enough to limestones to produce crystallisation. Thus we have the Purbeck marble of the Upper Oolitic period, which is a fossiliferous limestone, and has been partially crystallised without obliteration of the fossils; the marble of Carrara, in Italy, has also been shown to belong to the same epoch. In the Wealden we find a hardened limestone which can be polished, and is known as Sussex marble, being locally used for decorative purposes.

Slate must undoubtedly be classed among metamorphic rocks, as, although its chemical composition resembles that of ordinary clay, yet it has been so altered by pressure and heat that all its original bedding and fossils have been obliterated, and a new stratification, termed "cleavage," introduced. This material belongs chiefly to the Devonian and Old Red Sandstone series, or to the Silurian and Cambrian rocks, which were described in a former article. The following summary will place before our readers the order in which the several geological series follow one another, and the kind of building materials that each of them yield, as well as the localities in which they are chiefly developed:—

Geological formation.	Building Materials.	Localities.
Tertiaries	Sand, gravel, clay, brick-earth, cement-stones	Thames Valley, Middlesex, Surrey, Essex, Herts, Sheppey, Hants, Dorset, East Yorkshire, West Lancashire.
Chalk	Lime, whiting, flints, building stone	East Yorkshire, Lincoln, Norfolk, Cambridge, Herts, Bucks, Oxon, Berks, Wilts, Dorset, Hants, Sussex, Surrey, Kent.
Gault	Clay for bricks, drains, tiles, terra-cotta; occasionally building stone	Cambridge, Oxon, Berks, Bucks, Norfolk, Wilts, Dorset, Isle of Wight, Kent.
Greensand	Sand, gravel, freestone, sandstone, limestone, rag	Surrey, Kent, Beds, Berks, Sussex, Dorset, Wilts.
Wealden	Clay for bricks, tiles, &c.; sand, sandstone, limestone	Sussex, Surrey, Kent, Dorset.
Oolite	Limestone for lime and building, marble, flags, slates, clay for bricks, &c.	Portland Island, Dorset, Wilts, Oxon, Bucks, Northampton, Rutland, Lincoln, North-East Yorkshire, Somerset, Gloucester.
Lias	Hydraulic lime, building stone, clay for bricks, &c.	North-East Yorkshire, Lincoln, Leicester, Northampton, Oxon, Worcester, Warwick, Gloucester, Somerset, Dorset, Glamorgan.
New red sandstone	Sandstone and limestone for building, flags, landings, blue and red bricks, tiles, drain pipes, &c.	Derby, Leicester, Stafford, Warwick, Worcester, Yorkshire, Lancashire, Cheshire, Northumberland, Cumberland, Gloucester, Somerset, Salop, Devon.
Magnesian limestone	Lime, building stone	Yorkshire, Durham, Notts, Derby.
Coal measures	Sandstone for building, flags, landings, slates, firebrick, clay for bricks, tiles, terra-cotta	Yorkshire, Lancashire, Durham, Northumberland, Gloucester, Monmouth, Derby, Stafford, Worcester, Leicester, South of Scotland.
Millstone grit	Sandstone for building, flags, roofing slates	West Yorkshire, Lancashire, Northumberland, Durham, Derby, Warwick, South Wales.
Mountain limestone	Lime, building stone, marble	Somerset, Devon, Gloucester, Salop, Monmouth, Leicester, Derby, Westmoreland, Cumberland, South of Scotland.
Old red sandstone and Devonian	Flags, lime, red and grey sandstone for building, slates ..	Various parts of Scotland, Salop, Gloucester, Monmouth, Hereford, Somerset, Devon, Cornwall, parts of South Wales.
Silurian	Sandstone and limestone for building, flags, slates, hydraulic lime	Wales, Hereford, Gloucester, Worcester, Monmouth, Stafford, Lake District, parts of Scotland.
Cambrian	Slates, sandstone, flags, limestone, lime	North Wales, Pembroke, Salop, Worcester, Leicester, Cumberland, parts of Scotland.
Igneous rocks	Granite, porphyry, gneiss....	Devon, Cornwall, Leicester, Westmoreland, Cumberland, large part of Scotland.
Metamorphic rocks	Serpentine, granite, syenite, marble, slate	Cornwall, Devon, Derby, Wales, Scotland.

ARCHITECTURAL ASSOCIATION.

At the fortnightly meeting of the Association, held on Friday, the President, Mr. H. L. Florence, in the chair, Messrs. W. S. Skinner and J. D. Webster were elected as members. Mr. PAGE, hon. sec., announced that the next "visit" would be made on Saturday afternoon, the 5th April, to three houses erected from Mr. E. W. Godwin's designs, for Messrs. Gillow, on the Chelsea Embankment, and that afterwards some of the studios of which Mr. Godwin had

recently told the members would be examined. Mr. HAYES, sen. hon. sec., announced that the sub-committee on the balloting question had agreed to a report, and that a special meeting of members would be held on Friday, the 18th April, to consider the desirability of altering the rules.

THE SCHOOL OF ST. LUKE, AT GHENT.

Mr. W. H. JAMES WEALE read the following paper descriptive of this school: My acquaintance with Belgium extends back to 1849. At that time there was no public interest whatever in architectural matters. Whenever any new building was erected, or any old one restored, the local papers uniformly lavished the most extravagant praise on the authors of the work. The only point that occasionally excited remarks of a different nature was the cost of these works. From 1849 until 1858 the only criticism of Belgian architecture that had appeared in the country was contained in two pamphlets by an English architect, then resident in Bruges, Mr. Thomas Harper King, with whose "Study Book of Medieval Architecture" many of you are doubtless acquainted; these related more especially to the new church of St. Mary Magdalene, at Bruges, the plans of which were considerably modified in consequence. In his translation, or rather adaptation of Pugin's contrasts, to which he made considerable additions, were some very just remarks on modern Belgian work, but at the time of publication these excited little attention. In 1858 I commenced the publication of a series of critical articles on the restoration of public buildings of the country. These drew some attention, and when, in 1860, the Royal Commission on Monuments was reorganised, I,

though a foreigner who had but recently settled in the country, was named a member of the Provincial Committee of West Flanders. Hoping to awaken public attention to the real nature of the so-called restorations, I seized the opportunity of the first general meeting of the Royal Commission at Brussels in 1861 to read a memoir on the restoration of the public monuments of the country. This memoir raised a regular storm, not only in the architectural world, but in several of the leading journals, and for several weeks I carried on a paper war with some half-a-dozen opponents. Of the seventy-two

members of the Commission, two only, like myself members of provincial committees, thoroughly espoused the line I had taken up, whilst about a dozen more gave me their more or less partial support. The Central Commission of Brussels, and the entire body of Government architects, became, of course, my bitter opponents. The two members who were with me were the Baron John Bethune, of Ghent, and Jules Helbig, of Liège. The former of these two gentlemen, years before, had one day, while copying the well-known picture of the "Elevation of the Cross," by Van Dyck, in the Church of Our Lady, at Courtray, been accosted by Welby Pugin. The young Bethune became his disciple in the church and town, listened, at first with some astonishment, to the English architect's remarks and criticisms, the points of which awoke a sympathetic echo in his mind, and between the two there sprang up an intimate friendship, which led to M. Bethune's taking up the idea of devoting his life to art. He came over to this country, studied glass-painting and metalwork with the Hardmans, and furniture and architecture with Pugin. He became the Pugin of Belgium, and has for many years not only designed and carried out a number of buildings, ecclesiastical and domestic, but has designed and directed the execution of a vast amount of articles of furniture in stone, wood, and metal, and himself designed and executed a large amount of stained glass. There is no living architect in Europe whose work resembles Pugin so much as his. My other adherent was M. Helbig, an artist, who, after studying painting in the Düsseldorf Academy, had gradually taken more and more to study the Mediæval paintings of the Low Countries, and to imitate with growing success the works of the best artists of the fourteenth century. For three people who met once a year to carry on a struggle with a powerful body like the Central Commission, and at the same time to contend with local opposition with any great chance of success, was out of the question. At last we determined to try and form a society composed exclusively of Mediævalists, and in September, 1863, we founded the Guild of St. Thomas and St. Luke for the study of Christian art and the propagation of its principles. This guild meets every year in some town, either in Belgium or in one of the neighbouring countries. The session lasts a week; the mornings are devoted to the examination of the monuments and works of art of the locality and neighbourhood, the evenings to reading papers and discussions, partly on the buildings and objects examined in the morning, and partly on some particular art question proposed at the previous meeting. It was by the guild that the Great Loan Exhibition of Ecclesiastical Art was got up and carried out at Meehlin in 1864, and which, owing to its taking place in connection with the Catholic Congress, did more than anything to propagate a taste for Mediæval art among both clergy and laity; the chronological arrangement of the specimens of church vessels and furniture there exhibited having been adopted with the especial view of showing the superiority of Mediæval art. The smaller loan exhibition of Bruges of 1867 was also got up by the guild, and this and the annual meetings in different towns brought recruits to our cause. Our views had gained ground, but those of our number who were architects or designers had the greatest difficulty in getting their ideas carried out. Designs put into other hands were modernised and classicised in their execution, and we felt that this would continue to be the case as long as art workmen received their education in the academies, all carried on according to the Government system. In 1864 one of our guild members, who, as a brother of the Society of St. Vincent of Paul, took an active part in the direction of a patronage for young workmen, found two boys who very much wished to learn drawing. The idea struck him that he might introduce this branch of instruction with good result; and having obtained the assent of the committee, he commenced a drawing class, for which he himself prepared the models. Other boys soon joined it, and the class increased little by little. Those members of the guild who resided in Ghent were naturally interested in the work, and promoted it, some by pecuniary aid, others by teaching. In 1869 it was determined to remove the class, which had greatly increased, from the patronage, and to constitute it a separate work, but still under the auspices of the Society of St. Vincent of Paul. The regular direction of

the class, henceforward known as the School of St. Luke, was confided to the Brothers of Christian Doctrine, and in 1870, when it was opened, in rooms of its own, 110 pupils were admitted. In 1871 the rooms were enlarged, a library and a collection both of casts and antiquities commenced, whilst, in addition to the class teaching, a course of lectures on symbolism was given. In 1872 the average number of pupils attending the classes held every evening had increased to 160, and the attendance at a special class, held on Sundays for those whose occupation hindered them from frequenting the evening school, to seventy. A series of lectures on construction were given this year by M. Arthur Verhaegen, who, after having passed his examination as civil engineer before the Government jury with the highest distinction, had adapted the profession of architect. In 1875 the buildings now occupied by the school were commenced. They are red brick, in the Flemish Domestic style of the fifteenth century, and were designed by pupils of the school. The interior is adorned with a simple polychromatic decoration. They were opened in 1876, in which year the evening attendance rose to 200, and the Sunday attendance to 100. The art collection received a very valuable addition in the shape of a number of drawings of articles of mediæval furniture bequeathed to the school by one of its earliest founders and friends, M. Florimond van den Poele, designer of the Convent of Vive, near Bruges, and of the manor-house of Scheldere, whose special talent for designing metalwork had led us to expect great things from him, when his useful career was closed by death at the age of forty-three. In 1877 the new buildings were enlarged. There are now in the evening school 350 boys, and in the Sunday class 120. In 1878 a school of St. Luke was commenced at Antwerp by M. Belpaire, engineer; M. Hendrickx, a pupil of Leys, and the author of the fine series of the "Stations of the Cross" in the cathedral and in the church of St. Joseph at Antwerp; M. Baeckelmans, architect of several remarkable churches; M. van Ryswyk, goldsmith and metalworker—all members of our guild. But this school is not under the care of the Brothers of Christian Doctrine. Another school was established at Tournay, under the management of Brothers trained at Ghent, aided by two members of our guild—M. H. Desclée and M. Cloquet, and a fourth at Lille. I hope that before the close of the present year a fifth will be in working order at Liège. I should have much liked to have been able to have put before you specimens of the pupils' work during each year of the course, which occupies seven years. This, however, was not possible, but I have here the set of models—fifty in number—which form the first or elementary series. The method adopted differs from that generally used in Belgium. The objects are in white outline on a black ground, easily seen at a distance, and intended to be reproduced on a slate or blackboard—a better system for beginners than that of drawing on white paper. The object is to form the eye of the pupil as quickly and as easily as possible by enabling him to see at once the defects in his work, so that he may himself try and improve his copy without waiting for the master to correct it. The classes in the school at Ghent are now complete; they include architectural drawing and construction, ornamental drawing and carving, figure drawing and painting, the complete course in each class extending over seven years. The regular daily direction is confided to the Brothers of Christian Doctrine, who are aided by members of the guild, the general supervisor and director being its president, M. John Bethune. I now wish to call attention to another institution carried on in a similar spirit, but the special aim of which is to form art workmen. About a mile from the town of Ghent, on the road to Courtray, in a small village named Maltebrugge, is an orphanage for boys, built and endowed by a wealthy cotton manufacturer of Ghent, M. Joseph de Hemptinne. It is a large quadrangular brick building, erected from the designs of M. John Bethune, with an elegant and spacious chapel, the chancel of which is richly decorated. The fittings and furniture throughout the entire establishment are in the mediæval Flemish style. Economy has been closely studied, and everything, with the one exception of the altar and chancel of the chapel, is extremely simple, but far more solid than the general run of fittings in institutions of this class, yet, owing to the careful attention given to every detail, the general effect is extremely

good, and even casual observers, after having gone through the buildings, come away impressed with the grandeur of the general effect. The orphanage contains over 300 boys, almost all sons of ordinary labourers. It is under the direction of Brothers of Christian Doctrine. The education is of course thoroughly religious, and not at all in accordance with popular current ideas of the present day. Those boys who show no aptitude for art, are, in addition to reading, writing, ciphering, and elementary geography, taught gardening, tailoring, shoemaking, or some other manual labour. But all those who show any disposition, and the proportion is large, are trained to become art-workmen. At the age of from twelve to fourteen very many of them are able to draw from Nature, and show an amount of feeling that is quite remarkable at so early an age. Instead of engaging skilled masters to teach the boys, which would have been expensive, and probably have led to no satisfactory results, a far better system was adopted. Two brothers, of the name of Blanchaert, one a stone carver, the other a carpenter and wood carver, were indemnified by M. de Hemptinne for removing their workshops from Honsden to the immediate proximity of the orphanage. Blanchaert, the stone carver, is a well-informed but quaintly simple peasant. Thanks to my late regretted friend, Sir John Sutton, Blanchaert in his younger days travelled over great part of Europe, studying the choicest specimens of Mediæval sculpture. He was one of the first to join our guild. In his workshop are now some fifty boys and young men engaged in carving statues, reredoses, pulpits, fonts, &c. In his brother's workshop are some fifty more, who make every description of furniture, from the simplest stool to the most elaborately-carved credence or cabinet. The plan pursued has turned out advantageously to all concerned. The masters, who formerly could not depend on the regular attendance of their men—on Mondays, for instance—and were affected by strikes, can count on regular attendance on every working day, whilst to the boys the advantage of working for a long number of years under the same direction is immense. In other ways, too, they derive special benefit. The wages they earn are paid to the institution, a certain sum being deducted for their keep, as also a percentage for buying off those who may have the misfortune to be drawn as conscripts for the army; the remainder accumulates, and is given to them on leaving the orphanage when they are grown up. There is also a workshop of decorative painting under the direction of M. Ad. Bressers. A foundry for works in brass and other metals has now been at work three years. Here lecterns, tabernacle doors, candlesticks, and other articles in latten, are turned out in all respects equal to old work. A bookbinders' shop has also been established, and a smiths' forge for works in wrought-iron is in contemplation. The whole colony leaves a decidedly favourable impression on the mind of the visitor, carrying him back in thought to the life and manners of the good old times of the Middle Ages. These schools have been started and carried on by men who believe that exclusivism, that is to say, the exclusive study of Christian models, is the only way to arrive at a regeneration of art. And so Classical and Renaissance, or as we prefer to call them, Pagan and Paganised Christian art, are rigidly excluded. Not only that, but in these schools the attention of the pupils is exclusively directed to Christian art of the north-western part of the Continent. All ancient art was the natural outcome of the people, and by an attentive study and analysis of its characteristics we can arrive at a clear idea of their religion, morals, and manners. Indian and Egyptian, Greek and Roman art are all alike in this respect. When Christianity permeated and changed society, there gradually grew up a new art which went on developing itself in a regular and logical manner, until its progress was arrested by the so-called Renaissance. These schools aim at reviving the traditions of Christian art, and for this reason exclude all that is antagonistic. For although in classical models there is doubtless much grandeur and a great deal of beauty, yet even in the best Greek art you will seek in vain for a single type of the two fundamental virtues of regenerated Christian society—humility and chastity. Where faith and morals are wanting there can be no hope of ever attaining the degree of perfection which our ancestors reached in the Middle Ages, far less of surpassing them, for art, according to the definition of the great

St. Thomas Aquinas, is nought else but the manifestation of beauty, and beauty is the splendour of the glory of God revealed in His creatures. Christian artists should be guided by this teaching, which explains the antagonism between the two schools: the Christian school which draws men towards the supernatural, towards their Creator; and the realistic school which drags them down towards creatures. The one seeks for beauty in Nature, and tries to reproduce its works with the greatest perfection; the other rises higher, and, looking to the source of eternal beauty, tries to derive some rays of glory from it. To become Christian artists we must commence by being thoroughly Christian. In the carrying out of this first principle lies the secret of the vigour, strength, and influence of the schools of St. Luke. Many eyes are now fixed, and many hopes founded on them, which I feel sure will not be disappointed. I began by saying that twenty years ago Belgium was, in art matters, behind England in every respect. I will end by saying that, in one respect at least, she is now ahead, in having schools founded on true principles.

Mr. G. H. BUCHAN proposed a vote of thanks to Mr. Weale for his novel and too brief paper. Anyone who had been in the Low Countries, and had criticised the character of the modern architecture, must have felt the need of such a society as the one he had organised. Bad as our restorations might be, England had never attained the mean atrocity of those carried out in Belgium, and specially those undertaken by the Government. At Bruges the town-hall had been recased and completely spoiled, and it was not the only instance of the kind in that town. In many cases in the churches Gothic work that was not even decayed was replaced by modern copies. He could bear testimony to the unwearied efforts of Mr. Weale for many years past to bring about a better state of public opinion, and believed that but for those exertions architectural affairs in Belgium would have been even worse than now.

Mr. ASTON WEBB, in seconding the motion, remarked that Mr. Weale's school was evidently special and exclusive, but seemed to have had good results in training up skilled workmen. Everything appeared to be kept from the members of the guild except Gothic architecture, and that being so, the education could hardly be deemed complete. Would Mr. Weale say that a Medieval carver would have been better for knowing nothing of Greek work? His own opinion was that a general course of styles was the first essential to success in architecture. The question arose how far was it in accord with the spirit of the present day to try to bring up a school of workmen to carry out carving as in Medieval times. For skill in modern work it would be better, he thought, to teach the workmen the study of the carving of the styles which succeeded Gothic, and which more nearly approximate to our own day.

Mr. WEALE said he did not intend his Christian artists to study Indian or Egyptian architecture, for it would be of no help to them, nor did he urge them to copy any style directly but to go to Nature. If the Medieval spirit and mode of study had been continued there would now have been but one style in this country. In restoration one must imitate the details of the work to be restored, but in building a modern church an endeavour must be made to show that it is new, and to give it fresh expression. He could say a good deal about Belgian art of the present day, but as he had only just left the country, he felt it would not be right to do so. He thought that in the town of Bruges he had obtained an alteration of the system of putting a false wooden cornice to every house, and also had set the example, since pretty generally followed, of sweeping the layers of whitewash and paint from the old brick houses.

The PRESIDENT, in putting to the meeting the vote of thanks, said that there were some defects in societies such as Mr. Weale had founded which he must advert to. One of those, that of the exclusive devotion to Medieval work, had already been referred to, and it would in time, he believed, prove a mistake. From the orphanage near Ghent a number of young workers would be sent forth who would find that in the greater number of new buildings going on their only style was not at all wanted. The novelty of the scheme would be lost in a very short time, and the style would degenerate into mere mannerism. There was also a want of a higher

class of teachers than the two village brothers, who, however zealous they might be, were very incompetent for the work of instruction.

THE INSTITUTE PRIZES, 1880.

THE conditions and subjects of the prize list for 1880 have just been published by the Royal Institute of British Architects. Candidates for the Pugin Travelling Studentship, who must be between 18 and 25 years of age, are required to send in their applications and testimonials together with a select number of their drawings and sketches on or before the 23rd January, 1880. All sets of drawings and essays sent in by competitors for the medals and prizes offered by the Institute, must be sent in on or before January 30th, 1879, and must be distinguished only by a motto, and accompanied only by a letter sealed with a blank seal, and having on the outside the same motto as that attached to the drawings or essays, inclosing the author's name and address.

The Soane Medallion and, subject to certain conditions, £50 will be awarded to the author of the best design for a Fine Art Museum for a large provincial town. The building is to be isolated on all sides, and its principal front is to face an open square. The ground floor is to be chiefly devoted to sculpture, coins, &c.—a portion only having a top light—with two or three rooms for curators. On the first floor are to be placed the picture galleries, lighted by skylights only, a fine art library, and a room for engravings. The ground-floor should be raised some three or four feet above the level of the street, and areas should be formed around part of the building, to afford ample light to the basement, in which the surplus collections are to be stored, and works of art received and unpacked. Provision is to be made in the basement for refreshment rooms, as well as for retiring rooms for ladies and gentlemen respectively; and a residential set of rooms for the porter is to be provided in the basement. The site to be occupied by the building and its areas should not exceed 15,000 feet superficial. The drawings required will be, ground and first floor plans, principal elevation, section through the galleries, section through the staircase, each drawn to a scale of 8ft. to one inch; perspective view, and a portion of the principal elevation drawn to a scale of 2ft. to one inch. The further award of £50 will be given to the successful competitor, upon arrangements being made for his going abroad for a period of six months, in order to pursue his architectural studies, within two years after receiving the medallion.

The Tite Prize of £30 will be awarded to the author of the best design in the Italian style for a mausoleum. The plan is to be that of a Greek cross with a dome in the centre, the interior diameter of which is to be 35ft. The drawings required are a plan, an elevation, and a section, each drawn to a scale of 4ft. to the inch, and one sheet of details on a scale of 2ft. to the inch. Careful adaptation to English climate and modern ages will, the Institute Council intimate, be considered in the award. This and the Soane competition are open to all members of the profession under 30 years of age.

The Grissell Gold Medal is to be awarded for drawings illustrating the design and construction of the groining of a church, width of nave 30ft. A plan, longitudinal and transverse sections, each drawn to a scale of 2ft. to the inch, are stipulated for, and perspective diagrams, showing the jointing, may be added; but the joints of the masonry must also be carefully shown in the geometrical drawings. Colour may be used, but only for the purpose of showing the construction and distinguishing different materials.

The Silver Medal of the Institute, with five guineas, will be awarded for the best illustrations drawn from actual measurement (with dimensions figured both on the general and detailed drawings) of any important building—Classical or Medieval—in the United Kingdom or abroad, hitherto unpublished in that manner. A town or country house, erected between the years 1600 and 1750, is suggested as a subject worthy of illustration, but any of the following buildings may, however, be taken if more convenient to the competitor:—Kelso or Dunblane Abbey, Cashel Cathedral, or any monastic building in Ireland, St. David's Cathedral, Entrance Gateway, Middle Temple-lane, Steeple of St. Magnus the Martyr, London-bridge, Steeple of

Newark, Notts, Long Melford Church, Suffolk, or the north-east transept of Beverly Minster. The drawings must not exceed six in number. They must consist of at least one plan drawn to the scale of 8ft. to the inch, or, in the case of very large buildings, of 6ft. to the inch; also of one elevation and one section drawn to the scale of 8ft. to the inch, with details drawn to a scale of 2ft. to the inch, the profiles of mouldings being given 1-11th full size. The elevation and details are to be in outline only; the plans and sections are to have only the sectional parts hatched or shaded. Perspective drawings may also be sent, and they may be etched in Indian ink or tinted in sepia. The jointing of masonry must be carefully indicated, showing mode of construction and materials used. Competitors must send, with their finished drawings, the rough sketches plotted on the spot. This competition is open to all members of the profession without limitation.

The Essay Competition, which has been a failure during the last few years, is again opened, but in addition to the Institute Silver Medal, the sum of ten guineas is offered for the best essay on the subject of "The Architecture of London in the Sixteenth Century," the same subject as that suggested last year, except that the period to be treated ranged from the sixteenth to the eighteenth centuries. Each essay must be accompanied by suitable illustrations, and the competition is open to all competitors without restriction as to age.

PICTURES FOR THE ACADEMY.

MESSRS. PILGERAM and LEFEVRES have had on view at their galleries in King-street, St. James's-square, a few paintings intended for the forthcoming Royal Academy Exhibition that possess more than ordinary interest. Mr. John Smart, R.S.A., is represented by two landscapes of remarkable power. One entitled "Far from the Busy World" sustains Mr. Smart's well-achieved skill as a painter of broad and vigorous effects. The scene represents Scotch moor with cattle and water in the foreground. The ruggedness of the moor, and the heavy cloud are happily suited to the artist's broad and energetic handling. His "Drummond Hill, Perthshire," is one of those impressive views of mountain that meet us in the grand scenery of the Scottish Highlands. The light thrown across the mountain is skilfully managed and the effect of height and distance enhanced by the introduction of a bird on the wing, which catches the light. In the foreground the painting lacks solidity and tone. Miss Henrietta Browne's "Le Ducat" is a portrait study. An old man, apparently a Jew and curious, dressed in a long coat, with cap, is busily engaged turning over his collection of coins and plate. In one hand he holds a coin, which he is examining through a glass. The face, hands, and general drawing are excellent, and the artist has succeeded in producing a well modelled, richly toned, and delicately painted subject evincing a thorough mastery of the figure. Perhaps, the most striking painting on view is Mr. W. E. Lockhart's "Gil Blas, and the Archbishop of Granada," representing the archbishop in his scarlet robes, standing on a landing, with sternness on his face, rebuking the hero of Le Sage, who, cap in hand, dressed in the yellow Court dress, descends the steps. The wealth of tone, light and shade, the expressive cast of features in the old and young man, and the rich costumes, add a dramatic force and charm to the incident told by Mr. Lockhart with so much reality. "Frère and Sœur," is the title of a small cabinet picture, by Mr. Edward Frère. Its interest is centred in a humble interior, in which a little boy is engaged holding a skein of wool for his sister. The tale is simply told, and homely, and Mr. Frère's softness of touch, perhaps, adds to its charm. We cannot admire the drawing of Sir H. Thompson's "Grand Canal, Venice," but as an amateur's work, we at once overlook any technical qualities, and can appreciate the art feeling displayed. L. Alma Tadema, A.R.A., is to exhibit, we understand, several pictures which Messrs. Pilgeram and Lefèvre will have on view during the next few days. We believe one is entitled "A Hearty Welcome," another, "In the Time of Constan-

The first stone of the new spire to St. Peter's Church, Bournemouth, was laid on Tuesday weeks

KINGSTOWN TOWN HALL.—THE WINDSOR AND ETON ALBERT INSTITUTE.—EOANE MEDALLION DESIGN FOR A HOUSE FOR THE LEARNED SOCIETIES.—DESIGN FOR LACE CURTAIN.

OUR LITHOGRAPHIC ILLUSTRATIONS.

KINGSTOWN TOWN HALL.

The foundation-stone of this new building was laid during November last year, the design having been selected in competition in the autumn of 1874. To-day we publish a view of the building from the Crofton-road. Mr. John L. Robinson, of Great Brunswick-street, Dublin, is the architect; and Messrs. Meade and Son are the builders. The contract was taken at £12,340. The building will contain a court, with witnesses', judges', barristers', and jury rooms, and clerk of the peace offices. The township offices comprise board-room, town-clerk's offices, surveyors', rate-collectors', and sanitary offices. The large assembly-room is 75ft. by 41ft. 6in., with retiring and cloak rooms. The building is faced with chiselled Dalkey granite, and has Bath stone and red Runcorn dressings. The work is to be completed within two years.

THE WINDSOR AND ETON ALBERT INSTITUTE.

The foundation-stone of the above building was laid on Friday last by Prince Christian. The plans—which were selected in open competition—are by Messrs. H. F. Bacon and E. Ingress Bell. The building has a frontage of about 70ft., and consists of three stories, comprising a great hall for public entertainments (with artistes' rooms in connection therewith), lectures, &c.; a library, reading-room, and ladies' reading-room; a museum, art and science class-rooms, committee-room, care-taker's quarters; stores and warming-chamber in the basement, and the customary accessories. The main entrance is in the centre of the façade, the reading-room being on the right hand, and the library and ladies' reading-room on the left; immediately in front of the visitor the great hall is entered by two ample doorways, between which it is proposed to place a bust of Her Majesty the Queen. The great hall is 66ft. long, 33ft. wide, and 25ft. high, and will accommodate 500 seats, exclusive of the gallery over the entrances. The principal front is designed in the style of the 15th century. It is being executed in red brick, with dressings of a warmly-tinted freestone, and will be embellished with carving, sparingly introduced. In the centre of the *premier étage*, and on a pedestal in a carved and canopied niche, a statue of the Prince Consort is intended to occupy the place of honour. Mr. Woodbridge, of Maidenhead, is the contractor for the works.

EOANE MEDALLION PRIZE DESIGN, 1879, FOR A BUILDING TO ACCOMMODATE FOUR LEARNED SOCIETIES.

The accommodation provided is in accordance with the instructions, and is similar for each of the four societies, with a lecture-hall in common. Examining one of the sets: The library is fitted for 5,000 volumes, and has a gallery round, supported on coupled swept trusses. It is principally lighted by the windows in the bays, which are above the wall space, which is valuable for book-shelves; the ceiling is to be formed by semicircular arches, abutting on the sides of bays, which carry the flanks of bays above the roof. The bays are also arched across, and the ceiling of panelled plaster follows the lines of these arches. A librarian's room is attached. The reading and writing-rooms adjoin, and are separated by a screen. They each have bays, and are planned to obtain as much light as possible, and to be easy of access. The principal lavatories and cloak-room are in mezzanine, over the subordinate rooms of the ground-floor. The entrance is from the courtyard by the doorway, a detail of which is given, and has w.c. and cloak-room attached. The staircase rises immediately from the entrance. On the ground-floor are the council and committee-rooms, secretary's and clerks' offices, with separate entrance, cloaks, and w.c. The lecture theatre is seated for an audience of 300, and is provided with ample entrances both from the courtyard and externally. A detail of one bay of the elevation is furnished. The ceiling is to be waggon-beaded over each limb of the cross, and flat, with deep cove over the crossing. Caretakers are provided for in the basement. There is also an attic story with dormers, which break the roof. It was felt that the courtyard plan would lend itself most readily to equality in the arrangement of the four sets, and to efficient lighting and privacy. The style chosen was Renaissance, the chief intention of which was to do without an order, and to obtain some originality without the eccentricities of the later developments. The drawings required were eight, of which the perspective and sheet of details are illustrated.—W. R. L.

DESIGN FOR A LACE CURTAIN.

The illustration given this week is from a design by Sidney Smith, a student of the Nottingham School of Art. It was exhibited among the national competition works, at South Kensington, last year, and gained a silver medal. The fabric is intended to be made on a lace machine. The style is technically known as "Guipure d'Art," and is a reproduction, as far as can be done by machinery, of the 16th century hand-made lace, known as "Puato in Aria."

THE AMALGAMATED SOCIETY OF CARPENTERS AND JOINERS.

WE have received the Nineteenth Annual Report of the Amalgamated Society of Carpenters and Builders. It congratulates the members that although the past year has been one of commercial depression and disaster, resulting in severe suffering to trade organisations, and heavy taxing on the resources of the society, yet it is still in a sound financial condition, and the diminution of accumulated capital has been comparatively trifling. During the year thirteen new branches have been opened and six were closed. The total number of members at the close of the year was 16,574, being 255 less than at the end of the previous year. Notwithstanding that the largest and most costly strike ever known of the trade took place in the first five months of the year, yet the income was only diminished by £632 14s. 1d. from those of the previous year, the total receipts being £41,598 14s. 3d. The expenditure amounted to £44,476 14s. 7d. showing a loss on the year of £2,878 0s. 4d. A valuation of the buildings and other property of the Society shows that the assets are worth £76,166 6s. 5½d., or £4 11s. 11d. per member. In unemployed benefit £10,504, or 12s. 8d. per member was paid, the largest sum per member since 1871, and for trade privileges including strike pay, arbitration, and legal expenses, £12,292 or 11s. 10d. per member. "Attempts to reduce wages are now being made," the report notes, "in many of our northern and midland towns, and while in most of our larger towns and cities employers are honourably adhering to their agreements, and giving due notice of their intention to reduce wages, in other localities they are taking every possible advantage of

the depression of trade, and are giving only a few days' notice of reductions to workmen from whom they have received as many months' notice whenever an advance of wages has been desired. Such conduct is unwise in the extreme. The tide will turn some day, and their conduct will not be forgotten. We have been endeavouring to impress on members the desirability of giving to their employers ample notice of their intention to claim advances in wages, to enable them to finish existing contracts without loss and to provide in new ones for the increased cost of labour. In some towns all efforts in this direction are being neutralised by the short-sighted policy of the employers, who will eventually mourn over the consequences of their own folly." Reference is also made to the Government Bill dealing with the liability of employers for injuries to workmen, which it is suggested is not intended to be passed. The secretary, Mr. Prior, says he has no hope of obtaining a satisfactory measure from the present House of Commons, and urges the members to make their power on this question felt at the next general election.

COMPETITIONS.

CITY OF LONDON SCHOOL.—Fifty-three architects have sent in designs for the proposed new building for the City of London School.

HARVEY TERCENTENARY MEMORIAL.—The models for the statue of Harvey which it is proposed to place at Folkestone will remain on view in the picture-gallery of the South Kensington Museum until the evening of to-morrow. The models are three in number, distinguished by the letters A, B, and C, and were reviewed by us on p. 244. The scale is three inches to the foot. It is intended that the statue shall be of bronze and the pedestal of granite. At a meeting of the sub-committee held on Monday at the Royal College of Physicians, Sir George Burrows, M.D., in the chair, it was decided that the commission for the statue should be intrusted to Mr. A. Bruce Joy, who is the designer of the model marked B. About £1,800 has already been subscribed, and £200 more will be needed to defray the cost of the memorial.

IPSWICH.—The town council of Ipswich recently received seven plans for the adaptation of the Public Hall, so as to serve as a corn exchange without unfitting it for the purposes to which such a building is usually devoted. These were sent in under the several mottoes of "Tria Juncta in Uno," "Bona Fides," "Exeelsior," "Economy," "Utility and Economy," "Grosvenor," and "Postulata." A special meeting of the town council was held on Wednesday last, when in accordance with the report of a committee, the premium of fifty guineas was unanimously voted to the plan of "Tria Juncta in Uno," and upon opening the sealed envelope, the author was found to be Mr. Horace Cheston, 1, Great Winchester-street Buildings, London, E.C. The estimated cost of the scheme is £3,400, but it should be added that the town council have not yet decided whether to alter the public hall as suggested, or to build an entirely new corn exchange and public offices at the rear of the town hall.

NEWTON ABBOTT.—At a meeting of the shareholders of the Newton Abbott Coffee-Tavern Company it was decided that the tavern should be erected in Market-street, from the designs of Mr. Jones, architect, of London, which had been selected by the Directors. The opposition, which was weak and frivolous, sprang from motives of jealousy.

On Tuesday week, at the Anthropological Institute, Sir Charles Nicholson, Bart., read a paper upon "Rock Carvings." These are to be found in various parts of the harbour of Port Jackson, New South Wales, representing the human figure, kangaroos, whales, &c. One, a whale, was fully thirty feet in length. The remarkable circumstance about these carvings on the carboniferous sandstone is their evident antiquity. Earth has gathered upon the sculptured surface of sufficient depth to sustain forest trees.

An oil painting of the late Alderman W. G. Ward has been hung in the Dawson gallery of the Castle Museum, Nottingham, in the establishment of which Mr. Ward devoted all his powers. The portrait is the work of Mr. S. Redgrave. Among other recent additions to this museum are three cases of Indian embroidered saddlery, armour and weapons, purchased at the late Paris Exhibition.

THE RESTORATION OF TEWKESBURY ABBEY.

IN view of the reopening of Tewkesbury Abbey in September next, a public meeting was held in the library of Lambeth Palace on Friday afternoon. A number of drawings and views, including a series of water-colour sketches by the late Rev. J. L. Petit, of Lichfield, were hung in the room. The Right Hon. Sir Michael Hicks-Beach, M.P., occupied the chair, and in opening the proceedings urged that the abbey had especial claims on the country at large for reparation and maintenance. As a rule when parish churches needed restoration there was no special difficulty in raising the means in the neighbourhood, for they were not generally much larger than suited local requirements, nor required greater funds than could be raised in the immediate district. Our cathedrals were known far and wide as great national monuments, but were felt to be in a peculiar sense the property of the diocese or county in which they were situated, and in all cases that responsibility had been cheerfully accepted and borne. But the case of Tewkesbury Abbey was very dissimilar to either of these; it was of a size far beyond the needs of the townspeople, while it had no cathedral body, nor funds, nor the widespread fame and interest which attached to the centre of a diocese. Special means had therefore to be taken to bring the absolute necessity for its restoration before the nation at large, and to attract general sympathy and interest. As to "restoration" he was very conservative. In the first place he would say, Keep a building in repair, even remove any of the discrepancies which have been added to it, but do not add any of your own fancies; and treat all you find there soberly and reverently. Too often these rules were broken in so-called restorations, but no fault of that kind could be found at Tewkesbury. He believed the abbey was safe in the hands to which it had been intrusted, and that the restoration would be carried through in a conscientious spirit.

The Rev. H. ROBESON, vicar of Tewkesbury, read the report of the Restoration Committee. It stated that very considerable progress has been made towards the restoration of this, the largest abbey church in England, since the meeting held in March, 1877, when a National Committee was formed to co-operate with the Restoration Committee at Tewkesbury. The works done since that meeting include the removal of all plastering and whitewashing from the walls, pillars, piers, and vaulting of the nave, a task nearly finished, and which has in places revealed work of a highly artistic character. The ornamentation of the nave vaulting is now being proceeded with under the personal care of Mr. T. Gambier Parry, to whom this part of the work has, with the approval of the architect, Mr. J. Oldrid Scott, been entirely confided, while a stone pavement laid on the ancient level discloses the full proportions of the massive Norman pillars, and gives greater dignity and effect to the whole interior. The floor of the transepts, chapels, &c., has been concreted and repaired, and the two ancient chapels adjoining the north transept (until lately erroneously known as the Chapter House), and which have for long been in a ruinous condition and cut off from the church, are being also re-roofed and otherwise restored. The Rev. C. W. Grove, of Tewkesbury, has presented an oak eagle; while Mrs. B. T. Moore, also of Tewkesbury, has undertaken the cost of a new font. A striking feature has been added to the eastern end of the church by the generosity of Earl Beauchamp, who has at his own sole cost restored to its ancient position the old altar-slab, mentioned by Dingley in his "History from Marble" as the largest in the kingdom. This slab, divided in half, has for generations served for seats on either side of the north porch. It is now mounted upon a massive oak frame, and is regularly used at the celebration of the Holy Communion. Earl Beauchamp also included in his gift two handsome altar-coverings. The interesting Clarence Vault, containing the skulls of the famous Duke and Duchess whose name it bears, has also been repaired. Other works have been carried out, or are in a fair way towards completion, including necessary repairs to the roof of the fabric, a thorough system of drainage surrounding the building, the restoration of the north-west porch and gates, which form the

principal entrance, and the improvement of the approaches generally. Much costly work still, however, remains to be done in the reparation of nearly all the interior fittings of the church, as well as much-needed and considerable external repairs. One important item has engaged most careful attention, viz., the enlargement and rearrangement of the organ, for which it is proposed to erect an organ-loft across the north transept-arch and above the north choir stalls. The execution of this work has been intrusted to Mr. Henry Willis, of London, whose estimate for the alterations and improvement (retaining as much of the ancient organ and its case as is possible) amounting to £700, has been accepted. The amount of payments already made, and for existing contracts, reaches the sum of £7,911, to which must be added the estimated cost of restoring the ancient stalls, the enlargement and fixing of the organ, the decoration of the nave vaulting, the levelling of the churchyard and other external repairs, in all £1,225, making a total of £9,136. The subscriptions hitherto received amount to £8,694, to which may be added a conditional promise of £500 by the Vicar and his sister, making a total of £9,194, thus leaving a balance of only about £58 at the disposal of the committee. The committee have carefully refrained from contracting any debts, or from entering into any contracts the expenses of which they were not prepared to meet, and therefore appealed with more confidence for further aid from the public.

Earl BEAUCHAMP moved "That this meeting, having heard the report of the Restoration Committee detailing the works which have been carried out during the past two years, desires to express its entire satisfaction with the progress which has been made, and cordially invites the co-operation and aid of all who are interested in a work of such great national importance as the careful and judicious restoration of the largest existing abbey church in this country." The work had, he said, been frugally and judiciously carried out; no other restoration of like extent had been carried out for so little money.

Lord SUDELEY, high steward of Tewkesbury, seconded the resolution, which was carried unanimously.

Mr. REGINALD YORKE, M.P., proposed that the names of the following gentlemen be added to the National Restoration Committee:—Rev. Canon Barry, Messrs. Thomas Blashill, A. W. Blomfield, H. C. Coote, E. B. Ferry, J. F. France, S. W. Kershaw, Bowes A. Paice, R. B. Prosser, J. P. Seddon, and Wm. White; and that a London sub-committee for the purpose of collecting the funds required for the completion of the work be also formed. Mr. Yorke compared the state of the abbey in 1865, before the restoration was commenced, and at the present time, and said there were grounds for congratulation in the changes effected in the appearance of the abbey. The resolution was seconded by Mr. BLUNT, and agreed to.

Mr. JOHN OLDRID SCOTT read a report on the abbey and the works that are being carried on under his supervision and from his designs, opening by expressing his acknowledgments to the Restoration Committee for the confidence they had reposed in him. It was his earnest intention to pursue the course laid down by his father, and to act in the same spirit of true Conservatism by which he was always inspired, and which in this case is, Mr. Scott significantly added, happily shared in to the fullest extent by the committee themselves. The Abbey is built mainly in two styles—Norman of a very plain kind, and a beautiful variety of Middle Decorated. The Norman abbey was founded early in the 12th century, and consisted of a long nave with aisles, transepts united by a grand central tower, and a choir, also with aisles, terminating in an apse, surrounded by an ambulatory, from which no doubt projected chapels, as they did also from the eastern walls of the transepts. The two chief characteristics (both of which still remain) must have been the grand central tower, richly arcaded, and surmounted as it then was by a wooden spire, and that which yet gives it especial individuality, the remarkable western front, the central part of which is occupied by one vast arch, extending from the ground to the roof, recessed in seven bold orders. This was no doubt originally filled in with a number of Norman windows, but of these we have now no record. The present appearance of this front is much injured by the loss of the gable which rose

above it till the 17th century, when all the high roofs were unhappily swept away, to the great loss of the building. Internally the abbey, which was in those early days exceedingly plain, had a curious feature (which it possessed in common with Gloucester and Pershore) of remarkably tall columns and arches in the nave, contrasting with very low ones in the choir. The building continued as its Norman founders left it for some 200 years, when early in the 14th century an astonishing change took place. In the nave this was confined to the insertion of tracery windows throughout, and the substitution of stone groining for the flat or coved wooden ceiling, the same being done in the transepts. In the choir, however, a far greater alteration was effected. The ambulatory was first taken down and rebuilt farther out, and from it were projected the most beautiful series of chapels to be found in this country, except indeed at Westminster. All of these now remain with the exception of the Lady Chapel, which was on a far larger scale than the others, and which from the precious fragment of its west end still existing, must have been a building of extreme beauty. The date of these works must have been early in the century. Immediately afterwards the whole of the choir was pulled down, the Norman columns only being left, and rebuilt in the richest variety of the prevailing style. A lofty clerestory was erected, consisting of some noble windows of the finest design, which are still filled with their original stained glass. The groining, too, was of the most elaborate description, and the whole of this part of the building within and without is of almost unequalled elegance and picturesque beauty. The new walls were of the same height as the old ones, but the roof was arranged slightly lower than before, so as to allow of the addition of the beautiful parapet—now, unhappily, almost ready to crumble away. At this time and subsequently the eastern part of the building was further enriched by a magnificent series of Chantry chapels and monuments. These alone are sufficient to place Tewkesbury in the very first rank among our great churches in point of historic interest. Two more peculiarities relating to the interior which distinguish Tewkesbury Abbey as it has come down to us remain to be noticed. The marked contrast between the noble simplicity of the nave and the exceeding richness of the eastern portion is the first. This is very striking, and the skill with which the two are brought into harmony by groining of a somewhat similar character being continued throughout the whole length is worthy of especial observation. The other feature to which I would allude is the unusual proportions of the interior. No other building of this nature gives such a remarkable impression of breadth and expanse. This is no doubt due to the height being in such a small ratio to the width; but it is the breadth of the building which strikes the observer, and not its want of elevation. Reference should be made to the exquisite thirteenth century work adjoining the north transept. There was at first a Norman apsidal chapel here, which was rebuilt in the thirteenth, and again in the fourteenth century; but just beyond this, in a very unusual position, viz., at the extreme north-east angle of the transept, there still remains a most beautiful little building, dating from the commencement of the Early English period, though with subsequent alterations. This can be shown to have formed the chancel of the small church, the nave of which ran across the north front of the transept. It has been conjectured with much probability that it was erected to form a Lady Chapel for the use of the parishioners. The design of its nave can still be traced with some accuracy, and it must have been a feature almost unique and of the greatest beauty. Should its restoration ever become possible, it would be indeed a charming addition to the Abbey, and one, I cannot doubt, of great utility. But I must proceed to describe the works we have in hand and those which are proposed. The cleansing from modern plaster and whitewash and the repair of defective stonework, spoken of in the Committee's report, refers only to the interior of the abbey. What is of special interest here is the treatment of the vaulted ceiling. The bosses of the groining when first uncovered showed signs, although not very distinctly, of their ancient decoration, and it was at the time determined to restore them. The result, however, was unsuccessful, and the treatment was stopped

after two bays had been so dealt with. The carving of the bosses throughout the roof is of the highest value and interest, the subjects of the central range consisting of scenes from the *Life of Our Lord*, while the two side rows are occupied with angels bearing censers or playing upon musical instruments. Nothing can exceed the artistic feeling displayed in these sculptured bosses; but, from their being in most cases hardly more than sketches, it quickly appeared that any treatment of them in full colour tended only to obscure their design, and to emphasise their incompleteness. So much was this felt that for a considerable time it was the opinion of M. Gambier Parry and of myself that it would be best to attempt no decoration whatever. The greater part of the ceiling was, therefore, left plain, but the effect from below was by no means satisfactory, and at length Mr. Parry proposed a mode of treatment which he has now carried out in a portion of the groining. I desire to express my great admiration of the skill and judgment shown in this work. The committee unanimously concur in this opinion, and it has been decided that the treatment shall be continued throughout the whole of the nave. The floors of the transepts, ambulatories, and chapels have been made good in all respects. The Decorated chapel east of the north transept is in course of careful reparation, the east of which is being borne by the Provincial Grand Lodge of the Freemasons of Gloucestershire. Some pressing repairs are also being carried out in the Early English chapel to the north of this, already alluded to, but not to the extent of anything like complete restoration. Important works have been carried out in the choir. Of the ancient stalls, a sufficient number remain to complete the back row on both sides of the new arrangement. In addition to these, considerable portions of the 14th century stall backs, or screens, which rose above them, are in existence. It has been decided to restore the stalls to their original position beneath the tower, and to erect above them these ancient screens. Unfortunately, only sufficient length of the latter remains for the north side, and this alone has been ordered by the committee, the funds not being sufficient for the new screen required on the south side. Eventually, a second row of seats must be added for the choir boys as well as book-rests, but at present this part of the arrangement must be temporary, the total expenditure needed for the complete re-arrangement of the choir amounting to between £700 and £800, of which the committee are only able to undertake a very small portion at present. Various proposals have been made as to the choir screen, but the only designs prepared have been for a low inclosure of ornamental character. A wooden model of the most recent design has been made, so that its effect may be well considered. It is my own opinion that this church should eventually possess a high choir-screen, of very open design, but sufficiently elaborate to accord with the ancient fittings. The font at present consists of a base and shaft of Decorated date, carrying a bowl of very mean appearance, probably belonging to the 18th century. A new bowl has been designed, agreeing in style with the ancient part. It will be Purbeck or some similar marble. The font when completed is to be surmounted by a lofty wooden cover of tabernacle work, the design for which has been founded on an ancient fragment of 14th century woodwork remaining in the abbey. Great pains have been taken over the design, which is now being carried out by Mr. Collins, the contractor for the restoration works. A pulpit is much needed, and it is essential that it should be worthy of this grand building. As to the chantry chapels, it appears to me that it would be the wisest course to leave them without anything like complete restoration. Some slight repairs are actually required, and should be undertaken, but nothing beyond this would be desirable. The case of the sedilia is different, these being a necessary part of the furniture of the church. Happily, the greater portion remains. The design is noble and characteristic, and I think it would be well to complete them. The restoration of the clerestory windows really forms a part of the external reparation of the stonework. In proportion to the size of the building, not much work of this nature is necessary, and it would not, I think, be wise to do more than is absolutely wanted. The roof of the south aisle of the nave is, however, in a very bad state, and requires re-tiling, as well as other repairs. As to a reredos, no resolution has been

come to by the committee, although I have prepared a sketch design with a view to elicit opinions on the subject. Considering how the choir is flanked by a noble series of chapels and towering monuments, I feel that it can never look complete until its eastern extremity is occupied by a reredos as dignified as any of them. It would be necessary to give any reredos erected here a considerable amount of local character, introducing among its sculptures figures of those eminent personages with whom the history of the abbey is so intimately connected. The north porch to the nave is now being carefully repaired, and is nearly finished; the very sumptuous iron gates which have stood in connection with it for the last 150 years will be retained, though their level will be lowered. The floor of the nave has now been entirely lowered to its ancient level with a very good effect; the step which we discovered to have marked the position of the ancient roof-screen which separated the conventual from the parochial church, being restored. Finally, a few words require to be said about the organ. The position decided for it is beneath the north arch of the central tower, above the screen forming the back of the stalls. The fine old case will be strictly preserved, a very small addition being made to its lower part to adapt it to its new position. It is of great value and beauty, and from its details must be one of the earliest in the country. Such then is an account of the works either in hand or contemplated. All are of importance and indeed of pressing necessity, but the means at the disposal of the committee compel them at present to postpone a considerable proportion of them. It is greatly to be hoped that the publicity now being given to this great work may lead to substantial help being received.

Mr. GAMBIE PARRY, in proposing a vote of thanks to Mr. Scott for his paper, explained the work he had himself been engaged upon in the nave roof decorations. This vault was, he said, a most interesting specimen of English carving; the roofs of Gloucester, Norwich, and Tewkesbury were the three finest in this country. But this roof was but a series of grand skeletons; it seemed as if the carver had chopped away just as the spirit moved him, leaving it to the colourist to complete the ideas he had suggested. The figures in the bosses were remarkable for their size; the angels carrying all sorts of musical instruments were about two-thirds the size of a woman, and the central bosses, in which were represented the *Life of Our Saviour* from the Nativity to the Majesty, were even larger. In the Crucifixion, the figure is about 3ft. in height, but, strangely enough, the Cross was left for the decorator to fill in. The task he had undertaken of renewing the colour which formerly existed on these carvings was one of considerable difficulty, and concerning it various opinions would be held. That, however, he had experienced before. During the time that he was at work in Ely Cathedral he met a clergyman who, on hearing that he was acquainted with that Cathedral, exclaimed "Oh, there's a horrid fellow daubing over that beautiful building; I wish he might be hung to a lamp-post and cut into a thousand pieces!" Mr. Parry said he was a little amazed at the outburst, but he explained that he himself was the "horrid fellow," and they parted as good friends. At Tewkesbury he had found the greatest difficulty in the work on account of the extreme and necessary simplicity demanded by it. It would be very easy to colour the roof; but to apply the right lines and touches of colour at the best places for effect would demand the exercise of consummate art. There were a few records in the stones of what the ancient treatment resembled, and he believed it was coarse. The difficulty was that any system of high colour—vermilion, gold, and blue—applied to a few points had a tendency to look blotchy, whereas, to be satisfactory, the effect should be one of complete harmony, of perfect peace. The aim of the decorator should be, consecutiveness, proportion, rhythm. In this roof there was a great deal left so vague that one must follow out his own ideas in completion; the nimbuses, &c., had been supplied by the artist, and this rule he had endeavoured to follow, venturing to add a cross in gilding beneath the figure of the Crucified One. Among the instruments borne by the angels were the rebec, shawm (a sort of bass clarionette), psaltery, and bagpipes. There were also a pair of very curious figures, which were declared by one set of commentators to be Fitzhamon, founder of the

abbey, and his wife, but which others thought to be only Adam and Eve.

Mr. AGG-GARDNER, M.P., seconded the vote of thanks, which was briefly acknowledged by Mr. Scott; and the proceedings closed with the usual compliments to the chairman and the Archbishop of Canterbury for granting the use of the library. The visitors afterwards availed themselves of the Archbishop's permission to inspect the palace-chapel and dining-hall, &c.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

ARCHITECTURAL FOLIAGE.

WE give this week, in continuation from p. 339, the second part of Mr. J. K. Colling's paper on "Architectural Foliage," read at the meeting of the Institute on the 24th ult., with the subsequent discussion:—

In designing foliage we have chiefly two things to study. Form, and light and shade. In form the first thing we have to decide upon is the leading or setting-out lines of the composition. And whether these consist of the scroll form, the branched, the radiating, or any other lines, they must intersect and divide the space to be filled, in the same manner that the ribs and veins do the surface of a reticulated leaf. No portion must be left unprovided for, and they must harmonise with the bounding or other architectural lines of the work itself. These should be laid out upon a geometrical and somewhat regular and symmetrical plan, and we can but partially obtain any assistance for this purpose from nature. But there are some general ideas that we can gather, such as the scroll lines we see in tendrils and climbing plants, the various modes of branching, the reticulation of leaves, and the radiation of flowers. Architectural foliage should represent natural growth, and not be formed with flowers, fruit, and leaves picked and separated from life. Crooked form, such as we find in nature, must be altered to the tangential or angular, or a combination of both. We should remember also that upright lines represent life, hanging or dropping lines decay and death. Having decided upon the leading lines of our stems, the next process is to clothe them with leaves, flowers, and fruit. Here we may bring to our aid that variety and beauty of form with which nature supplies us so bountifully. As a general rule all well marked and deeply cut lobed leaves are most applicable to carving, such as the irregular lobed leaves of the acanthus, thistle, hawthorn, oak, and the chrysanthemum; radiating leaves, as the horse-chestnut, cinque-foil, vine, and maple; or those which have separate leaflets as the trefoil, rose, ash, and acacia. Perfectly plain leaves, such as the lilac, box, laurel, and olive, are also valuable where simplicity and breadth of form are required; or the complicated can be reduced to their first simple form. Nature proceeds in this manner herself—in one leaf, the *Maranta*, has herself painted the forms of the plain leaf. Leaves mostly assume, more or less, the forms of the geometrical figures. The *Laurestinus* gives that of the vesica. The *Cinearia maritima* is of the same general form, but is cut into deeply rounded lobes, of the same type as the oak. All compound leaves still retain the general forms of the more simple ones, as shown by the rose-leaf. The dock has a leaf of an oval form, found again in the deeply crenate-lobed leaf of the greater celandine. The heart-form is seen in the black bryony and violet, and again in the leaflets of the clover. The main ribs of the leaf of the black bryony assume very beautiful flowing forms, having a strong resemblance to the lines of the Greek-honeysuckle. In the violet, the ribs are quite different, and branch from the midrib, while in the bryony they flow gracefully from the base of the leaf where it joins the foot-stalk. The ground ivy approaches very closely to the circle, and the two sorts of mallow leaves are of the same general contour. The water avens, or *Herba Benedicta*, from which the Early English foliage is said to be taken, gives a very simple trefoil; in late growth it is split into separate leaflets. The clover gives a very perfect trefoil, formed by three heart-shaped leaflets. The terminal point of the leaf of the sow thistle gives the triangle, which is seen again in the young leaves of the ivy. The ivy assumes three typical forms during its growth: the triangle, the square or lozenge, and at length, in its

full development, the pentagon. The terminal leaflet of the cow parsnip approaches closely to the diagonal square. The typical pentagonal form of palmate leaves is shown in the maple and sycamore. The five-pointed form is still retained by separate leaflets, as in the passion-flower leaf, and the cinque-foil. There are two modes of treating leaf-form. One, that of retaining the natural contour, as we find it more especially in older leaves, as in the maple and vine, which start off with an abrupt angle or curve from the leaf-stalk. The other mode is that as seen sometimes in young leaves, as in the hawthorn, where the leaf flows tangentially and smoothly out of the foot-stalk. Most of the conventionalised architectural foliage is in this manner, as in the early English. It is not necessary to follow natural leaves literally—they may be simplified; modified to make them more symmetrical, or altered to fill any particular form; or their outlines may be changed by adopting various cuttings, or differently formed lobes. If we take, for instance, the most common of all leaf-edgings, the serrated, we are not bound to the number we use in a leaf; we can reduce them to three, five, seven, and so on for the entire leaf, just as it may suit our purpose; or we can subdivide them as in the hawthorn, separate them by lobes, as in the *Grevillea Acanthifolia*, subdivide as in the creeping crowfoot; or lastly, separate into distinct leaflets, as in the delytra. The same rule applies to other edgings, and to the dentated and rounded forms, which may be also subdivided. Even the pointed forms may be softened into the rounded. What is done with leaves may also be done with flowers, or leaves may be substituted for petals. Variety of form may be also obtained by the introduction of insects, birds, animals, and the human figure, which frequently give additional interest to the composition with the happiest result. The light and shade of foliage is a matter of vast importance, and one that is seldom sufficiently considered. We can obtain but partial assistance in this study from nature. Carvers usually overdo the shadows on the surface of leaves. If they are engaged upon Gothic work, they will tumble the surface about like the sea in a storm, after the manner of the later Gothic carving, until all beauty of outline is lost. If it is a Classic leaf they are working upon, they will groove and hollow it up until the whole surface is full of lines. In my working drawings I always indicate the modelling of the leaves, which I usually keep very simple, but it is very seldom that I can get the carver to adhere to the simplicity aimed at. When carving is placed upon a ground, as in a panel, the treatment of that ground in high relief is of the utmost importance. In low relief the carving depends more upon outline, and not so much upon light and shade, because such works are usually placed near the eye; but in high relief the ground should be treated like the background of a picture, and the darkest and most intense tones be produced by it; the most brilliant lights should be obtained by the convex surfaces of the foliage, and the hollows be trusted to for the half-tints. With this scale of light and shade the artist has to work much in the same manner as a painter would if he were painting in monochrome. It is, therefore, important how the lights and shadows are balanced and distributed. If the shadows on the leaves are made too broad and deep, or too numerous, they must reduce the amount of light, and the value of the shadows on the ground will be destroyed, because they amalgamate with those on the surface. The conventional treatment of architectural foliage depends more upon the skilful management of the light and shade than upon almost anything else. In adapting, the forms of leafage may be followed very closely, but its geometrical distribution and the treatment of the light and shade are the principal means of transforming it into conventionalised architectural ornament. The amount of undercutting is another point which requires great consideration. Some carvers take an infinity of trouble, and laboriously undercut every part; but this is a mistake. Some portions do not require to be undercut at all, but should be made to unite and melt away into the ground itself, in order to soften the edges of some of the deepest tones, and to lose the outline of the minor parts, so as to raise the value and sharpness of others. By this mode of partial undercutting, also, we see that the work is actually a part of the panel, and not laid in. Where the work, however, is much raised from the ground it should invariably

be undercut, so as to avoid thick, clumsy edges to the leaves. We obtain many valuable hints for shadowing from the backs of natural leaves, as they are usually more convex than the fronts. The dried horse-chestnut leaf gives a very excellent suggestion for raising the centre of the leaf surrounded by a hollow, often of great use in practice. The artist also requires to study the general balance of his light and shade, so that one is not too important for the other. As a general rule he usually errs by creating too much shade. In this country we require strong contrasts, and if the work is internal, such as in a roof or grained ceiling, he can hardly make his light and shade too strong. The nature of the material in which the enrichments are executed is another matter requiring thought. A dull, heavy sandstone needs a very different treatment to a bright white crystalline marble, and deal has to be handled differently from oak, and box again, differently from either. Square block carving looks remarkably well in rough, coarse-grained sandstone; it has the advantage of never getting clogged up with soot, and it always shows to advantage when placed at a considerable height. For great heights very little surface carving is necessary, and foliage will frequently look all the better for being left perfectly square and flat, so as to give, according to the distance, the utmost value to the difference between the light and shade. What is crude and unfinished when near the eye will appear bright, sharp, and sparkling when placed at the height for which a due calculation has been made for the effect intended to be produced. Immense labour may be often saved by properly considering this point when designing or carving ornament to be placed at a considerable elevation. One way in which the amount of carving or intricacy of parts can be studied for various heights is this. Let the carver take his position on the ground in a position from which the enrichment can be best seen, after having set up a model at the height at which it is to be placed. Let him then with a pencil, stretched at arm's length, mark off upon it the size of the enrichment as seen from that point. If he puts this size upon paper, and begins to sketch in all the parts of his ornament as he intends carving it, he will soon perceive what to omit. If the height be considerable he will find that he cannot draw in all the work, and that he can improve the sketch by omitting half, or perhaps three parts of it. The principles upon which leaves are divided in nature are continually being intermingled, although the power of nature is so great that each individual plant retains its own characteristic form. Not so in art. After a considerable practice and study of nature, you will draw your leaves without immediate reference to nature, they will be in accordance with her laws, but one form will intermingle with another, until you will scarcely know yourself for what leaf you intend it. That, however, need not distress you, as your object is not to copy nature, but to work upon nature's laws. Thus your simple lilac leaf may become ternate, as in the Hepatica; doubly ternate, as in the creeping crowfoot; triply ternate, as in the celery; until, when you desire it, you arrive at the intricacy of the parsley, which is still upon the triple principle of division. Nature carries out the principle even upon the same plant—as in the ivy—where the leaves next the flower are perfectly plain and undivided, the young leaves upon the leaf stems are ternate, which further develop in the older leaves into a pentagonal form. The pentagonal principle is again carried on, from the ivy, through the maple, which has subdivided lobes, the vine and hop serrated, the cinque-foil where it becomes five distinct leaflets, and to the horse chestnut, in which it arrives at seven leaflets. You need not necessarily follow any particular leaf. One point more must be noticed—the foreshortening of finials and other objects when placed at a height on a building, and the necessity of proportioning them so that they appear to the eye of the desired height when in their elevated positions. Many sculptors make proper allowance for this when executing statues to be placed on the parapets and pediments of lofty buildings, but it is seldom attended to for minor objects. Some of the Early French finials are very ably proportioned in this respect, and here is an example, in which a due allowance has been made for foreshortening, in a finial from the interior of the Lady Chapel at Ely. It is from the upper canopies, where it is placed at a considerable height. It is greatly elongated beyond the ordinary proportion, and the berries

above the lower range of leaves are raised, and stand clear above them, although the modelling of the leaves is rather in excess; the ribs upon the surfaces are omitted. This elongation is not only observable in the finial, but also in the canopy itself, which is of a much more lofty proportion than any of those nearer the level of the eye. There are ample opportunities for introducing foliage into architecture, and abundant materials for the purpose of the artist in nature, which have never been exhausted—so that the source is a vast and boundless one, containing a never-ending variety of beautiful form. Nature, however, is so prolific, and so wayward in her manner, that a mere glimpse at a few leaves or flowers, or a mere picking up of a natural form here and there, is worse than useless. It is the principles that we have to search for, and these are hidden under every variety of form and manner. There is only one way to detect nature's secrets, and that is to sit down patiently to draw one form after another, until we at length arrive at a complete scale of all nature's variety of form—of her regularity and irregularity—of her geometrical uniformity, and of her apparent utter want of plan or design in her manner of growth. We see that throughout all her works she never by any chance imitates herself—for no two leaves, even upon the same branch, were ever yet found precisely alike—and yet the same forms are continually running throughout nature, until we may almost imagine that nature does nothing more than reproduce herself, and the casual observer can see but little variety in all her forms. Whether we examine natural forms in this country, or whether we obtain them from the most distant quarters of the earth, we can see nothing new, nothing fresh; nature is still at work upon her old forms, at one time on a gigantic scale, at another upon a microscopic one; but when we search below the surface, we arrive at certain art principles upon which nature works, and which alone are of any worth to the true artist. There is more truth in the words of the poet than he himself knew, when he said—

All nature is but art, unknown to thee;
All chance, direction which thou canst not see;
All discord, harmony not understood;
All partial evil, universal good.

Mr. HADFIELD, of Sheffield, proposed a vote of thanks to Mr. Colling, with most of which he cordially concurred. The architect who insisted on having all his bench ends carved to a uniform pattern, could not have been a very attentive student of old Gothic work; in our churches there is much variety in the treatment of the ornament, and frequently the decoration has some reference to the dedication of the church, or to local or family history.

Professor KERR, in seconding the vote of thanks, paid a tribute to Mr. Colling's long continued studies and working on carved foliage. It was a subject extremely difficult to reduce to anything like philosophy, and even the author, with all his numerous examples and patient investigations, had not ventured to evolve laws on which to work out the treatment, but led his hearers to nature and there left them. There were one or two points he would like to raise, without differing from the lecturer. One of these was the scale of objects imitated from nature; was it permitted to the carver to vary this or ought he to adhere to the various sizes of the objects copied? It seemed to him that if one took, say, a leaf of parsley, dock, or thistle, or the smaller trefoil clover as a model, he was scarcely at liberty to reduce or enlarge all to the same size. In imitating it was assumed that nature's objects were perfect and her scale was a part of the design. At the same time, various scales might be employed on different architectural works. Perhaps Mr. Colling would overcome this difficulty by regarding the scale of his decoration as conventional, but in going a step further back one might encounter a greater difficulty in assimilating forms one with the other. Another point was that if carvers were to imitate nature in stone, how could they copy natural leaves to a nicety in such a material? It did not seem a substance in which the tissues of leaves and plants could be appropriately reproduced in all their minuteness. Carved foliage should be essentially architecturalesque and conventional in character. In carving on boxwood or ivory the treatment might be delicate and dainty, and natural forms might be copied exactly as one found them; but for ornament to be applied to architecture, conventionalism was of the essential philosophy of the work. Thus the Greeks usually

conventionalised the foliage when applied to buildings. In Mediæval carving, especially of the 13th century, there was an exquisite nicety; it was more *naturalesque*, but still everything was conventionalised, much more so than was usually the case at the present day. He was very glad to hear Mr. Colling condemn all "festoons and swags" for the system on which they were designed was fallacious. Those who were the masters of the Queen Anne style were compelled to use these festoons, and to develop them in red brick—a marvellous instance of what man will do when working upon fallacious principles. No allusions have been made to this, probably because Mr. Colling had kept upon higher ground. Another point of interest was the proper architecturaesque carving upon terra-cotta. There were two principles on which terra-cotta might be ornamented. On one the material was taken from the mould, burnt in the kiln and then treated; on the other it was sophisticated, trimmed, modified, undercut, and otherwise treated in the process of manufacture after it had come from the mould. These two modes of treatment were suggestive of the question whether the material should be regarded as to be cast or cut, and the same query also arose as to plaster-work generally.

The President remarked that the paper was suggestive, but the subject was subordinate in its relation to the work of an architect. The architect's first consideration should be not the treatment of surface, but the general form and proportion, and so to assimilate the features to the character of the building. Mr. Colling had spoken against wasting time upon the study of mouldings and proportions of old work, but the difference between the work of the skilled artist and the mere stucco constructor lay chiefly in the greater care bestowed on his details and outlines shown by the former. Other differences between cultured and uncultured work existed in the greater power to observe natural forms and skill in reproducing the features selected—two qualities not found in constant ratio amongst different workers. He would venture, even pace Messrs. Colling and Kerr, to make some apology for the much-abused festoon. It generally represented flowers not growing, but plucked, and might thus be appropriately hung in panels or placed on pediments. He was not sure that Mr. Colling had been quite consistent in his paper, for he seemed to argue in favour of a natural treatment of foliage in one place, and in another that it should be made more conventional than was usual.

Mr. COLLING, in reply, said there was no necessity to adhere to any set scale in the imitation of natural objects. Nature herself varied the scale in warmer or colder climates, as might be seen in hot-house foliage. Again, one might take a part only of an object as a decoration—a single portion of the parsley-leaf would generally be found better than the whole spray. Neither scale nor form should be followed to a nicety, but every detail should be studied direct from nature, and then broadly conventionalised. The President had rather misunderstood him as to mouldings; he did not object to their being studied or used, but to their being substituted for carved decoration. His chief objection to festoons was that they represented decoration external, and applied to the building, and that they did not form part of the architecture. He did not object to conventional foliage, but to the resuscitation of conventional foliage of other days, whether Greek, Roman, or Gothic; instead of this, let them go back to nature and conventionalise from its forms for themselves.

The President announced that the next meeting would be held on April 21st.

MR. SEYMOUR HADEN ON ETCHING.—II.

THE theatre of the Royal Institution was closely packed on Saturday afternoon by those desirous of witnessing Mr. Seymour Haden's demonstration of the mode in which he etches. The lecturer said he should divide the subject into three parts, and should in turn consider the art itself, its chemistry and its mechanics, the last including its material results.

There are three modes, he said, in which one can deal with a metal plate so as to print from it, viz., those of engraving proper, etching proper, and dry-pointing—a process which may be regarded as intermediate between the other two. Engraving is executed by actual delving into

certain portions of the plate by means of an instrument having a triangular point, and called a burin. In etching a corresponding portion of the plate is removed, not by cutting into the material, but by the action of certain chemical agents known as mordants, which are allowed to act on unprotected portions of the plate. The dry-point process consists in incising lines and afterwards roughening the same by means of a sharp style, without, however, removing any of the surface. My purpose is not only to explain the ordinary process of etching, but also to describe a process which few have heard of, and which still fewer have employed. Ordinary etching consists in drawing upon a plate previously protected by a resinous coating with a needle, in such a fashion as to remove the coating and lay bare a portion of the metal. The needle is not intended to wound the metal, but simply to remove the varnish with which it has been coated. The next operation is to submit the plate to the action of a chemical agent having a strong affinity for the metal—in technical terms, capable of "biting it." This biting can be effected in two ways: either by means of nitrous acid, stopped out from the portions not to be corroded by Brunswick black, or by chlorate of potash in diluted hydrochloric acid. The ordinary process of etching is so troublesome an affair that it may well deter anybody from attempting it. The work is so awkward, and difficult of execution, as to certain classes of minds to prove prohibitive. The plate is first varnished on both sides, so carefully as to completely protect it from the mordant. Then the drawing is made upon it in lines of equal thickness by means of a long needle. When the design is completed it is well-nigh incomprehensible; the strokes in the extreme distance are exactly the same as in the foreground, and none but an adept could make head or tail of the plate. The artist next examines his plate, and, with a brush charged with varnish, lightly covers over, or, as he calls it, "stops out" any lines which may appear to him to be wrong; then he puts his plate—such a one as the one already drawn upon which I have in my hand—into the bath already prepared. In about a quarter of an hour I shall have to take out and examine the plate, and stop out those portions which I think are sufficiently bitten by the mordant, and this must be done at frequent intervals throughout the biting operation to obtain the varied effects of distances. You will understand from this that the process is a most laborious process, and indeed it could not be completed within the limits of an ordinary lecture, so that I could not show the whole in operation. Then, at the end of it all, it will be found that, owing to the imperfect nature of the mordant, the biting has been very irregular, and it frequently becomes necessary to enforce parts of the etching not properly bitten with a stronger mordant. This accomplished, the varnish is cleaned off the plate, and the plate is ready to be printed from. Even now, after all the varnish has been cleaned off, it may be found that the plate has not been sufficiently bitten, owing to the temperature having been too low, or some other reason. In such a case a very delicate process must be resorted to; a dabber, covered with varnish, is applied to the surface of the plate so cautiously as to protect the general face, but not to fill in any of the lines insufficiently bitten; and it may be imagined what a very gentle hand is needed for this. The plate is then returned to the bath and finally re-bitten.

Another process, that which I have the credit of having invented—a statement partly true and partly incorrect—I have ventured to call the "continuous process," in distinction from the one just described—the ordinary or "interrupted process." In this new method the execution of the drawing on the plate is effected while it lies in the mordant bath. The drawing is so carried on that the lines described first shall be the ones requiring to be the most bitten, and the last those that need the mordant action least, so that there is a regular and imperceptible gradation of intensity from the immediate foreground to the aerial perspective. Sometimes it is inconvenient to draw while the plate is immersed in the mordant. This is never the case in the open air or in a room lighted from the side; but it is extremely inconvenient in such a building as this theatre, lighted entirely from a lantern, and in order to demonstrate my process I shall therefore have to avail myself of the aid of artificial light. Under the ordinary process the drawing

is executed in several stages: beginning at the foreground, the etcher works in the middle distance, the extreme distance, and then the sky, biting in each stage with the mordant as he proceeds, and stopping out those fully bitten. The etching lines thus form a series of different planes of depth. But in the continuous method the biting is proceeding concurrently with the drawing, so that each line has its peculiar intensity, and the result is an etching really "coloured" by lines of different thicknesses. The metals used for etching upon are zinc and copper. Steel is used by engravers, but never by etchers on account of the hard and dry line it makes; for this reason it is unpleasant, and therefore undesirable. Copper, on the other hand, is sometimes soft and at other times hard, and that makes a great difference in the value, endurance, and execution of the plate. I very rarely etch upon it, although its use is very common. The line made on steel is hard and inartistic, that on copper is soft, while that on zinc is very flowing and painter-like. The impression from zinc is totally different from that on copper (as may be seen from these proofs hung side by side); the lines are broader, have more colour, and have a more artistic result, although those on copper are undoubtedly more delicate. [Mr. Haden here drew attention to a series of his framed drawings hung on the screen, pointing out that some were etchings on copper and some on zinc, executed by the interrupted and continuous process; some were examples of dry-pointing and others of ordinary engraving.] Zinc is very speedily bitten, so that I shall be able to execute and finish a drawing under the continuous process in a quarter of an hour, whereas, if I drew on copper, it would occupy an hour. Before coming to the room I put a zinc plate into a bath of water, hydrochloric acid, and chlorate of potash, and tried the experiment of drawing for exactly a quarter of an hour to see how far one could get; I found I could etch to half through the middle distance, and with your permission I will continue the experiment. Here, you see, is my bath; at the bottom are four little bits of wax, on which the back of the plate will rest. On this plate, which is already varnished, there are a few marks (although perhaps you cannot see them). The solution in the bath into which I am dipping it is stronger than it would be exactly prudent to use for actual work, but that will render the process both quicker and easier. You will please to imagine that you are looking out of a window at Amsterdam. Immediately in front is the river Amstel; on the left is a row of trees and between the two a road. In order to remove the varnish from the plate I am using a very coarse piece of steel; it does not need a fine point, for the mordant keeps it sharp. Of course the nearest objects must be drawn first, and I will begin with a tree (Mr. Haden proceeded to draw as he explained the operation). Now we will go on to the next tree, and then to the one next to that, each being one degree further back than the one last completed. In the river, are some barks of timber floating about, and on one of them is a man fishing; all these things are useful as proving that it is a river we are looking at, for each must be indicated with a few strokes. In the middle of the river is a boat in which is a mast, and in the boat are two men, and there are one or two posts in the river. The lines composing the road come next, but the road is dusty, and the ruts must be left till later, for they belong in depth of execution to the background. On the other side of the river are some trees forming in fact the middle distance and background, and a few white houses peep out; these trees may be suggested by a few lines, but the windows of the houses must be kept black. There are two or three boats in the middle distance, and by the river some trees with very deep shadows under them, especially between the stumps, which stand out from the shadows. If you listen to my needle you will hear a distinct grating noise; it is being arrested by the action of the mordant, and this is very valuable aid to the etcher; for, one thing, he cannot easily transgress upon a line already drawn, owing to the biting of the mordant. This plate is undergoing the action of what is called "foul biting," the coating of varnish is not sufficient to cover it, and the mordant will act upon the general surface. This accident would be the despair of an engraver, but an etcher rather likes it, as it gives colour and effect to his print. By this time our first plate, done on the intermittent process before I came here, is partly bitten, and you

see that I remove it from the bath, and stop out portions of it with varnish. It represents a country lane, deeply rutted, and you observe I have almost covered it with fresh varnish, all except a post in the middle which I want to stand out, and so I leave this to be further acted upon in the bath. But it becomes necessary for me to describe the chemistry of what is going on. This depends on the biting in of the unprotected parts of a metal plate, by the action and reaction of chemical agents. For copper, we use (a) nitrous acid 33½ parts, and water 66½ parts = 100 parts; and (b) hydrochloric acid 20 parts, and chlorate of potash 3, adding of water 77 parts = 100 parts. We (1) dissolve the chlorate of potash in 38 parts of boiling water, and (2) mix the hydrochloric acid with the remaining 38 parts of cold water, and (3) add the two solutions together. For zinc we use (a) nitric acid 25 parts, and water 75 parts = 100 parts; and (b) hydrochloric acid 10 parts, and chlorate of potash, 2 parts, adding of water 88 parts = 100 parts. The solution is made in the same way as for copper. By experiment the lecturer explained the method of making nitric acid, and added that the action of this agent on copper is extremely uncertain as well as long. The biting-in is really equivalent to the painting-in or technical execution of the picture, while the actual work with the needle corresponds to the art manifestation or poet side of the production of a picture. Now the actual painting-in of a picture is a very serious thing; upon it depends the whole spirit and sense of the work. Some artists have the power of conception, and others only the art of execution; but only in extremely rare instances are both gifts combined. Palmer has both, and so has Merion, but Whistler shows only one; while Herkimer and Hook possess both in a fair degree, and almost every other etcher has only the one quality. Turner had the power of biting-in the line in a manner unlike that of any engraver. In his "Liber Studiorum" the engraver was to finish the plates, but in some cases Turner completed the biting, and in these the work is a model of skill and mastery; every line is distinct, and there is not a line too much. Two or three were drawn but not bitten by Turner. Thus there are two plates of a "Farmyard," both drawn by him, but only one bitten by Turner; and you can hardly believe that the two were executed by the same person, so great is the individuality which resides in the biting-in. Returning to our etching, I may say that etching in a mordant, under the continuous process, is a pleasant process; if you have a low stool and sit in the open air, it is almost like painting on an easel. Nitric acid is always unmanageable—partly on account of varying atmosphere, hygrometric, or meteorological conditions, and partly because of the impurity of the substance. Etchers often find that on certain bright, sunny days, when all other conditions are favourable for his work, the acid will not bite; whereas on a lowery, gloomy day its action is very rapid. The reason for this is the presence of more or less oxygen in the air, assisting or retarding the galvanic action of the nitric acid on the copper. The several reactions I have drawn out as a diagram,* which it would be well for every etcher to copy and study at his leisure.

The third head, that of the mechanics of etching, remain to be considered, and by this term I mean the material results of the process. In Fig. 1, you will see a section of the depression caused in the copper by the mordants. For a time the surface resists the acid, but when it has bitten it, the mordant spreads in every direction beneath the surface, forming a more or less globular cavity; above this is a little pent, or roof of varnished surface, and this plays an

important part in the durability of the plate. Now, with this, let us compare an engraved line (Fig. 2); you will see that the triangular

point of the burin has scooped out an accurate straight-edged groove. You see at once that the burin is a most inartistic instrument; it was never used by Martin Schön or Albert Dürer. Lucas, Vanleiden, and many early engravers employed it, but never invented with it, for they could not. The burin may be suited for reproduction, but has no artistic value. When the printing ink is passed over the surface of an engraved plate, it forms a V shaped line on the paper. The cast of an etched plate is totally different (and I believe this distinction has never before been pointed out). The etched cavity has much more retaining power than the engraved groove, and the surface of the impression is rounded. For these reasons, an engraving has a hard grey effect, while the masses of an etching have a colour and richness of their own. The durability of an engraved and of an etched plate is again very different; from the former thousands of proofs may be taken, but from the latter only a few are obtainable. Why is this? Because, while in each case the wear of the handling, and the pressure of the roller and machine are much the same, grinding down the whole surface of the plates, its effect on an engraved plate is to remove the upper part of the groove you see in section, and consequently to narrow the burin cut. As a consequence, the impression of these lines grows very slowly paler and paler, until at last it has no colour. In the etching, however, the pressure upon its characteristic pents over the holes left by the acid, very soon breaks them down, and the whole of the crater is open, and the result is, that after printing 40 or 50 proofs, you find it has got so muddy that you don't care about it. But, before we close, I must clear off the varnish from our plate, and you will see to what extent it has been bitten. In our next, and last lecture, we will go into the process of printing off our etchings, and we shall have a little press, and print them off in this room.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

KING ALFRED'S SUMMER PALACE.—The excavations in King's Court-yard, at Mudgley, Wedmore, near Bridgewater (where the thousandth anniversary of the peace of Wedmore was recently celebrated), for the supposed remains of King Alfred's Summer Palace, are progressing satisfactorily, under the management of the Rev. Sydenham Hervey. Of late much more of the supposed palace of the West Saxon kings has been brought to light. A wide stone causeway at the north entrance of the palace has been found. Its length is not yet known. A well little less than 30ft. deep has been discovered at the south side of the works. It is supposed that another well will be opened shortly more towards the interior of the building. The excavators are now opening the ground on a wide and long wall, leading from south to north at the west side of the field. The width of the wall varies considerably, and one end of it seems more like a double wall than a single one. The north end of it is not yet reached. This wall is an important discovery, as it somewhat corresponds with the wall at the east end running parallel with it in the same direction. A better plan of the building can now be drawn, and a more exact description given. The masonry in this wall and in the wall of the well is more perfect than any yet found.

Extensive works of restoration and repairs are about to be carried out at the parish church of Shenington, near Oxford, from the designs of Mr. J. L. Pearson, A.R.A., of Harley-street, W. The chief features of the work will be a new roof, new pews in the place of the present high ones, a new vestry and organ chamber on north side of church, fresh stalls and tiling in the chancel, and providing a heating apparatus. Tenders have been invited from selected builders, and that of Mr. Bartlett, of Bloxham, being the lowest, has been accepted at £1,200.

BOOKS RECEIVED.

The City of London Directory, 1879 (London: W. H. & L. Collingridge), is marked by several improvements which add to its value. It has a position as a directory which is unique in the variety and accuracy of the information given, which is absent from any other work of the kind we know of. To City men it has long become indispensable. — *Bevis's Builders' Price Book* (London: H. C. Bevis & Co.) is a guide for estimates, arranged by Mr. H. C. Bevis, whose practical experience as a builders' accountant has again been turned to good account in its preparation. — *A Universal Dictionary for Architects, &c.*, by Wyvill James Christy (London: Griffith and Farran), is to be a "copious vocabulary and practical explanation of the usual terms current in the architectural profession and allied trades." The first part only is to hand. The assumption in the preface that "excepting the Dictionary of Architecture there is no book which exclusively contains in alphabetical order a fair approach to a complete repertory of architectural and building artificers' phraseology" is inaccurate, and the attempt made to supply the want not so successful as might be wished. The dictionary is "copious" enough, but not complete. For instance, it is not possible to give any practical information worth having about abattoirs in the space of eleven lines. More space might easily have been gained on the same page by omitting the twenty lines devoted to the explanation of "Abbreviations," which are of no practical value whatever. We scarcely see, either, why it was necessary, on p. 43, to introduce the word "architectress" merely to tell us at the end of thirty lines that it is scarcely probable "that women will ever sedulously cultivate any architectural talent." — *Familiar Garden Flowers*, by Shirley Hibberd and F. Edward Hulme (London: Cassell, Petter and Galpin), will have its principal value for our readers in the plates, which are designed by an artist who has before contributed to our own pages. — *The Carpenter's Slide Rule: Its History and Use* (Birmingham: John Rabone & Sons), is a cheap and very complete series of instructions useful to builders, carpenters, bricklayers, glaziers, paviors, slaters, &c.

CHIPS.

New steam flour and meal mills were started at Keswick last week. The building is 90ft. by 35ft., and six stories in height, and has been constructed of local red freestone, from the designs of Mr. W. N. Dack, C.E., of Patricroft, Manchester. The machinery is chiefly from Illinois and Hamburg, and is driven by rope gearing in place of the usual upright shafts and beveling. Mr. Dixon, of Penrith, was the contractor for masonry, and Mr. Pattinson, of the same town, for the joinery.

A new aisle is about to be added to Christ Church, Lowestoft, from the designs of Mr. W. Oldham Chambers, of that town.

A stained glass Perpendicular window has been placed on the north side of Great Shelford Church, Cambridge. The principal subjects are the three Graces—Faith, Hope, and Charity—while the tracery is filled with angels and lily foliage. The work was designed and executed by Mr. W. H. Constable, of London and Cambridge.

The new thoroughfare known as the Bethnal-green Improvement, being the last portion of the Oxford-street to Old Ford line of new streets, sanctioned by Parliament in 1872, was opened by the Chairman of the Metropolitan Board of Works on Friday afternoon. The new street is 60ft. wide and nearly 2,000ft. in length, and is carried from near Shoreditch Church to the wide portion of Bethnal-green-road.

An inquiry was held at Ryde, Isle of Wight, on Wednesday week, before Mr. G. S. Smith, C.E., Local Government Board Inspector, respecting an application from the Town Council for power to borrow £12,000 for the extension and improvement of the esplanade.

Mr. G. E. Street, R.A., has resigned his seat on the council of the Royal Institute of British Architects (of which he is one of the vice-presidents), owing to the large demands which will be made on his time at the council of the Royal Academy during the next two years.

A new chapel-of-ease is about to be erected at Burton-on-Trent, to accommodate 600 people, at a cost of £5,000. Mr. R. Churchill is the architect and Messrs. Lowe and Sons the builders.

Thomas Couture, the French historical painter, died on Monday, in his 64th year. His chief picture, entitled "Romains de la Decadence," figured in the 1855 Exhibition.

* 1. Reaction of copper on nitric acid in two simultaneous steps. The copper acts on nitric acid, forming oxide of copper, and with water, forming nitric oxide:

2. Reaction of copper and zinc on a mixture of chlorate of potash and hydrochloric acid. "Dutch mordant" may, though simultaneous, also be represented in two equations:

The green chloride remaining in solution. For zinc:

Building Intelligence.

METROPOLITAN BOARD OF WORKS.—At this board on Friday a resolution was passed declaring it desirable that the opening up of Buckingham-street to the ornamental garden of the Victoria Embankment should be carried out by the raising and opening of the York Water Gate, and it was referred to the works committee to suggest the mode in which this shall be carried out. An offer from the French Electric Light Company to supply two more electro-dynamic machines so as to supply 20 additional lights, extending along the Victoria Embankment as far as Blackfriars-bridge, at the inclusive rate of 6d. per lamp per hour, was accepted. Sir J. W. Bazalgette stated, in reply to questions, that the electric light became more feeble if more than a certain number were lighted, but that at present the engine was not working to its full power. It was stated that experiments were being made by the officers of the board, the result of which would be embodied in the report to be hereafter published. A letter was received from the Home Office, transmitting a statement of objections signed by Mr. J. Goodman, as chairman of a meeting of owners of land, and builders, and urged by such meeting against certain by-laws proposed under the Metropolitan Management and Building Acts Amendment Act, 1878; it was referred to the Building Act Committee.

RAWMARSH.—Last week the first school which has been erected by the Rawmarsh School Board was formally opened. The new schools have been erected at a cost of £6,200, and will accommodate 700 children. Mr. J. Platts, of Rawmarsh, is the architect. The schools will accommodate 200 boys, 150 girls, and 350 infants, allowing ten superficial feet of space for each child. The style is Domestic Gothic. They are built of brick, with Hooton stone dressings, and the three main fronts are faced with pressed bricks. Mr. Joseph Brookfield, of Parkgate, acted as clerk of the works.

SOUTHAMPTON.—The corner stone of the new Freemasons' Hall at Southampton was laid last week. The principal elevation of the hall, which is to be in the Italian style of architecture freely treated, is 50ft. in length, the side elevations, facing the Forest-view roadway, extending about 73ft. There will be an ante-room or chapter-room, 26ft. 4in. by 18ft. 9in., with a height of 11ft., its bay windows overlooking the Western Shore. The lodge-room will be 45ft. by 30ft. and 18ft. high, and will be lighted by two lanterns from the roof. There will be a banquetting room, facing Albion-terrace, 38ft. 6in. by 25 ft., also 18ft. high, together with a kitchen, wash-house, pantry, and serving passage. The material will be of white brick in all the exposed parts, with dressings partly in moulded brick, and of stone to the architraves and pediments. The roofs are to be slated and tile capped. The architect is Mr. J. G. Poole, and the builder Mr. S. Stevens, both of Southampton.

By the death of Mr. G. F. Playne, F.G.S., of Minchinhampton, the county of Gloucestershire has lost an archaeologist, botanist, and geologist of distinction. The Gloucester Museum is indebted to him for an excellent collection of flint implements. In collecting materials for one of his last papers—read at the Cottswold Club, on "The Ancient Camps of Gloucestershire"—he visited, and from measurement made plans of nearly every camp in the county.

Mr. J. Louth Clemence, architect, of Lowestoft, has been appointed surveyor to the Kirkley Burial Board.

In our account of the restoration of the parish church of Kennardington, Kent, last week, the Incumbent's name is misprinted as Loft instead of Lobb. The contractors, who have very satisfactorily carried out Mr. Seddon's designs, are Messrs. Bourne and Son, Woodchurch, Kent.

Those interested in the preservation of the Carlisle Tower, Newcastle-on-Tyne, ancient landmark, will be pleased to learn that it is the intention of the Treasury to send down an inspector to examine and report to their lordships upon the question at issue.

A memorial pulpit to the late vicar, the Rev. C. Porter, constructed wholly of English oak from designs by the late Sir Gilbert Scott, has just been placed in the church of Raunds, Northamptonshire.

More than Fifty Thousand Replies and Letters on subjects of Universal Interest have appeared during the last ten years in the **ENGLISH MECHANIC AND WORLD OF SCIENCE**, most of them from the pens of the leading Scientific and Technical Authorities of the day. Thousands of original articles and scientific papers, and countless receipts and wrinkles embracing almost every subject on which it is possible to desire information have also appeared during the same period. The earliest and most accurate information respecting all new scientific discoveries and mechanical inventions is to be found in its pages, and its large circulation render it the best medium for all advertisers who wish their announcements to be brought under the notice of manufacturers, mechanics, scientific workers, and amateurs. Price 2s. 6d. of all booksellers and news-vendors. Post free 2s. 6d. Office: 31, Tavistock street, Covent-garden W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 6s.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 33s. 30c.). To India (via Southampton), £1 6s. 6d. To any of the Australian Colonies New Zealand, the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

N.B.—American and Belgian subscribers are requested to remit their subscriptions by International P.O.O., and to advise the publisher of the date and amount of their remittance. If the last-mentioned precaution is omitted some difficulty is very likely to arise in obtaining the amount. Back numbers can only be sent at the rate of 7d. each, the postage charged being 3d. per copy. All foreign subscriptions, unaccompanied by an additional remittance to cover the extra cost of forwarding back numbers, are commenced from the next number published after the receipt of the subscription.

Cases for binding the half-yearly volumes, 2s. each.

GOOD FRIDAY.

The next number of the BUILDING NEWS will be published on Thursday, April 10. All advertisements and other communications must reach the office by 5 p.m. on Wednesday, April 9.

RECEIVED.—B. C. B. I.—J. and W.—W. A. W.—P. and S.—C. P.—B. and Son.—E. M.—J. C.—L. W. R.—D. F. Co.—W. and H.—W. G.—G. B. and L.—R. L.—N. P. B. of E. S.—G. H. C.—C. and G.—D. and Co.—S. and Co.—J. J. C. and Co.—G. S. Bros.—S. L.—T. P. L.—J. McD.—H. J. and Son.—F. B.

A. J. FAYES. (The engineer to whom he is article will do it if he enters his office at an early age, meanwhile he should join the classes of construction and design at a science school.)

OLD HOUSES AT EXETER.—(Geo. S. Penny, 14, Rodney-terrace, Cheltenham, has sent us some interesting photographs of the old houses on the bridge at Exeter, described by Mr. Hems in the BUILDING NEWS last week. We cannot undertake to reproduce the photographs, but we believe copies can be had of Mr. Penny.)

Correspondence.

CONCRETE PIPES AND BOURNEMOUTH DRAINAGE.

To the Editor of the BUILDING NEWS.

SIR,—The letter of your correspondent, "A. C. P.," on the above subject, in your issue of the 22nd inst., contains grave mis-statements, and a disingenuous manipulation of figures calculated to mislead.

We should take no notice of a strictly anonymous communication of this description, but inasmuch as your correspondent's initials are also those of the Mr. Ponton whom you refer to in your leading article, and who was employed by the Bournemouth Commissioners, we feel bound to point out the coincidence, as your correspondent ignores it, and the pamphlet also.

We thank you for your impartial review of our brochure, and trust that those of your readers interested will acquaint themselves with the facts on both sides, by procuring the publi-

cation, which includes Mr. Ponton's own report. It can be had of Messrs. Spon, or of your obedient servants,

HENRY SHARP, JONES, AND CO.
Bourne Valley Pottery, Poole, March 31st, 1879.

CONCRETE PIPES AT BOURNEMOUTH.

SIR,—The letter of your correspondent, "A. C. P.," read by the light of your leading article on the same subject, is decidedly instructive.

It needs no very great exercise of perceptive power to discover in the initials "A. C. P.," the Mr. A. C. Ponton mentioned in your article, and while he says that "some other tests were made, not on behalf of the manufacturers, and these tests did not give so favourable results," he omits to add that these other tests were made on behalf of the Bournemouth Commissioners by himself and Mr. Donaldson.

I cannot understand how "A. C. P." arrives at the conclusions he gives. I have read the pamphlet published by Spon, and with some difficulty I find the thirty-five tests that he first gives, but he has mixed them up in such a manner as to deprive them of value for or against.

He also states that the briquettes had a 2 $\frac{1}{2}$ sq. in. breaking section, but I see the book gives them as one square inch section—a vital difference.

Your correspondent does not refer in any way to the famous theory which Mr. Ponton propounded for the first time in the interests of the Bournemouth Commissioners, viz., that the pure water of this neighbourhood destroys Portland cement concrete. But, perhaps, after all, I am mistaken, for I cannot think that a "F.R.I.B.A." would act so unprofessionally as to attempt to prejudice a case in which he had been engaged by an anonymous letter, and in the manner above described.—I am, &c.,

A MEMBER OF THE ASSOCIATION OF MUNICIPAL AND SANITARY ENGINEERS AND SURVEYORS.

Intercommunication.

QUESTIONS.

[5720].—**Sketching Tour.**—Will someone kindly tell me in what pleasant country district in England I can best spend two or three weeks on a pedestrian architectural sketching tour with the principal towns that I should visit? Also the name and price of the best guide-book for my purpose.—S. R. A.

[5721].—**Damp in Basement.**—Will any of the readers of the BUILDING NEWS kindly suggest a remedy in the following case:—In the basement of a suburban house, the floors of which are of cement or compo-work, the water by some means forces itself through the floor in certain places periodically (especially after heavy rain), and although the occupier has had the places repaired with Portland cement, the water still percolates through as before. It is ascertained not to be caused by the drains, which are in good order, but is evidently the surface water. The cause and remedy will oblige.—R. M.

[5722].—**Dilapidations.**—1. Under what circumstances can repointing to external brickwork be required under the usual general covenants of a lease? Is it anything to do with the age of the premises? 2. When an old party wall is condemned by the district surveyor, and the adjoining premises are held on a lease containing the usual repairing covenants, but only a few years remain unexpired, what are the legal responsibilities of the lessee in the matter? An answer to the above questions will oblige.—TWEEDIE.

[5723].—**Floors.**—Would some practical reader kindly inform me as to the best methods for deadening the sound arising from ground floors in school-rooms? Also as to the merits of wooden blocks laid in cement, with a description of materials and the approximate cost of each method.—NOVICE.

[5724].—**Queen Anne Buildings.**—I am intending to visit London this Easter, and would be obliged if any of your readers would give a list of the best specimens of modern Queen Anne buildings. This information may be useful to others.—HENRY BARNES.

REPLIES.

[5709].—**Perspective.**—ERRATA.—In last week's reply, 14th line, for "span" read "show." 30th line, for "assured" read "assumed." 71st line, for "turn" read "from."—H. A.

[5711].—**Cricket Pavilion.**—I should have written an answer to the question asked by "Country Wickets" but that all I could say appeared so much like a shop advertisement that I abandoned the idea. However, if "Country Wickets" will put himself in communication with me I shall be glad to show him the drawings mentioned, and, if necessary, he can have a copy of the cricket pavilion. You were kind enough to give us (Mr. Robertson, my lato partner, and myself) a very favourable report on our Roundhay-park plans which we appreciated very much. We were not successful in taking any of the premiums, and most of our plans were spoiled before they

were returned, and all were sent back in a disgraceful state. We ought to get quite used to had treatment in competition matters.—J. J. STEWART, Architect, Wool Exchange, Coleman-street, Bank, London, E.C., 2nd April, 1879.

STATUES, MEMORIALS, &c.

THE GROSSER KURFÜRST MEMORIAL.—The design for the memorial which is to be erected in Folkestone cemetery in memory of the sailors who were drowned on the occasion of the foundering of the Grosser Kurfürst in May last, has been submitted to the Folkestone Burial Board and received its approval. The principal material used will be yellow sandstone, and for the ornamental enrichment and purposes of inscription bronze will be utilised. The top part of the design is of a pyramidal shape resting on a superstructure having for its base a slab of granite. The various emblems consists of cypress leaves, palm branches, wreaths of oak leaves, garlands, the arms of the Imperial German Navy, and the German ensign. The height will be about 19ft.

WATER SUPPLY AND SANITARY MATTERS.

DISS.—A Local Government Board inquiry was held at Diss, Norfolk, on Tuesday week, before Major Tulloch, relative to an application from the Local Board for sanction to a loan of £1,500 for carrying out works of sewerage by the urban sanitary authority. The plans produced and explained have been prepared by Mr. Charlton Walleston, C.E., and provide for carrying the existing sewers into a meadow in the parish of Palgrave, near the river Waveney, where it will be utilised for irrigation of 2½ acres of land. Objections were raised that the scheme was not sufficiently comprehensive, and that the proposed site would be a nuisance, but the inspector, after visiting the meadow and the suggested alternative sites, expressed his opinion that the works did not injuriously affect Palgrave, but that more land should be included in the scheme.

WATER SUPPLY OF LONDON.—An adjourned meeting of delegates from the vestries of the metropolis was held last week, in the Vestry Hall of St. Martin's-in-the-Fields, to consider the best means of improving the water supply. Mr. Edward J. Watherston was in the chair. About 24 vestries were represented. The chairman said that the most serious matter for the consideration of the ratepayers of the metropolis and the consumers of water was, not alone the increased and rapidly increasing value of the properties of the several water companies, owing to the principle upon which they were legally entitled to make their charges—upon annual value, with extras for high service, water-closets, and fixed baths—but also the reduction of a largely unremunerative expenditure, and the prevention of its continued augmentation by outlays for unnecessary works. Another matter of considerable interest to Londoners was the prevention of loss of life and property by fire. The work before them was to stop the growing power of the monopolies. In order to show the enormous and rapid growth in the rateable value of metropolitan property, he read a table showing the increase that had taken place in 30 parishes, where the values had risen more than 100 per cent. in the 20 years ending 1876. Among the most striking cases were those of St. Mary Abbott, Kensington, where the increase was 421·3 per cent.; St. John, Hampstead, 323; St. Mary, Battersea, 319·5; St. Mary, Stratford-le-Bow, 338; St. Leonard, Bromley, 301·8; Lee, 327·4; Penge, 338·3; and the Charterhouse, 444·8 per cent. The average increase in the rateable value was 104·7, showing a total increase of £11,827,650 in 20 years. Thus it had come about that the properties of the several water companies, which in 1856 were worth six millions sterling, were now roughly estimated at 26 millions; and unless a stop were put to their growing powers, they would before long be worth 35 millions. The work of the present committee would be to propose a scheme which, while it should be fair and just to the present holders of water stock, should be satisfactory to the general body of consumers. In conclusion, he held that the existing arrangements for supplying the metropolitan district with water were defective; 2, that the defects were not merely of a temporary character, but were inherent to the system upon which the existing arrangements were based, so as to be permanently detrimental to the public interests; 3, that it was absolutely necessary to remedy those defects in order to secure a better supply of pure and wholesome water, to be distributed under the constant system, and with such pressure and with such hydrant arrangements as would render it available at a moment's notice for the purpose of extinguishing fires; 4, that this could only be accomplished under a system of unity of management; 5, that from the economies possible under such a system, such alterations as might be necessary in the house services should be made, not at private, but at public expense; and 6, that

in the absence of a municipal corporation, or of any representative body willing or competent to undertake the consolidation of the works, it was requisite that this should be accomplished by a special water commission, responsible to the Local Government Board. A resolution to the effect that the chairman's speech should be printed and circulated was carried after some discussion, in which such strong opposition was shown to the suggestion that the proposed commission should be under the control of the Local Government Board that the chairman consented to withdraw the obnoxious clause, and the resolution was then agreed to. A resolution expressing the concurrence of the delegates in the views of the chairman on the principal points set forth in his speech was passed, and the meeting adjourned.

LEGAL INTELLIGENCE.

ARCHITECTS' CHARGES.—In the Sheffield County Court, on Wednesday, March 26th, before T. Ellison, Esq., judge, an action was brought by Martin Carr, Change-alley, architect, against Dr. Geo. Harrison, St. James'-row, to recover £12 for work done. The plaintiff's case was that he drew up plans and specifications for two dwelling-houses at Ranmoor, Sheffield, by the defendant's instructions. When tenders were sent in for the buildings the cost was considerably more than the defendant anticipated, he abandoned his purpose and subsequently sold the land. The defendant, who is a retired chemist, first intended to build a detached dwelling to reside in, for which the plaintiff made him preliminary sketches and gave an approximate estimate; this plan was abandoned, and another plan made for two semi-detached houses, when another estimate was given, but the plans were rejected on account of cost. The plaintiff then prepared sketches of less expensive houses, but were not accepted by the defendant, as he considered something better should be built. A final set of plans were made and approved, and instructions given to prepare specifications and quantities and advertise for tenders. The lowest tender being £1,200, on which the claim was based, 2½ per cent. being charged for plans and specifications, and 1 per cent. for quantities. For the defence it was submitted that £5 which had been paid to the plaintiff was sufficient compensation, the cost of the buildings being several hundred pounds more than the defendant intended to pay. The building rules of the estate were produced to prove that the price of a pair of houses on that particular part should be of the value of £300. His honour, in summing up, said that as he (the judge) understood it all such rules fixed a minimum price only. The defendant, who was a retired gentleman, wished to include a greenhouse, in addition to a good library, &c., and could not expect to have these things provided for the amount stated in the defence. Judgment for the plaintiff for the sum claimed with costs.

BAD MORTAR.—At the Worship-street Police-court, before Mr. Busby, on March 27th, 1879, Mr. Henry Shipp was summoned by Mr. C. A. Gould, the District Surveyor for East Hackney (South) and North Bow, for erecting the enclosing walls of ten dwelling-houses in the Morier-road, Bow, with improper mortar. Mr. Gould conducted his own case; Mr. Shipp was represented by a solicitor. The solicitor for the defendant made an objection to the wording of the summons, that it was contrary to the Act, and that no offence was committed. Mr. Busby overruled the objection and amended the summons to the wording of the Act, "without the same being properly bonded and solidly put together with mortar." Mr. Gould produced specimens of the material used as mortar, and explained to the magistrate that it consisted for the most part of 'dirt,' with a very small proportion of sand and lime, and that although it might dry tolerably hard it would never set, and, as an illustration, produced a specimen in a bottle of water, which, after drying hard, he had been able that morning to shake up into so much mud, a portion of the vegetable matter floating on the surface. Mr. J. M. Knight, surveyor, was called by the defendant to rebut the evidence, and spoke of the very general use of burnt ballast in some parts in lieu of sand, but on cross-examination could only point out a few specks, and one or two thin lines of red in the specimen he produced from the disputed works; and on a specimen being handed to him by Mr. Gould, said "it was very good, and, he thought, better, perhaps, than the specimens he had produced." Mr. Gould then stated that the specimen he, Mr. Knight, had just approved of was a lump of mud from the canal adjoining. Mr. Busby made an order for the works to be pulled down.

THE DUSTMAN'S QUESTION.—Queen's Bench Division. (Before the Lord Chief Justice and Mr. Justice Mellor. Collins v. the Vestry of Paddington.) This, which may hereafter be known as the "dustman's case," raised a question as to what is included in dustmen's contracts to carry away ashes, dirt, refuse, and rubbish. The plaintiff had entered into a contract with the vestry to take all the breeze, dust, cinders, ashes, dirt, offal, garbage,

filth, and refuse which should be collected and removed by them, their contractors, agents, and servants within the parish for a year, which they sold to him for the sum of 6d. a cartload, and they contracted with him that they would at their expense deliver and deposit this breeze, &c., upon a brickfield of his at Shepherd's-bush. The vestry sent carts, under charge of their men, to collect the contents of the dustbins, and it was the duty of their men to take the contents of the dustbins out of the bins, put them into carts sent by the vestry, and then take them to the brickfield. The dust heap accumulated in the brickfield would, at some time or other, be sifted in order to separate the cinder, breeze, and ashes, which are used in brick making. In the course of this process the articles in question, which in the business are known as "tots," are separated, and those of the same kind being collected together are saleable, and upon a large contract like the present are of considerable value. The articles are of a very miscellaneous kind; but among the most valuable are broken white glass, bones, articles of iron, lead, and other metals, and knife handles. Throughout the period covered by the contract the dustmen employed by the vestry in collecting the contents of the bins were more or less in the habit of picking over the contents of the bins, of abstracting portions of the more valuable articles, of putting them into sacks of their own, and of selling the articles so abstracted for their own benefit. This process of selection was generally (though not exclusively) carried on upon the premises upon which they entered for the purpose of collecting the contents of the dustbins, and in these instances the men so acting either took the articles in question from the dustbin itself, from the baskets used for carrying the refuse from the bins to the carts, or as the refuse was in the act of being transferred from the bin to the baskets. They also took such articles from the carts themselves, when opportunity offered, and dealt with them in the same manner. The contractor at the close of the year, having paid the vestry £300, brought an action to recover from the vestry a sum of £1,500, the alleged value of these "tots" during the same period, his case being that they were withheld from him by the dustmen of the vestry, and that the vestry were responsible to him for the value. The vestry denied any such liability, and the action came on to be tried before Baron Pollock in November last year, when it was referred to the arbitration of Mr. Wills, Q.C., who stated a "case" to the effect above stated for the opinion of the Court, the question put being "whether the contractor is entitled to damages for the abstraction of the 'tots' by the dustmen in the circumstances stated." After some discussion, the learned judges consulted together for some time, and then proceeded to pronounce judgment in favour of the vestry.

THE ARTISANS' DWELLINGS COMPANY AND THEIR CONTRACTS.—FRANKENBERG v. THE ARTISANS', LABOURERS', AND GENERAL DWELLINGS COMPANY (LIMITED).—This case, tried last week in the Queen's Bench Division, before Mr. Justice Field and a special jury, was an action to recover a large sum of money for goods sold and delivered. The defendants admitted that the goods were supplied, but contended that they were not ordered by the proper officers, that the prices were unfair and unreasonable, that the contracts were entered into in fraud and collusion, and the defendants sought to recover back the money overpaid. Plaintiff who is a foreigner, had been established in business in this country for some years in the oil and glass business, but lately in ironmongery, and he had brought this action to recover a sum exceeding £3,000 for goods supplied to the defendants. The company in question was formed in 1867, principally by a person named Swindlehurst, in connection with Mr. Evelyn Ashley and other gentlemen of position, for the purpose of erecting dwellings for the artisan class. They commenced by purchasing Shaftesbury Park Estate at Wandsworth, and Swindlehurst, who was manager, secretary, and one of the directors of the company, made contracts with a variety of persons, and amongst others with the plaintiff for glass, oils, and paint, and subsequently for ironmongery and plumbing. The defence was, he understood to be, that the prices charged were so excessive that either there must have been fraud committed by the plaintiff's bribing Swindlehurst or having allowed him to share the profits. So far from either charge being true, nothing had passed between the plaintiff and Swindlehurst in the shape of bribery but the present of a goose (laughter) at Christmas and a dinner service on the occasion of a marriage in Swindlehurst's family. The oils, paint, and glass were supplied at the market prices, so was the ironmongery, with the exception of a few articles that might be picked out as being high. Mr. Justice Field said he had so far listened attentively to the statement of the learned counsel, and also he had looked over the voluminous particulars and details on both sides. It appeared to him hopeless to try the case by a jury. If the case consisted in an ascertained and definite charge it could be done, but instead of that it was only whether this large number of items was charged at a reasonable

price. After some discussion the judge said he must exercise his power, and refer the case, under the 57th order of the rules and orders made under the Judicature Act. He therefore made an order that the case should be referred to the official referee, with power to apply to him (Mr. Justice Field) at Chambers.

Our Office Table.

THE architectural profession has lost one of its best known and most esteemed members in America in the death of Mr. R. G. Hatfield, of New York city. For many years Mr. Hatfield had been a prominent officer of the American Institute of Architecture, of which he was one of the founders, and also a member of the American Society of Civil Engineers. His contributions to scientific periodicals were many and valuable, his last, a very ingenious discussion of the origin and nature of the ancient structure known as the Old Mill at Newport, R. I., appearing in *Scribner's Monthly* on the day of his death. Mr. Hatfield was much consulted by his professional brethren in difficult undertakings. The arched iron roof of the Grand Central Railway Depot in New York city is regarded as a fine illustration of Mr. Hatfield's boldness and skill as a designer. His last public service was as Chairman of the Committee of Award in a competition of designs for model houses for working men.

THEY manage some things more quickly in France—whether better than here is another question. The Bordeaux Regatta Club took advantage of the passage of the Duke and Duchess of Connaught through their town to testify their respect for their Royal Highnesses and commissioned one of their members, M. Tristan Lacroix, an artist of some distinction, to paint a picture of the Osborne as she lay in the Roads. This picture, first thought of the preceding day, was painted in oil, completed and framed by the time their Royal Highnesses arrived and presented to them by the president.

THE people of Connecticut have an elephant on their hands in the shape of the new capitol at Hartford. The weight of the tower has proved greater than the piers designed to sustain it can withstand, and the consequence is, the veneering of granite surrounding the southern piers is splitting off in flakes near their bases, and the whole tower is in danger of being let down into the basement. It is reported that over 15 tons of type-metal have been used in trying to remedy the evil effects of hasty workmanship and engineering. The metal has been run, while in a molten state, into the joints of the granite, with the forlorn hope that it would equalise the bearing; for it appears that the shell of granite was laid dry, without cement or any other filling in the joints, and the crushing of the stone is attributed to unequal bearing.

To make shoe-pegs enough for American use consumes annually 100,000 cords of timber, and to make our lucifer matches, 300,000 cubic feet of the best pine are required every year. Lasts and boot-trees take 500,000 cords of birch, beech and maple, and the handles of tools 500,000 more. The baking of bricks consumes 2,000,000 cords of wood, or what would cover with forest about 50,000 acres of land. Telegraph poles already up represent 800,000 trees, and their annual repair consumes about 300,000 more. The ties of the railroads consume annually thirty years' growth of 75,000 acres, and to fence all the railroads would cost 45,000,000dols., with a yearly expenditure of 15,000,000dols. for repairs. These are some of the ways in which American forests are going. There are others; packing boxes, for instance, cost in 1874 12,000,000dols., while the timber used each year in making wagons and agricultural implements is valued at more than 100,000,000dols.

THE third of a course of eight lectures on the art of the Italian Renaissance was delivered on Saturday by Dr. Todhunter, in the Museum Buildings, Trinity College, Dublin. The subject was "The True Renaissance: Invasion of the Secular Element," the phase of art described being the rise of the class of painters who distinctly aimed at technical perfection, apart from, and even sometimes in direct antagonism to, higher qualities—spiritual and intellectual. Of

these artists, who strove after skill in linear perspective in drawing the human figure, in painting from the nude, and in relief produced by chiaro-scuro—perhaps the first was Pietro du Puccio, whose sculptural fresco-scenes were fully described. Paolo Macello, born in 1397, might be regarded as the second great student of scientific perspective, and he was followed by a school of men in whom the art of the Middle Renaissance culminated, men who were, however, rather complete painters than originators. In Sandro Boticelli, subjects from heathen mythology were for the first time introduced, and these were treated quite in a modern spirit. He afterwards abandoned painting and became a penitent. If Leonardo were the Faust of Italian art, Sandro was the Hamlet; all his conceptions were melancholy, strongly individual, and essentially modern in style. Two other painters of their period, Filippino Lippi and Domenico, without possessing the genius of Boticelli, excelled him as mere painters.

AN American competition with some novel features about it has not proved favourable to the development of architectural morality. The city council of St. Paul, Minn., having occasion to build a new market-house, and apparently distrusting its ability to reach a satisfactory result by the usual process of inviting a competition of designs, has hit upon the device of inviting a competition of bids for furnishing plans, specifications, and superintendence for the building. They accordingly addressed their propositions to two architects, Mr. E. P. Bassford and Mr. A. M. Radcliff, and in reply the former agreed to do the work for three per cent. on the cost, and the latter for two and one half per cent. Mr. Radcliff was accordingly appointed architect of the new market-house. The high tone of professional practice which renders such a competition as this possible may be inferred from the fact that Mr. Bassford in a card has charged his competitor with a breach of trust, having agreed with him on a price of three per cent., while Mr. Radcliff rejoins that their agreement was on four per cent. and not three per cent., "but," he adds, "knowing from past experience Mr. Bassford's custom in competing for plans with myself, I put my bid for two and one half per cent. The result shows by his bid how well he kept his word." "It is not within the province of the American Institute of Architects to establish missions," remarks the *American Architect and Building News*, "but we might hope that the trustees would find it practicable to circulate some wholesome tracts in this neighbourhood with a few to the placing of professional practice there upon a sounder footing."

AMONG the numerous and beautiful Irish works in decorated metal in the Museum of the Royal Irish Academy, the Cross of Cong holds, says the *Limerick Reporter*, a foremost place, not only for its size, but also because it is a production in which are displayed the highest qualities of decorative art. In the year 1123, according to the Irish annals, "a portion of the true cross" was presented to Turlough O'Connor, the King of Ireland, who died in 1156. On receipt of this much-prized gift, the Irish monarch had it enshrined in the metal work yet existing. From the inscriptions on this case, two in Latin and four in Irish, we learn that King Turlough O'Connor had it made, that the work was executed under the superintendence of the Bishop of Connaught, Flanagan O'Duffy, and that the maker of it was Maclisa MacBradden O'Echain. In height this relic is 36in., the width at the cross arms is 18in., and its thickness is a little more than an inch. It is composed of gold, silver, enamel, niello, and bosses of variously coloured glass. There are a great many patterns of intricate design, and the result is a composition that for beauty of invention, management of colour, and masterly execution equals, if it does not excel, any work in ornamented metal that has ever been made. At the bottom of the cross is a circular socket, but no part of the staff remains. The designer of the cross has departed from the rigid picturesque straight lines and the rectangles of his exemplar, and has produced a work in which beauty of form, variety of colour, and exquisiteness of ornamentation are united in the true poetry of art. The outline is bold and elegant, and the junctions of curves are decorated with bosses, and the entire is of the highest quality, both for artistic conception and excellent execution.

SEVERAL Cabinet Ministers and a large number

of other visitors attended the dinner of the Institution of Civil Engineers on Wednesday. The Secretary for War responded to the toast of the Army, and the First Lord of the Admiralty for the Navy. The Colonial Secretary, in his speech in reply to "Her Majesty's Ministers," while bearing testimony to the important part which the labours of Civil Engineers had played in connection with the development of our Colonies, said he sometimes fancied that in considering schemes which were promoted for the welfare of our younger colonies, sufficient regard was not paid to the small means possessed by those communities. Lord Derby responded for "The House of Lords," and Mr. Roebuck for "The Commons." Mr. Lowe proposed, "Art, Science and Literature," to which Mr. Barry, Professor Owen, and Mr. Anthony Trollope responded. The Earl of Kimberley gave "The Guests," and the Lord Chief-Justice proposed "The Health of the President."

IN order to make the character and claims of the Builders' Clerks' Benevolent Institution more widely known, a dinner was held at the Guildhall Tavern, Gresham-street, E.C., on Wednesday evening, under the chairmanship of the president, Mr. Thomas F. Rider, who had made the suggestion. The experiment proved a success; about a hundred were present, and it was agreed to make the dinner an annual festival. The president, in proposing the toast of the evening, "Success and Prosperity to the Builders' Clerks' Benevolent Institution," sketched, in humorous terms, the history of the institution, from its founding by a few gentlemen in February, 1866, to the present time, and expressed his regret that it was not more widely supported by the class sought to be benefitted. Although in the London Directory there appeared the names of 1,400 builders and those in cognate trades who, allowing half a clerk a piece, surely employed some 700 clerks, yet there were only about fifty subscribers among the latter. He invited any builder's clerk who saw any cause for complaint, anything unsuitable, or which appeared capable of improvement, either in the institution or its management, to meet the committee, who would promise either to convince him that he was wrong, or to admit their own error and try to correct it. While the institution ought to be self-supported, still it was worthy of encouragement and aid by the master builders, and by the benevolent in this vast city, the charitable metropolis of the world. The toast was received with enthusiasm. The toast of "The Architects and Surveyors" was proposed by Mr. Howard Colls, and replied to by Mr. Franklin. Mr. T. Plucknett, in responding to the toast of "Our Employers, the Builders," urged the clerks to make the institution self-supporting and still more useful, and suggested that instead of electing one of the great master builders as president they should depart from precedent, and place one of their own number in the chair. Mr. H. J. Wheatley, secretary, announced, amidst applause, a list of donations, headed by twenty guineas from the president, and amounting to £144 17s., besides several fresh subscriptions. Amongst the principal toasts and speakers were, "The Army, Navy, and Volunteers," responded to by Major Brutton, secretary to the Builders' Benevolent Institution, and by Captain Williams; "The President," proposed by Mr. Dove; "The Past Presidents," proposed and replied to by Mr. Brookes and Mr. Plucknett respectively; and "The Treasurer (Mr. H. T. Bayes) and the Committee," proposed by Mr. Hamilton, and responded to by Mr. Bayes.

IT will be noticed that the BUILDING NEWS is increased in size to-day by the addition of eight pages. This enlargement, which is permanent, has been rendered necessary by the increase in our advertisements and the consequent pressure on our space. The eight pages added have been divided equally between our readers and our advertisers, so that both will be gainers. Advertisers will notice that a redistribution of the advertisement pages has been effected, which, without interfering with the appearance of the journal or with the convenience of binding, will in future afford additional facilities for those who desire prominent positions for their announcements.

Lamplough's Pyretic Saline is refreshing, most agreeable, and the preventive of fevers, biliousness, small-pox, skin diseases, and many other spring and summer ailments. Sold by chemists throughout the world, and the Maker, 113, Holborn Hill. Use no substitute.—(ADVT.)

THE BUILDING NEWS.

LONDON, FRIDAY, APRIL 11, 1879.

THE CHELSEA EMBANKMENT.

FOR an uninterrupted view and southern aspect, few residential localities near London can compare with the Chelsea Embankment. With an extensive river frontage towards the least objectionable part of the Thames, and Battersea Park on the other bank, the occupants of the new residences built in this fashionable part will enjoy advantages to which residents in the neighbourhood further northwards are strangers. Since Mr. Norman Shaw erected that unique reproduction of a quaint old English manor, called Old Swan House, a row of stately houses, conceived in a similar spirit, has been built along the promenade, which will before long become one of the most striking in the West End. It cannot be said that monotony, either in architectural design or of colour of material, is a vice here, for the architects, who have been striving to outvie each other in producing buildings in the prevailing style, have rather launched out in the other extreme of informality and extravagance. Next to Old Swan House is a mansion designed by Mr. A. Croft, in red brick, offering a diverting contrast to Mr. Shaw's unaffected Low Dutch. It has been built by Messrs. Gillow, has a somewhat cramped look, is broken by a deep recess between projecting bay windows of different shapes and styles, which, together with the plaster ornament, dissipates the effect. The red brickwork and carved friezes over the bays are of excellent workmanship, but the cut brick gables and ornament destroy all breadth, which is the great fault of the composition. We shall shortly illustrate it. Adjoining is a red brick, double-bayed house, built for Mr. Armitage, R.A., we believe, from Mr. Shaw's design. Next to this we come to several red brick mansions, one designed by Messrs. Goldie and Child; another built by Messrs. Macey and Sons, has a large, flat bay and gabled end, but possessing few points for remark. A little further up the embankment is a clever corner treatment in a simple style, the materials being stock, with red dressings; the arched squinch at the side of house is an ingenious and not displeasing mode of obtaining a front view; after which we come to houses building by Mr. Lascelles, Messrs. McLachlan and Sons, and Messrs. Kirk and Randall. Some of them are cut up by the mixture of white and red brick introduced, with a rather spotty result. Mr. Phené Spiers is the architect of one in red brick.

Messrs. Gillow and Co.'s new houses, from the design of Mr. E. W. Godwin, illustrated and described by us, p. 264, Vol. XXXIV., and visited by the Architectural Association last Saturday, exhibit externally a quiet and more moderate style. Quaintness and Queen Anne features are not prominent, though there is a breaking up of elevation conducive to freshness rather than fidgettiness of manner. We cannot altogether bring ourselves to think there is anything gained by the recessed bay windows, nor any peculiar charm in the arching over of the angular nooks except the light and shadow obtained thereby. In confined streets the idea is a good one, but a recessed bay under ordinary circumstances is something like an advantage nullified. Externally stock and red brick have been blended, and as the recessed bays are entirely of the latter material—that spottiness of effect we have complained of elsewhere has been avoided. The breaking back of the dormer gables to get a side-light has an un-

pleasant if not fidgetty appearance, and the white plastered finish is not in keeping with the lower parts. Lower down the cut eorrels to the balconies have a rather feeble look. Three houses have been built, but the corner one may be taken as an example of the others, though larger and more expensively finished. The entrance is on the return side in Tite-street, and here a recessed porch is the chief feature. The doorway forms a pedimental porch in carved red brick projecting from a recessed wall, the recess above being arched and the line of wall carried flush. The hall is wide and spacious, the staircase being returned at the bottom with a balustrade of quiet and massive design opposite the door. On the left is the library, with cant bay end, and adjoining a narrow room called a business-room, lighted by a window on the slant, which, together with the canted side of bay, forms a nooked balcony. The dining-room, entered from the right of hall, is certainly too small, and has been sacrificed to a billiard-room facing and lighted from Tite-street, the two rooms communicating directly by a door. The fireplace strikes us as we enter the dining-room. The chimney-piece is designed in a massive Anglo-Classic style; the architrave jambs flanked by cut consoles, a bold cornice broken into three faces forming the mantel-shelf. The mouldings are effective and characterised by the ovolo and bolder forms of the English Renaissance; the stove, of the slow combustion kind, is set in a framework of painted tiles, with figure-subjects at the sides, and Japanese frets in the corners, and a panel representing the orb of day with birds above the firegrate. The latter has a brass front of clever Japanese design, and a black and chocolate tile hearth. There is nothing else of remark, as the woodwork, left in plain stone drab, remains to be painted. The grey tile front of fireplace in business-room, and the plain reeded brass front of grate with blower impressed with a neat Oriental zigzag, are unique. A stairs and w.c. is provided near the billiard-room, and a back passage forms a communication between it and the library. The basement is certainly gloomy, and the arrangement certainly not a model in its way. On the first floor the drawing-room is decidedly small and insufficient, and many a second-rate villa in the suburbs could boast a larger one. As on the ground-floor, the drawing-rooms are sacrificed by the large central landing and stairs. A boudoir is obtained at the side of the front drawing-room, though it would have been much better to have thrown both rooms into one. In the drawing-rooms the chimney-pieces are of a more elaborate design, and the painted tile fronts have figure subjects, the colours being blue and yellow. The windows have fixed fanlights in small squares, and casements to open below, and these lead out on to balconies. We notice the back corridor is screened from the staircase by a glazed partition in panels, but we wonder what the row of gabled niche-like projections along it are intended for. Are they for bells? A lift is provided at one corner of the dining and drawing-rooms, and its space has been turned to account in making recesses in both rooms. We must say we dislike the framing of the doors with centre oblong panels, a favourite conceit with the Queen Anne revivalists. The steps to the front entrance are exceedingly awkward; the treads are narrow enough and the risers steep enough to compare with the flights of many two-storied tenements. Entering one of the other houses which are less in depth, the area of plot measuring about 112ft. by 30ft., we find it contains a spacious hall with tessellated pavement, a front library 17ft. 4in. by 17ft., and a dining-room behind, including recess, 23ft. by 17ft. The vestibule is 10ft. square, and is separated from the inner hall by an arch abutting against a square

pilaster which rises from the newel of staircase, a short flight commencing opposite the library door. A lift and serving lobby are provided with back stairs in the rear at the end of dining-room. Upstairs the drawing-rooms, front and back, communicate by folding doors, making an apartment the whole depth of house, 42ft. by 17ft. There is a small front boudoir. On the second floor there are two bedrooms, a dressing-room, and bath-room fitted with hot and cold water, a lift, and w.c. There are three bedrooms on the next floor, and three servants' rooms in the roof. In the internal fittings we notice similar stoves and chimney-pieces, though no decorative finishings. The lease of these houses is for a term of eighty-five years at a ground rent of £90, convertible into freehold, and the price £9,000, the corner house being £12,000.

In Tite-street several new houses and studios have been built, or are in progress, that deserve mention. One of these nearly finished, for Mr. A. Stuart Wortley, from the designs of Mr. E. W. Godwin, we have inspected. It forms the corner house, one front of which faces the side of the corner mansion of Messrs. Gillow described above. There is something to be said for the piquancy and quaintness of this artist's residence. We miss that fussiness and fidgetty love of cut gables and carved brickwork and strips of pilasters which some architects love so much; the fronts are plain and quiet, of stock brick relieved by red facings, a bright red tile roof of Mansard form crowning the building. There is nothing in it in common with Mr. Whistler's house, standing on the opposite side of the road, which has given rise to so much adverse and amusing criticism. It is a plain Old English type of house, with mullioned casements, and 17th century detail. There are two entrance staircases, as the house is to be inhabited by two bachelor artists, but the internal arrangements make really but one house. The staircases form external semi-octagonal tower-like projections, and the canted bay windows carried up at the corner make a picturesque grouping, though a little curious. One peculiarity is a balcony thrown across the angle of bay above entrance. The lower rooms are small and unpretentious, rather low, the windows mullioned with casements of small squares, and the cornices and mouldings simple and effective. The stairs have pleasing turned balusters, solid-looking newels, and well-moulded handrails. The chimney-pieces are of the Queen Anne type, with effective "thumb mouldings," and have slow combustion stoves, with a cast Japanese pattern blower. Upstairs there is a drawing-room and private bedroom *en suite*, 41ft. long, with folding doors of several leaves between the two, which will fold into large boxed jambs. This is certainly a rather clumsy way, as the boxed architraves project considerably into the rooms, and sliding doors could have been easily formed. But sliding doors are inartistie things! The arched recessed fireplace is a pleasing feature in this room, and the details of oak chimney-piece and brass dog-grate exceedingly simple and nice. A genuine piece of carving is introduced into a panel over the head of the folding doorway. We also notice the bath is simply recessed in one of the bedrooms. As in Mr. Whistler's and Mr. Frank Miles's house, the studios (there being two) are in the roof, which is constructed with two slopes, the lower or steeper portion being pierced for openings, and ceiled at the junction in the manner described by the architect in a recent paper read by him at the Association (see our report, March 8th). These studios make lofty, well-lighted rooms, about 40 by 20ft.; the walls and ceilings (which follow the rafters) are simply whitened, and in one of the studios we notice a large, German porcelain stove, which is found very economical

as a heating agent. There is a bay window at end, and two lofty window casements at side, running into roof in one of the studios. The other is lighted from ends. At one side is an overhanging passage, with a long, narrow trap-door in the floor of it for raising large pictures and canvases. Everything is of the plainest description, and we believe the woodwork will be painted white, or very slightly relieved. The "White House" (Mr. Whistler's), on the opposite side of the road, is of an extraordinary character—certainly less pleasing. Architecturally, we cannot place it in any of the usual categories; there is decided evidence in the mouldings to the pediment of doorway of refined taste, and a semi-Greek feeling breathes in the delicately-cut members and incised window-heads which enrich the plain white brick and stone surface of an extremely severe and monumental type of building; though for anything beyond this, either artistically or architecturally, we cannot speak in praise. Another house and studio is building at the other end of Tite-street, but its unfinished state does not admit of our saying anything of it. Stock and red brick, and tile roof in two slopes, are characteristic, though we must not forget to mention a deep-red brick parapet of extremely archaic character; a feature we notice, also, both in Mr. Stuart Wortley's and Mr. Whistler's houses.

ARCHITECTURAL DIAGRAMS.

IT is an easy matter for the student or the learner to turn to a score of excellent manuals, in which he may find an endless store of useful and practical hints upon drawing materials, and the management and execution of designs and drawings of every kind. With so much information thus readily obtainable upon the technical details of his art, the scarcity and difficulty in obtaining correct and reliable data, to guide him in the preparation of diagrams for the class-room, the committee, or the lecture hall, is all the more marked, and it is probably owing to the absence of all information upon this subject that so many diagrams upon which a vast amount of time and trouble has been expended prove very unsatisfactory for the purpose for which they were made, and that the illustrations which appeared admirable in the drawing office are so often next to useless in the lecture theatre. It may be urged that the making of diagrams seldom falls to the share of the architect; that it is no part of his professional work, and that by a few well-directed inquiries he can soon learn all that is necessary upon the subject. To the first of these objections, we can only say that cases constantly happen where drawings which can be shown simultaneously to a large number of people, are required: in law-courts, for instance, we too frequently find in disputed questions of light and air, boundaries, encroachments, and a score of other subjects, which will occur to our readers, that small-scale drawings are produced by counsel and witnesses and handed round, which very inadequately convey what is meant to the unprofessional observer. Whereas a good clear diagram hung upon the wall of the court with reference letters, could be explained intelligibly to all at once, and would clear up a host of difficulties and misunderstandings. The architectural lecturer ought, one would think, to know what is required in the way of diagrams, and would provide himself with suitable illustrations; but, strange to say, while the diagrams of the civil engineers are, as a rule, all that could be wished in works of this kind, those of the architect are generally small, confused, and unsuited for the purpose. It is only when he is led to inquire into what is best that he will find how difficult it is, as we have already pointed out, to find any rules upon the subject; and in the hope of

assisting him therein, we have brought together a few practical hints for his guidance. Firstly, concerning the material to be used, the principal rule is, if possible, to avoid paper of every kind. Cases may, perhaps, arise where paper can scarcely be dispensed with; and for such works the best material is the continuous cartridge lined with calico. By far the best substance, however, to draw on is what is known as "blind union," a strong, glazed calico specially manufactured for roller-blinds. This fabric can be had in unlimited length and of almost any width up to 3 yards, and has a pleasant and smooth surface to draw on. It also takes the colour well, and owing to its freedom from creases and folds, it possesses many advantages over other kinds of calico. It is usually sold on rollers, and care should be taken to keep it rolled, for when once folded it is impossible to remove the marks. For smaller diagrams, a cheaper variety of calico, known as "glazed lining," may be employed. This can be had in a great number of tints, and the black glazed lining is often used for engineering diagrams, the outlines in this case being, of course, in white. In using the calico, it should be tacked down on a flat table, but not stretched, and, except in the case of large washes of colour, no trouble will be experienced from shrinkage. When it becomes necessary to cover large surfaces with colour, it is generally better for diagram work to resort to rough cross-hatching. At a distance of 25 to 30 feet no difference is perceptible between a surface hatched over and one tinted. It is as well to remember that unglazed calicoes, as, for instance, "sheeting" and "twills," are more difficult to draw on, do not take the colour nearly so well as those which are glazed, and are liable to let the colour through them. In drawing the outlines of the work a soft pencil should be used and any marks made in error should be left as they are, and not erased with bread or indiarubber. Any erasure spoils the surface for tinting, and pencil lines are quite invisible at the distance from the eye at which diagrams are commonly employed. When the design has been outlined the colours of brick, stone, timber, &c., should be filled in, using gum-water as the medium for mixing the washes. A small ground glass slab, with a glass rubber, such as is sold by colourmen for tempera painting, will be found the most useful appliance for preparing the colours. First drop on the necessary quantity of stiff gum-water, of the consistency sold as "liquid gum," then add the colour and rub it into a creamy paste, just thin enough to flow from the brush. As lecture diagrams are more frequently than otherwise for use by artificial light, strong bright colours should be used. Vermilion is an excellent red for brickwork, &c., but it is very costly, and a substitute known as Chinese red is much cheaper, and covers well. Medium chrome is a good bright yellow, and cobalt the best blue. For the outlines use lampblack, or the variety known as ivory black, which gives a far finer and deeper tint than Indian ink, so often employed for diagrams. Do not use a ruling pen for the lines, as a much thicker line than can be ruled is in most cases required, and a line painted with a small brush is quite even enough for the purpose. Diagram lines are seldom wanted less than one-tenth of an inch in thickness, and the shadow lines may be one-fifth of an inch thick. Any lines made in error may be covered up with flake white; where tints have to be applied, they should be put on before the black lines, as the black can easily be laid over any other colour. It is somewhat difficult to indicate the best scale to be employed, as no one rule is applicable in all cases. Diagrams of buildings for use in large rooms should not be drawn to a less scale than one inch to the

foot; we generally work to one-eighth full size for buildings of a moderate size. Block printing is best for diagram-work; the letters for titles and the principal places should not be less than 3in. high, and the small letters not less than 1½in. As a general rule, it is well to trust as much as possible to plain shaded outlines. Shadows and flat-tints are apt to confuse. The calico diagrams should be tacked to a strong lath at the top only, and allowed to hang freely against the wall. With a little care they are easily nailed up so as to hang quite flat. If they are to be used repeatedly they may be rolled round the laths used to suspend them from, and are thus kept free from creases. It is seldom necessary to use diagrams larger than one yard by 2 yards, and it is better to subdivide the work so as to employ a number of diagrams of this size rather than the cumbersome and unwieldy sheets which exceed these dimensions. We may state, in conclusion, that excellent blind-union may be purchased at the rate of about 7d. per square yard, and that the colours suitable for the purpose cost about 1d. or 2d. per oz., and are best applied with camel's-hair or sable brushes.

THE SINKING OF TUBULAR FOUNDATIONS BY COMPRESSED AIR.

ALTHOUGH the method of sinking iron cylinders for bridge foundations by the "plenum pneumatic," or compressed air process, is well understood by engineers, there are very few, we imagine, who are acquainted with the practical methods adopted. To the United States we must turn for any information of this kind, and it is satisfactory to be enabled to give some more precise details than ordinary descriptions and reports furnish. We find in the current number of the *Transactions of the American Society of Civil Engineers* a very instructive paper on the subject, by Mr. D. McN. Stauffer, C.E., member, describing the application of compressed air to South-street bridge. The plan adopted was proposed by Mr. John W. Murphy, C.E., who was also the contractor for the bridge. The latter crosses the Schuylkill river at a part 467 feet wide from the banks at low tide, with an average depth of water at low tide of 20 feet, and a range of tide of 7 and 6-10ths feet. A marshy meadow [subject to overflow bounds the river on the west. The rock or substratum of river consists of a micaceous gneiss, dipping and irregular in surface, soft and shelly on top, above which was found a deposit of hard gravel, sand, and mud, varying in depth from 24ft. to 5ft. There were three spans of iron, two 192ft., and between these a draw span of 200ft. long. Between the truss centres the widths, exclusive of footways, were 36ft. in the former and 23ft. in the latter case. The arrangement required, therefore, three piers: one a pivot-pier, its centre being 99ft. distant from the centres of the piers east and west of it. The footways were outside of the trusses. From the flow to low tide level was 42ft. Such were the conditions of the site. It now remains for us to describe the manner in which the pier-cylinders were constructed, and how they were sunk in water 50ft. deep till they reached a rocky bed. They were made up of east-iron cylinders made in sections 10ft. long, with a thickness of metal of 1½in., joined by inside flanges 2½in. wide and 1½in. thick, with bolts 1½in. diameter spaced 5in. apart from centres. The pivot-pier was composed of a central column 6ft. in diameter surrounded by eight columns, each 4ft. in diameter, arranged octagonally, the cluster having an outside diameter of 36ft. The mode of sinking was both ingenious and simple. No platform was used, but two common canal boats, each 100ft. by 17ft. wide, and drawing 4½ft. of water, were placed parallel to each other 15ft. apart, and

secured by two timber clamps, each made of three pieces 12in. by 12in., resting on the boats, and extending to their outer sides. The opening made between the clamps was adjusted to suit the diameter of the cylinder, and the clamps were drawn together and made to "hug" the cylinder between them by two heavy iron rods passing through them on each side of it, with nuts and cast-iron washers. Upon this platform of boats and clamps a four-footed derrick 50ft. high, made of 12" x 12" timber, and well braced, rested, its apex being directly over the centre of opening. Its feet were secured by strong iron straps and bolts to timbers framed into the two boats. The hoisting tackle was made of two double 12in. blocks, with a $4\frac{1}{2}$ in. rope, worked by a capstan on one of the boats. Some care was required to keep this floating platform in position—to prevent its being shifted by the tidal currents, and for this purpose four heavy anchors from the bows and sterns of the boats had to be maintained, and the cables adjusted when necessary. The compressed air machine necessary for supplying air to the workmen in the sunken cylinder consisted of two single-acting air cylinders, 9in. in diameter and 10in. stroke, with a small reservoir at the top of machine. It was a single 8-horse power "Burleigh compressor," and was placed in the hold of one of the boats. A storage reservoir in connection with it—an ordinary cylindrical steam boiler set on end, 22ft. long and 2ft. diameter—was provided, to keep always in hand, in case of accident or stoppage of engine, one half-hour's supply of compressed air, so that the workmen inside would have time to escape. The air was conveyed by a gum and canvas hose, $4\frac{1}{2}$ in. diameter, to the working column under operation. Having thus given some explanation of the apparatus, we may next describe how the cylinders were united and sunk. The position of the pier or column having been marked by points on the shore, the boats and derrick were brought over the site, and the sections to form the cylinder were one by one rolled on the clamp timbers attached to the hoisting tackle, bolted together, and then lowered between the clamps. The operation was as follows: the bottom section had no lower flange, the better to enable it to penetrate the bed of river; it was hauled up into a vertical position, lowered between the clamping timbers which formed a guide, and then held tightly by screwing the clamp-rod nuts. After being thus secured another section was hoisted, and lowered down upon No. 1. The two sections were then bolted together, a packing of lamp-wick dipped in a composition of white and red lead having been placed between the flanges. After the two sections were bolted together, the clamping rods were loosened, and this portion of cylinder was allowed to slip down between the clamps, and another section bolted on as before. The operation was repeated until the bottom of section 1 was within a short distance of the river bed, and generally five 10-foot sections were thus bolted together. Upon the upper or last bolted section the "air-lock" was attached, which was another cylinder of the same size, but before it was bolted on a cast-iron diaphragm with bolt-holes was put on top of the section last in place. This formed the floor of the air-lock. It had a centre manhole, having a valved door opening downwards with an air-tight rubber washer, and three perforations for the air-supply pipe, the water-pipe, and the equalising pipes, these being of ordinary gas-pipe 3in. diameter. If found necessary to sink the column through a considerable depth of material overlying the rock, other sections were added directly on the top of upper diaphragm and the air and water pipes lengthened. The operation of dropping the cylinder upon the river's bottom was a tedious one in some cases. As we

have seen, the clamps acted as guides, and it was only necessary to loosen the nuts to allow the column to slip down slowly, penetrating the mud as far as its weight permitted. When the column had found a bearing the rods were loosened so as to give a free play all-round cylinder for the rise and fall of tide. The next operation was to remove the water from the inside of the column. For this purpose the floor of the airlock was secured, cutting off the outer air from the working chamber below it, the stop-cock of the air-supply pipe from "compressor" was opened, and the compressed air was allowed to pass from the reservoir into the working chamber. As the air-pressure increased inside, the water was forced out from below the bottom of the cylinder until it was empty. If the cylinder became imbedded in a stiff and impervious mud the water had to be forced out through a water-pipe over the top of column. Having evacuated the iron column of the water, the working gang descended into the "airlock," the upper door was hauled up and tightly closed by an outside watchman, who gave a signal upon which the inside foreman opened the valve of the equalising-pipe by which the compressed air from the working chamber was admitted into the lock. As soon as the pressure was equalised on both sides of the lock door it was opened and the gang of two or four men, according to the size of cylinder, descended by means of a rope ladder, and commenced excavating the material found inside the column. Twenty bags of $1\frac{1}{2}$ cubic feet each were filled and hoisted into the lock per hour by light block and fall tackle suspended from the upper door. Candles were used to give light in these dark chambers, and the compressor was kept at work supplying fresh air and driving out the vitiated during the time the men were engaged. About $3\frac{1}{2}$ hours the men were employed in excavating the material, after which they ascended to the air-lock, closed the door, restored the air within to the normal atmospheric pressure, the upper door was again opened by the watchman outside, and the gang consumed the remainder of their 4-hour shift in hoisting and emptying the bags of *débris* stored in the air-lock. If the inside material was all removed to the bottom of cylinder, a fresh sink is made by allowing the compressed air to escape, and the water to fill again the working chamber. The rush of water through the bottom of cylinder loosens fresh soil, the lifting power exerted by the compressed air is exchanged for the normal weight of cylinder, which accordingly sinks a further distance into the bed of river. Sometimes the settlement is sudden, and as much as 6ft. at a time; in some cases the cylinder will strike a boulder or other obstruction, and a sudden lurch throw the column out of perpendicular. In such an emergency guys were employed to right the column. In sinking a large cylinder 7ft. 9in. inside diameter, it is obvious a considerable lifting force or upward pressure of air against the diaphragm would be created, and this had to be counter-weighted by a wood platform built low down inside the column, and loaded with stone; yet not to interfere with access to the bottom a central shaft was left 3ft. square, and the annular space filled with the rubble. The stone was afterwards used in filling up the column with masonry. Deducting the weight of the seven sections of an 8ft. column, 38,000lb. remained to represent the lifting power of the air-pressure. The pier columns having been thus driven down to their bed, they were secured to the levelled rock by cast-iron brackets with bolts into the rock, from 8 to 16 brackets being used according to the size of column. The columns were afterwards filled to the top with rubble masonry laid dry, and well grouted with hydraulic cement grout every

3ft. in depth, and the first 10ft. of masonry were laid under pressure. This height of stonework was found sufficient to seal the column against the entrance of water from below, after which the pressure was removed, the water and air-pipes removed, and the masonry filling continued in the open air. The grout employed was of one measure of the Rosendale cement to 2 of sand for the remaining portion of filling. We cannot go into other detail. The weight of the bridge was thrown entirely upon the masonry, the upper surface of which was levelled and dressed off. We may add, however, that the rate of progress in sinking the cylinders was quick, as it took 218 hours from the sinking of the larger column to the rock to laying the masonry under pressure. The effect of the compressed air on the men was injurious. Three men of dissipated habits suffered from a partial paralysis of the lower limbs, and were sent to hospital for some weeks. The hot sun shining on the smaller cylinders added to the heat of the compressed air in the confined space caused bleeding at the ears and nostrils, and short hours became necessary. Among the precautions taken, a code of signals was adopted to communicate between the men inside and those on the outside of the cylinder; a watchman was always on duty on the top of air-lock during working hours, and the code consisted of a system of taps upon the side of cylinder with a hammer. Mr. Stauffer hints the value and economy of the telephone in submarine works of this nature, thereby saving the time of messengers, and its application to such undertakings is merely a question of time.

ARCHITECTURAL MOSAIC.

IV.—MODERN MOSAIC.

THE decline of Mediæval Mosaic was due to several causes, among which may be specified—the incongruity of its sparkling and extremely picturesque glass tessellation, and its wealth of colour, with the classical severity of the revived Vitruvian style, to which we may add the want of freedom and utter conventionality of design into which the Byzantine artists and their imitators had fallen. Marble Mosaic also fell into disuse, partly from the same causes, and also from the fact that the hard porphyry and serpentine marbles became more and more costly to procure, and more expensive to work. For these reasons mosaic was almost entirely superseded by fresco painting, and the incrustation of walls with highly-polished marble slabs. The only considerable building in which the mosaic art has been practised without interruption down to the present day is St. Peter's, at Rome. But even there, as we have said, its introduction was due not so much to its selection for its own intrinsic merits, but through the discovery that frescoes would not withstand the dampness of the dome, and mosaic was chosen as the only style of art likely to endure. It was, as Ghirlandaio, the artist, said, "painting for eternity." Its introduction at St. Peter's certainly helped mosaic to retain its place as a practical, living art, but no more. It was very little practised outside Rome, and the Roman artists—of whom a school of instruction was specially founded in the seventeenth century—beyond the necessary repairs of their own cathedral, did little more than practise the minute, gem-like style of mosaic, which for artistic finish, for fine gradations of colour, and delicacy of light and shade, can hardly be distinguished from the paintings themselves of the great masters whom they copy. But these minute works, however admirable in other respects, lie outside our present subject of Architectural Mosaic, which depends for its excellence rather upon broad—nay, even coarse—effects than upon delicacy and finish.

The modern revival in this country began in the manner detailed in our first article.

But it may be questioned whether we should have gone any further in the development of mosaic than in the construction of pavements in ceramic tesserae, had it not been for the impulse which has come from abroad, and for this the greatest honour is due to Dr. Salviati, of Venice. It was he who discovered and encouraged the artist-workman, Lorenzo Radi, almost the only survivor of the old race of Venetian artists who had traditional knowledge of the secrets of "smalto"-making, which in former ages had lent such glory to St. Mark's. Dr. Salviati laboured with all the zeal of an enthusiast. He sacrificed personal interests, abandoned his own liberal profession, and unassisted, and with a very small capital, founded his establishment for the revival of the glass manufactures of Venice, among which he made glass mosaic a main feature; and under both Radi and his nephew, Giovanni Albertini, the old processes are practically revived and improved upon. The school of mosaic at Rome has not made much progress itself, but has a thriving offshoot at St. Petersburg, at the Imperial Glass Works, under the control of the Russian Government. This great mosaic establishment is more especially under the patronage of Prince Garkarin, and the superintendence of Signor Bonafede, pupil of Chevalier Barbetti, the great modern mosaicist of Rome. The are also considerable mosaic works in connection with the cathedral of St. Benedetto, at Monreale, in Sicily. France nor Germany, so far as we can ascertain, have any native manufactures of mosaic. The mosaic medallions in the New Opera House at Paris were the work of Salviati, and the latest mosaics at Berlin, of which we have any account, were also by him. They were colossal figures, intended for exterior decoration, and excited great attention at the Vienna Exhibition. An attempt was made to establish a school of mosaic at Paris in the year X. of the Republic, also to introduce mosaic work as an employment for the deaf and dumb, but both were doomed to failure. In England, we are glad to say, we are not entirely dependent upon a foreigner, although many of our greatest mosaic works are by Dr. Salviati. Mr. Rust claims to have been the first English manufacturer who undertook the preparation of the "smalto," under a patented invention of his own, of which the following is his description, and which it will be interesting to compare with the ancient methods previously described:—

Glass (old, broken, or waste by preference, for cheapness) is first pounded or reduced to powder, or it may be melted in a crucible or furnace. With this is mixed as much sand as it will take up, together with colouring matters or pigments; these materials are then melted together, and the articles so produced, whether slabs or blocks, or decorative designs, or other objects, may then be polished by means of iron and wooden polishing wheels as used for polishing glass. The proportions of sand and glass used by preference are: glass, 1 cwt.; sand, 30 to 40 lbs.; but the proportions may vary from 20 per cent. of sand to equal parts of sand and glass; the quantity of sand used for pavement work, or for the higher parts of buildings, or for a *recedos*, should be greater than that used for decorative objects or parts of a building nearer the eye of the spectator. The sand mixed with glass and colouring matters gives an appearance of stone, the materials being in the furnace or crucible for about six hours; but if they are left for a longer time the spots or specks giving the mottled appearance of stone would disappear, and the material resulting would be uniform in colour. Barytes, strontian, magnesia, or other earthy matter may also be used instead of or in conjunction with sand; but sand is the cheapest, and preferable to the others.

In order to colour the material a small quantity of oxide of cobalt will give the pattern and colour of lapis-lazuli; oxide of copper will give brown, dull red, green, or iron colour, according to the quantity used; oxide of iron will give a yellow or amber colour, and oxide of manganese a purple and grey or brown; the light and dark green materials mixed in the crucible will produce the shades for malachite, and the lapis-lazuli will be produced by a similar mixture of light and dark blue. Imitations of marbles with serpentine colours or veins may be produced by mixing the colours in the crucible or pot at one time, and moulding them into shapes and forms; other colours or mixtures may be produced by the use of suitable oxides or pigments.

The first artistic work executed with the above materials was the picture of "Palissy the Potter," exhibited at South Kensington, in 1867. Since that time they have been used for the decorations of Manchester Town Hall, for some of the pavements and the grand staircase at South Kensington, and at the present moment the very extensive mosaic decorations in the chapel of Sandhurst College for the Government, are being executed also in the same material. A fine opportunity now exists for comparison of this and other purely English work with that of Salviati at South Kensington, where the different specimens are placed side by side. Among Rust's works now to be seen there, may be mentioned a head of Daniel the Prophet, intended for one of the spandrels of the dome of St. Paul's, where we may hope one day to see it side by side with the splendid works of Salviati already there. In Messrs. Rust's atelier, at Lambeth, may also be seen a mosaic of moderate size, representing the Gospel story of the tribute money, and which at a very little distance might easily be mistaken for an oil painting. This minute-work however, we may again say, is a little outside the legitimate field of architectural mosaic. English glass mosaics by other eminent workers may also be seen and compared at South Kensington.

We now propose to explain as far as possible the various technical processes at the principal modern manufactories abroad. The following account of the mode of manufacturing the "smalto," or mosaic material, at Rome, may be taken as a type of the method everywhere else. The enamel consists of glass mixed with metallic colouring matter, and is heated at the manufactory for eight days in a furnace, each colour in a separate pot. The melted enamel is taken out with an iron spoon, and poured on a polished marble, placed horizontally, and another flat marble slab is laid upon the surface of the melted enamel, so that the enamel cools into the form of a round cake of the thickness of 3-10th of an inch. To divide it into smaller pieces it is placed on a sharp steel anvil called *taghiolo*, which has the edge uppermost, and a stroke of an edged hammer is given on the upper surface of the cake, which is thus divided into long parallelopipeds or prisms, whose base is 3-10th of an inch square. These again are divided across their length by the *taghiolo* and hammer, into pieces of the length of 8-10th of an inch. The cakes are sometimes made thicker and the pieces larger.

For smaller pictures the fused enamel is drawn into long parallelopipeds or quadrangular sticks, and divided by *taghiolo* and hammer or by a file, sometimes by a copper blade and emery; sometimes polished on a horizontal wheel of lead with emery.

The beauty, softness, and great variety of colours, with the requisite degree of opacity, purity, and solidity of the mosaic material, are dependent on the quantity and quality of the mineral substances employed for colouring, and the continuance and degree of heat in which they are fused together; and if these processes be imperfect or irregular the appearance and durability of

the mosaic will be affected. If the paste be not well and carefully elaborated, or if the mineral elements be not exactly proportioned, so that either the paste is transparent or some other defect ensues, then it is utterly impossible that the enamels can properly reproduce the painting, for the colouring is uncertain, weak, and almost lost through the transparency of the materials. In this state mosaic is liable to injury from dirt, damp, smoke, and all atmospheric changes.

To produce gold and silver enamels great knowledge and experience are necessary. On a ground of thick glass or enamel, according as it is desired to render the gold enamel transparent or opaque, or to give it a warm or variegated colour, there is laid a leaf of gold or silver, which is attached chiefly by the action of fire; then a film of the purest glass is spread over it, and this may be either perfectly colourless or of any tint that may be required. When well made these three layers become one homogeneous body. But here is the difficulty: it is important that the surface of the mosaic should present no inequalities; if it be uneven the eye will catch the glitter of the glass, not the brilliancy of the metal, and the mosaic will look as if it was varnished over. To prevent all this the most extreme care is required in spreading the delicate film of gold without creasing or breaking, and also in the subsequent operations to prevent its being disturbed, torn, or crumpled. Another difficulty is to prevent the introduction of minute air-bubbles, which would sooner or later separate the glass from the metal, and further to avoid striæ in the covering glass. All these difficulties, of course, very much enhance the price of gold and silver mosaic, which is usually at least double the price of other colours.

The following description of the Russian works at St. Petersburg, being carried on exactly after the Roman model, will serve for a general idea of both Roman and Russian methods, and will serve to show very clearly why the more elegant and simple methods of Salviati and those practised in England are cheaper and preferable in every respect:—The atelier at St. Petersburg consists of one large hall, about 50ft. by 30ft., with a small gallery on brackets running round it, on which are cases of pigeon-holes for storing the *smalts*; these are arranged in the order of their colours and shades, which are said to number more than 12,000. The preparation of large pictures is carried on upon the floor of this hall, and the *smalts* are close at hand in the gallery above-mentioned. Besides this, there are other rooms on the ground-floor for preparing the wooden frames, mixing stucco, and other operations; and above are apartments in which small mosaics are made, for tables, &c., and for producing the very small tesserae used in such works. The first operation in preparing to copy a large picture in mosaic is to draw it on paper or canvas in outline; then it is divided by lines into squares the size of the tesserae, and these are coloured in with water-colours. A very strong wooden frame is then prepared, sometimes of balks, 5in. in thickness, and about 6in. or 8in. in depth, well clamped with iron at the angles. This frame is laid on a smooth stone table, and is filled with mixed plaster of Paris, which is then left to harden and dry, after which it is turned over, and the surface which was next the smooth table is found to be nearly perfect, and is rendered quite so by scraping and other operations. Upon this an outline of the picture is then drawn, and lines ruled at right angles so as to form squares corresponding with those on the cartoon, and the artist proceeds to set the tesserae. In order to do this he begins to cut out the stucco within the outlines of the drawing, one square at a time, sufficiently deep to take a quantity of mastic, made of

powdered marble and oil, into which he presses the tesserae, keeping the upper surface perfectly level; in this way he works through the whole picture, which is then turned over, and laid with its face to the stone table. All the stucco is then carefully removed from the back until the rough under-surfaces of the tesserae are exposed. Roman or Portland cement is then run in so as to form a solid back to the picture, which after being cleaned is ready for removal to its destination.

The smalts or glass enamels are manufactured at the Imperial Porcelain and Glass Works, and are supplied to the mosaic factory from time to time as wanted. They are in round flat cakes, 4in. or 5in. in diameter, and $\frac{3}{16}$ in. in thickness. A small apparatus formed of six cutting wheels worked by a lathe, the wheels of malleable iron, covered with tin and coated with emery, set at equal distances on an axle, slits the cakes into strips of equal width, and these are then cut transversely or diagonally, as the artist requires, with great ease by means of a file and chisel. Smaller ones are made in the same way, but the smallest are drawn out into square rods and broken to the lengths required.

The Byzantine character of the Russian mosaics involves a great cost, from the large quantity of gold tesserae employed.

In the Salviati process the drawing is made and coloured on paper, an adhesive surface is applied to it, and then the tesserae of comparatively thin glass are laid face downwards and adhere to the paper picture. The back is then covered with mastie cement, which is pressed so as to fill in the crevices between the tesserae, and to form a solid back; the whole of the back and sides are then inclosed in a zinc case, and the whole becomes a perfectly firm plate, as compact as a slab of marble, and only $\frac{3}{16}$ in. in thickness, instead of 10in. or 12in., as in the case of the Roman and Russian mosaics, and weighing hundredweights instead of tons.

When contrasted with the costliness and ponderous weight of the Russian and Roman method of producing mosaic work, that of Dr. Salviati is as one to twenty. His grand picture of Minerva, at the entrance to the Italian Fine Arts Court at the Vienna Exhibition, attracted very much notice, and illustrated the gigantic dimensions to which his work can go. A mosaic of equal size by the older methods practised at Rome and St. Petersburg would weigh at least 20 tons, and would render special structural consideration necessary in any building on which it had to be placed, whilst it did not weigh probably more than 2 tons, and was without anxiety trusted on the walls of a temporary building.

The English methods of combining the mosaic fragments into patterns is to all intents and purposes so very similar to that of Salviati, that a description of them is unnecessary.

We next propose to treat of modern marble and ceramic mosaic work.

GOLD AND SILVERSMITHS' WORK.*

A HANDBOOK under this title has been issued by the Education Department of the South Kensington Museum. It is written by Mr. John Hungerford Pollen, M.A., the author of "Ancient and Modern Furniture," and is illustrated with several wood-cuts. Glancing over the pages of the work, we find the subject—a large one—has been treated in a popular yet thorough manner, the researches of Mr. Layard, Dr. Birch, Müller, Beckmann, Schliemann, and Mr. Roach Smith having been brought to bear upon the earlier history of the precious metals. The use of gold and silver,

besides mixed metals, by the Assyrians, has been proved by Mr. Layard and Dr. Birch, the latter of whom refers to the silver vases of the Tahai as a "remarkable tribute," and as showing great excellence in working. Again, the walls of Eebatana, 700 B.C., were silvered and gilded in the inner circuits or parapets; here it is thought a mixed metal was used. The masonry of the other walls was stained. The temple of Belus had a golden image of colossal size. This and other recorded statues of gold were, it is thought, made of wood and plated. Phidias and the Greek artists used plates, hammered and engraved. The art of chasing out lines and inlaying a kind of *niello*, or black composition, was well known, and the Greeks, like the Egyptians and other ancient nations, employed gilding largely, not only on metals such as bronze, but on wood and external masonry. In the first case gold was laid on as an amalgam with mercury, the latter being evaporated afterwards. For coating wood or stone, "gold leaf of a tolerable substance was laid on a prepared bed made of chalk, marble-dust, or other composition, with animal size admirably tempered as in modern water-gilding," and sculpture and architectural ornaments were thus enriched. Greek and Roman workmanship is amply treated; the Byzantine revival of gold and silver work, after the decay of Classic art, exhibited a vigorous kind of art; the Classic outlines and details were borrowed; but, as Mr. Pollen remarks, the compositions are heavier and less graceful. Gold was used to excess in the enrichment of the basilicas, altars, chalices, censers, and other sacred vessels, particularly in the time of Justinian. Precious stones, *niello*, and enamel form a large part of Byzantine goldsmith's work, and these kinds of decoration are described. *Cloisonné* and *champlevé* enamels are explained. The author mentions the treasure of gold and precious stones discovered recently near Toledo, in Spain, which affords evidence of the goldsmith's art in that country in the 7th century. Charlemagne was a great promoter of the art in western Europe, and his crown is engraved in Mr. Pollen's handbook. This is still preserved in Vienna. The Saxons were skilled as goldsmiths, and Mr. Roach Smith says, "in artistic merit, in style, and design," their jewels show a closer relationship to classical art than those from other parts. Pendants and necklaces, found in Saxon tombs of the 6th century, exhibit elegant design and workmanship, and the specimens in the Kensington Museum may be referred to. In Alfred's age (9th century) the art was much cultivated; but few examples of chalices, patens, or other utensils are to be seen. Irish Celtic work comprises many ornaments of unsurpassed beauty. The Bell of St. Patrick at the South Kensington Museum furnishes a good example of the plaited and interlaced patterns used, and gold plait-work and frets seem to have been common in surface decoration. The gold and silver work of the 11th and 12th centuries is well known; altar utensils—pyxes, patens, chalices, crosses, reliquaries—were undertaken by artistic Benedictines; and the abbots of Ely and St. Alban, among others, were famed as schools of goldsmiths. Architectural forms were largely copied in the ornaments. The golden altar-front from Basle Cathedral (1003-1024) is one of the engravings given to illustrate this period, and casts of candlesticks executed at Hildesheim by Bishop Bernward are to be seen at Kensington. Among those illustrated we find the elaborate Gloucester candlestick, a work of the early part of the 12th century, showing great spirit in the bands of sculptured figures, birds, and monsters; another, the *albero* of Milan, a seven-branched candlestick of exceeding elegance, made of gilt-bronze. The leaf-work and

bosses which adorn the stem, and particularly the base made up of four dragons, their tails forming volutes round the stem, are beautifully designed and wrought. Mr. Pollen observes—"Most of the reliquaries, whether large gabled-roofed chests or small movable enamelled pieces that could be put on the altar, were made with round-arched niches and colonnades, acanthus-leaf capitals, crestings, and finials in accordance with the architecture of the day. Nor were reliquaries or shrines only made in this architectural spirit. The censers curiously carry out the same type, and were crowned with towers, turrets, and pinnacles, through the windows of which the smoke escaped. A remarkable example is kept in the cathedral of Trèves." The details of ornamentation were always bold and full of invention, though the ductility of metal was kept in view. We observe engravings of chalices of the 13th, 14th, and 15th centuries, many of excellent design; but we pass on. An interesting chapter is that on the seventeenth and eighteenth centuries. It is illustrated by cuts of Flemish, Louis Quatorze, Louis Seize, and Queen Anne examples, with sufficient explanations to render the peculiarities of those styles understood. Electrotype casts of these are to be seen at Kensington. A useful chapter on "Hall Marks" concludes the book, which will be found an instructive popular handbook and an introduction to the connoisseur.

OUR COMMONPLACE COLUMN.

GIRDER (IRON).

A GIRDER may be called, for the sake of distinction, a flanged beam, in which the material most active in resistance is placed in flanges at the top and bottom, while the centre part or the web is thus reduced in substance, and merely unites the two flanges. In cast-iron girders the top flange should not be less than $\frac{1}{8}$ the area of the bottom flange. A length of 25ft. is considered a maximum for cast-iron girders, and they should never be less in depth than $\frac{1}{20}$ of the span. The loads on girders in building are generally of a uniformly distributed character, though in every case the maximum weight should be taken. The size of the girder depends on the weight to be carried and the proportion of span to depth. The most economic proportion is 12 to 1. The rule to find the strain on either flange of a wrought-iron girder, supported at ends and uniformly loaded, may be expressed in words as follows: Multiply the load in tons by the clear span in feet, and divide product by eight times the depth of girder in feet; the quotient will give the strain at centre of either flange in tons. A safe strain of 4 tons per sq. in., both in tension and compression is usually calculated, no allowance being made for loss by rivet-holes, a mode of calculation that really allows 5 tons for tension per sq. in. of net effective area, and 4 tons per sq. in. for compression, considering the effective sectional area of bottom flange (see "Beam"). For further information respecting the theory and the calculations of girders, the reader is referred to various articles in the BUILDING NEWS, Campin's "Treatise on Iron Bridges and Girders," Rankine's, Hodgkinson's, and other works. The term girder is applied to the main beam of a floor.

GLASS.

The essential constituents of glass are silica and an alkali. Glass has been defined as "an amorphous silicate," because it is capable of passing from the vitreous to the crystalline state. The origin of glass manufacture is uncertain, though it is well known that the Egyptians were acquainted with it, and there is a beautiful goblet of glass in the British Museum found among the ruins of Nineveh. Pliny tells a story that Phœnician merchants returning from Egypt to Syria with a cargo of soda (natron), when cooking on a sandy beach, rested their pots on blocks of natron, and found that glass was produced by the heat causing the alkali to form a flux for the sand. Dr. Schliemann discovered discs and beads of glass in the ruins of Mycenæ, though glass was not found at Ilum, nor is it mentioned by Homer. For historical sketches of the art of glass manufacture we refer the reader to Mr. Alex. Nesbitt's Handbook on "Glass," pub-

* Gold and Silversmiths' Work. By JOHN HUNGERFORD POLLEN, M.A. London: Chapman and Hall, Piccadilly.

lished for South Kensington Museum, recently reviewed by us; also to articles in Ure's Dict. of Arts, the "Encyclopedia Britannica," and "Chambers's Encyclopædia." "C. W." sends the following contribution on the manufacture of glass:—

Glass is made from a mixture of flint, sand, or broken glass (silica), and soda or potash (alkali), with lime, nitre, oxide of lead or manganese in varying proportions, melted in pots by exposure to the heat of a furnace. The principal varieties in use for glazing and other purposes in connection with buildings are *plate*, *crown*, and *sheet* glass. Each variety is usually divided into three or four different qualities, and further described by the weight per foot superficial, by the thickness, or by the finish of surface. *Plate* glass is made by pouring some of the melted glass on to a metal table previously heated, where it is rolled to the proper thickness. When sufficiently hard the plate is removed to the annealing oven and gradually cooled. The size and thickness of sheets procurable is practically unlimited. The usual thicknesses are $\frac{1}{8}$, $\frac{1}{4}$, $\frac{1}{2}$, and $\frac{3}{4}$; they may be obtained rough or rolled smooth, with a plain, fluted, chequered, diamond, or quarry pattern on surface, or ground and polished. *Crown* glass is obtained by blowing a small quantity of melted glass into a globular form by means of the tube or blow-pipe, it is then attached to a rod, the tube and neck of globe being cut off. The rod is held horizontally and rotated in front of a furnace. When the glass is reheated, the centrifugal motion is continued until the globe flashes out into a circular disc or table about 4 feet in diameter. The table is afterwards annealed. From the method of manufacture the thickness varies considerably even in the same table. The usual thicknesses run from 1-20th to 1-15th of an inch, weighing from 10oz. to 16oz. per foot super. *Crown* glass is sold in crates containing 18, 15, or 12 tables according to thickness, each table running from 4ft. to 4ft. 6in. in diameter; it is also supplied in slabs unflattened or flattened, with 24 or 26 in the crate.

Sheet glass is first blown in a hollow cylindrical form with closed ends, which are cut off, and the tube cut parallel to axis is placed in an oven with the cut uppermost, where the glass as it softens spreads out by its own weight. It is afterwards dressed if required and annealed. Annealing in water or in boiling oil is said to diminish the fragility of this kind of glass, especially with the latter process. When dilated by heat the oil enters into the composition, imparting a certain elasticity and toughness to the glass. Sheet glass can readily be obtained in sheets containing about 20ft. super., and up to $\frac{1}{4}$ of an inch in thickness, the usual thicknesses weighing 15oz., 21oz., 26oz., 32oz., and 36oz. per foot super. It is sold in crates of stock sizes, containing a certain number of sheets according to thickness. Sheet glass can be obtained flattened or bent to any shape or form, either colourless, polished, fluted, chequered, obscured or ground, enamelled, embossed, tinted, stained, or coloured, with combinations in figures or colours of endless variety. The colours are known as "flushed" when burnt in on the surface. Pot-metal colours are added to the glass when melted in the "pots." In 1875 M. de la Bastie succeeded in removing the brittleness of glass by suddenly plunging it into a bath of oil when the glass was at a cherry heat.

The colours employed in glass manufacture are yellow from charcoal, antimony, or silver; red from sub-oxide of iron, oxide of copper and from gold, protoxide of iron; green from protoxide of iron, oxide of copper, of chromium; blue from cobalt, also from iron; amethystine from manganese; brown from do.; orange from peroxide of iron, with chloride of silver; black from scoria of iron or charcoal.

GLASS PAINTING.

For information on this subject we refer the reader to various articles in the BUILDING NEWS: J. B. Waring's "Arts Connected with Architecture: Stained Glass, Fresco, &c., in Italy"; Warrington's "History of Stained Glass"; C. Winston's "Inquiry into the Difference of Style in Ancient Glass Paintings, especially in England"; also his *Memoirs* illustrative of the art; &c.

MODES OF COLOURING GLASS.

There are three modes in use:—(1) That in which the colour is mixed up with the molten mass, called "Pot-metal glass"; (2) that by uniting a thin layer of coloured glass with another layer, either plain or coloured, called

"flushed" or "coated" glass; (3) that in which the colours are painted on and burnt in, as in painted glass. "J. A." writes, as regards the latter:—The mode of procedure is as follows: The design having been first drawn on paper, the glass is laid thereon, and the outline traced with a coloured fusible glass. The parts intended to be yellow, orange, or red are then coated on one or both sides, according to the tint required, with a mixture composed of silver, antimony, and oxide of iron. The glass is then exposed to a red heat, in which process the tracing colour is fused and adheres permanently to the glass. The mixture of silver and antimony stains the glass, but does not melt; so that the oxide of iron, which is in the state of dry powder, may be brushed off, leaving the glass coloured, but as transparent as before.

PRINCIPLES OF GLASS PAINTING.

Certain principles, as regards design and colour, should govern glass for windows. Among these are, that the subjects should be chosen with respect to the architecture and window tracery; that the drawing should be simple in outline and conventional in treatment; that the colours should harmonise, and not be too heavy in tone; that relief or shading should be avoided, as contrary to the object of window-colouring. The earliest stained glass, such as that at Canterbury, shows lozenge, circular, and other shaped glass painted with Scriptural subjects. In the Early English period foliage, scrollwork, and diapered patterns appear; quarries were introduced in which emblems, leaves and flowers were painted. Figure-subjects, with canopied niches, succeeded in the Decorated period, and geometrical designs gave place to pictorial and natural subjects, and glass-painting ultimately fell into the error of imitating pictures, losing sight of the character of transparent colouring. (See Viollet le Duc's "Dictionnaire Raisonné.")

GLASS MOSAIC.

Several kinds of glass mosaics are in use: there is *Roman Mosaic*, composed of small pieces of enamelled glass, called *smalto*; *Venetian Mosaic* is composed of irregular pieces of all colours, the ground being gold; *Opus Grecanicum*, in which small cubes of coloured *smalto* are inserted in grooves of white marble, about half-an-inch deep, in geometrical patterns. Dr. Salviati's Venetian mosaic has been largely employed, and the process is inexpensive. Similar kinds of glass mosaic of irregular cubes are known as Stevens' Mosaic and Rust's Glass Mosaic.

GLAZING.

We refer the reader to Gwilt's, Hurst's, and other works for general information upon this trade. For fixing glass to stone mullions, a mixture of Bath-stone dust and linseed oil, made like putty, is recommended as elastic, and more waterproof than Portland cement. It withstands settlements. Saddle bars are usually placed in old windows from 8 to 9in. apart. Short intervals are to be preferred. Iron standards also are necessary in wide windows, with patterns, and even in picture windows, if they do not cut the principal figure (see Winston on "Glass Painting.") We may refer here to a new and much improved system of glazing for roofs and skylights, called Helliwell's system; for particulars, see article in BUILDING NEWS, page 543, Vol. XXXIV. See also Rendle's Patent System, both of which obviate the evils of contraction or expansion, and putty joints.

"GLORY."

The glory is the circle of light usually painted round the heads of angels, saints, &c. M. Didron, in his invaluable "Christian Iconography," gives a most detailed history of the glory, its nature, origin, and character. He says, "the term glory is employed to express the union of the nimbus (vide infra) and aureole."—C. F. W.

GLYPHS.

Glyphs (from Gr. *γλυφειν*, to hollow out) are the vertical channels with which the Doric frieze is ornamented. In the Greek Doric they are worked from the angle of the entablature, whilst in the Roman they are worked from the axis of the column. The glyphs are cut angularly, and are generally grouped in threes, and hence called triglyphs. The spaces between the channels are flat and narrow.—C. F. W.

GORGED.

A term used in heraldry to signify that the neck

of an animal, &c., is encircled by a band, coronet, &c.

GOthic ARCHITECTURE.

The term Gothic is used (in an architectural sense) synonymously with Pointed. Professor Parker says that the term was given as a reproach and contempt at a time when it was the fashion to write Latin, and applied to the Mediæval styles at the time of the Renaissance of the Pagan orders:—

"Denique nil sapiat Gothorum barbara trito
Ornamenta seculorum et monstra malorum."

The term Gothic is, however, frequently used in its broadest sense, including the Romanesque. Schlegel, in his "Principles of Gothic Architecture," to which the reader is referred, says:—"The general title of Gothic architecture, if that great national name be taken in its widest sense, for the old Christian and romantic style of the Middle Ages, from Theodoric down to the present time, is decidedly the most appropriate, and must ever be retained." In treating of English Gothic, it is more convenient to do so under the different periods to which its varied forms belong. Thus (1) the Early English, or First Pointed, 1200-1300; (2) Decorated, Second or Middle Pointed, 1300-1400; (3) Perpendicular, Third or Late Pointed, 1400-1500. It must be borne in mind, however, that the last quarter of the century is passing on towards the style of the succeeding century.

Gothic architecture is intensely ecclesiastical. To study its origin will be to study the history of religion. We must not, however, confine ourselves to merely English Gothic, but must consider also the form it assumed in France, Germany, Spain, and Italy. In this last country it never rose to its purest form. Classicism was always uppermost in Italian thought.

In its fancy Gothic architecture was a universal style, free from national characteristics. At length, however, it was moulded (so to speak) to the particular climates and requirements of the people.

In Classical architecture horizontalism, the static force, is the pervading feature; whereas in Gothic verticalism the ever-striving upwards, the dynamic force is the all-pervading idea. The Gothic is realistic or naturalistic, and hence is free, and progresses unfettered. Its forms are copied directly from nature. The capitals are clusters of foliage and flowers. The finials, corbels, crockets, brackets are in many instances direct imitations of nature, as we have already seen (FOLIAGE).

Undoubtedly Gothic architecture owes much to the monks, and it is a moot point whether the poets influenced the mediæval artists, or *vice versa*. Dante's great poem has been aptly compared to a Gothic cathedral: *Inferno*, the crypt; *Purgatorio*, capitals, corbels, &c.; *Paradiso*, the upper parts, with wall-paintings of Biblical scenes.

Speaking of Early Gothic, M. Caumont remarks: "At the beginning of the thirteenth century architecture is imprinted with a physiognomy which repels the former style; it is not, however, until the middle of the 13th century that it acquires lightness, elegance, and pleasing proportion, which give so much superiority to the First Pointed style over those of later centuries."

We may refer the reader to the works of Fergusson, Rickman, Sharpe, Paley, Scott, and Parker on English Gothic; Wilson on Scotch; Petrie and Stokes on Irish; V. le Due, Agincourt, Caumont and Gayer-Beau on French; Hittorf, Oüté, and Schnase for German; Pugin and Cotterill for Spanish Gothic architecture.

C. F. W.

VENETIAN ART.

THE fourth of a series of lectures on the "Art of Italian Renaissance," was delivered on Saturday by Dr. John Todhunter, in the New Museum Buildings, Trinity College, Dublin, the special topic being Venetian art. They had to study to-day, he said, the rise of art in a new centre, to a great extent independent of the influence of Pisa, Florence, or Siena. As early as the 11th century Venice had made her mark as a great maritime power, while in the 12th century she had become the mistress of Eastern commerce and the banker of Europe. In the 14th and 15th centuries she was in the height of her affluent prosperity, though Mr. Ruskin dates the beginning of her spiritual decline as early as 1418. The characteristics of

Venetian art are as different from those of the art of Florence or Siena as her political history is from theirs. The feverish changes not only in government but in principles and methods of government which astonish and puzzle us in the history of most other Italian cities are at least much less prominent in the history of Venice. The Florentines, like the Athenians, or the French of the Revolution, lived in a whirlpool of new ideas; their political life was a series of catastrophes and metamorphoses; the eager and subtle Florentine mind was constantly planting new ideas, as children plant slips of whatever takes their fancy in their gardens, to be grubbed up again before they have had time to germinate in the ill-prepared soil. The Venetians had something of the ponderous adhesiveness and conservatism of the English. They were practical rather than theoretic, and instead of splitting into murderous and suicidal factions, they consolidated into a homogeneous state, with an intense insight into their own material advantages, which Mr. Ruskin very aptly compares to "our own" English temper. With a distinct reference to England he further notices the strange phenomenon presented by the Venetians in their private religiousness and public want of religion—as if there ever was a State whose policy was religious, except when religion has taken the form of fanatical conquest, as the Mohammedan invasion of Europe and the Christian crusades! But, be this as it may, we find in Venetian painting something of the same homogeneity that we find in Venetian politics. The spirit of Venetian painting is in the main neither Christian nor Pagan, but simply Venetian—that is to say, imaginatively sensuous—the rich decorative art of a practical people, with a splendid sense of beauty, not much affected by hobbies of any kind—classical, anatomical, or scientific. The Venetian painters were painters for excellence, who, having obtained from Germany the art of oil painting, rapidly mastered this, and brought it to such a pitch of perfection as has never been equalled. The Venetian school was from the first a colour school; from the time when the modified Byzantine architecture was incrustated within and without with gorgeous mosaics and variegated marbles, and the city began to shine with gilded pinnacles and painted domes. There was something Oriental in the mistress of the East herself—this city, where the Byzantine, Gothic, and Italian imaginations met and mingled. The early Venetian painters carried down the Byzantine traditions to a much later period than the painters of any other of the Italian schools. They remained unaffected by the influence of Giotto until, as late as the middle of the 15th century, a new school of painters, influenced by Gentile da Fabriano, sprang up, not indeed in Venice itself, but in the neighbouring island of Murano. This Gentile da Fabriano was an Umbrian painter, and a pupil of Fra Angelico, whose art, as compared with that of his Florentine contemporaries, was of a very debased kind, outrivalling the Siennese painters in profusion of barbaric ornament, had just the qualities to captivate the Venetian mind, and to him is attributed the change of style which began with the Vivarini in Murano and Jacopo Bellini, the father of Giovanni, in Venice. Having glanced at the history of the Vivarini, the barbaric stucco ornamentation of the elder Vivarini, and the advance in colour and oil-painting by Bartolomeo, and of the works of their disciple, Crivelli, whose works are an interesting epitome of the changes of Venetian art, from the Byzantines to the Bellini, the lecturer came to speak of the two Bellini, who took the torch of art from the Vivarini and carried it through the 15th century down to the times of Giorgione and Titian. After an ample account of the lives and works of Jacopo and Giovanni Bellini, and of their most distinguished followers, Carpaccio and Cima. The school of the Bellini is of great importance in the history of painting, if, for nothing else, because even the smaller men were at least masters of oil-painting, who were perpetually trying slight innovations, perfecting the process and discovering new capacities in the art. There is probably not one of them who has not left a few pictures of such beauty that they have been attributed to one or other of the greatest men with some plausibility. At this time in Venice the secret power of that sleeping beauty whose name among men is Colour, was discovered, and everyone crowded in for a share of her kisses. The next lecture, which will be delivered on

Saturday week, the 19th inst., will be on Montegna, Sizzorelli, and the other great pioneers of the perfect Renaissance art of the 16th century.

SUBURBAN BUILDING MATERIALS.

UNDER the head of "Legal Intelligence" we gave a brief summary last week of a case heard before Mr. Bushby, at the Worship-street Police-court, on the 27th ultimo, in which Mr. Henry Shipp, a builder, was summoned by the District Surveyor for East Hackney (South) and North Bow, for using improper mortar. Upon very clear evidence of the nature of the rubbish which had been employed, the magistrate ordered the works to be pulled down. An amusing feature of the case was that the district surveyor, Mr. Gould, produced a lump of material which the builder's own witness, Mr. Knight, a surveyor, who doubtless imagined it had been procured from the work, pronounced it to be "very good, and he thought better perhaps than the specimens he had produced himself." We can imagine Mr. Knight's astonishment when Mr. Gould announced that this good mortar was "a lump of mud from the canal adjoining." The nature of the mortar introduced into too many of the "neat villas" on the outskirts of London is, however, beyond a joke, and we are glad to find that surveyors are looking sharply after the speculative "jerry-builders." At the Edmonton Petty Sessions, on the 31st ult., another builder, Mr. A. Jukes, was summoned at the instance of the Tottenham Local Board of Health for violating their 104th By-law, "inasmuch as he had begun to erect four dwelling-houses, the foundations of which did not rest upon solid ground, or upon concrete, or other solid substructure." These houses were situated in one of the new roads near Finsbury-park, a district which is just now being built over at a most prodigious rate. In fact, we were told that one estate there is being covered at the rate of a house per day. It appears from the evidence of the Tottenham surveyor, Mr. de Pape, that a trench 6in. in depth was dug and filled in with earth, stones, and improperly burnt clay. Cement was said to have been used in the proportion of 7 to 1, but it does not seem that much cement was visible in the sample produced in court. The concrete was, in fact, composed of dry, soft rubbish, and Mr. Crowne, the clerk to the Tottenham Board, who prosecuted, said "the samples that had been produced were in his opinion the strongest testimony that could be adduced in justification of the prosecution." The question of what thickness of concrete is sufficient to form a "solid substructure" came incidentally before the Bench, and Mr. de Pape, while he considered that on that particular ground (a stiff clay) 9in. of concrete in a trench 6in. deep was enough, said that, as "it was better to keep houses up than down," he should prefer as a general rule "concrete foundations to be at least 12in. deep." The builder who stated that he had built 600 houses in Barrow-in-Furness without any concrete at all, and seemed quite hurt when fault was found with him, admitted that he had disregarded the warnings of the district surveyor, and proceeded with the work in spite of the exception taken to the materials. He was fined £5 and 40s. per day for ten days, during which he had gone on in defiance, making £25, and 6s. 6d. costs. Mr. Abbiss (the chairman), in delivering sentence, said—and we feel we are justified in giving the widest possible circulation to his observations—"I hope it will go forth through the Press that we are determined, as far as we can, to put an end to the system of setting the by-laws of the Local Board at defiance, and to set our faces against the erection of a description of houses that must immediately they are built, or very shortly afterwards, become unfit for human habitation. If, after this intimation, builders will use improper materials, they must take the consequences." The magistrates seem to have shrunk from condemning the houses to be pulled down, as the builder said this course would ruin him. One of the magistrates on hearing this said:—"You talk of being ruined, but what about those who buy houses built upon such foundations?" It is this view of the case which is the saddest one; houses of the class so roughly handled by the Tottenham magistrates are being built in thousands in the north of London, and it is only very lately that fate has overtaken the miscreants who build them. We

have over and over again pointed out the risk that is run in buying houses of this type, meant only to sell. As Mr. Jukes shrewdly stated:—"If the work is passed, and the purchaser buys the house with his eyes open, that is his business;" and, in spite of all that can be said, people will buy and lease houses so bad as scarcely to be fit for human habitation. Ruskin talks of houses that "spring up in mildewed forwardness out of the leached fields about our capital," and this is a true picture of what indeed takes place. On a good clay soil the builder will erect a whole row of houses with a few loads of lime, and a large proportion of the mortar owes all its lime to the shaking out of an empty lime-bag over a heap of crumbling ballast. It is not only that the materials are bad; the way in which they are put together by a class of workmen rejected by all the better class of employers, and as many boys as can be crowded on to the job, is worse; and we only hope that all the authorities round London will be as vigilant as the Tottenham Board, and combine to stamp out a class of speculators who have had their day quite long enough.

VARIETIES OF BUILDING TIMBER AND THEIR DISTINGUISHING FEATURES.

THE varieties of timber in general use are not easily distinguished by those who have had little experience in building operations; and the constant question made in our pages as to the characteristics of different kinds of timber, show the difficulty experienced by some young architects and builders. In the newly-issued volume published by the Council on Education, "Notes on Building Construction," the information given under this head is somewhat imperfect. Thus, in reference to Dantzic timber (grown chiefly in Prussia), all the information conveyed as regards appearance is stated as follows:—"Its general appearance answers to the description given by Tredgold of the northern pine (*Pinus sylvestris*), though in colour it is rather whiter than other varieties." The "timber is strong, tough, elastic, easily worked, and durable, if well seasoned." These descriptions do not give the student the exact kind of knowledge about the appearance he requires; and, after all, to convey minute distinctions of colour, grain, and quality, is not an easy matter. A week at the workshop would, in this respect, be well spent by all students who wish to discriminate accurately: as some knowledge of quarries and masons' yards is necessary to distinguish the varieties of Bath stone. The following information may be found of service, however, and we extract it:—"The best balks of northern pine are imported from Dantzic, Memel, and Riga. Dantzic balks are from 18ft. to 45ft. long, and generally 14in. to 16in. square. The deals vary from 2in. to 5in. in thickness, and in length from 18ft. to 50ft. Major Seydon, in 'Notes on Building Trades,' observes the private marks on Dantzic are much more numerous than on Memel or Riga timber. All balks of crown quality are marked with an indented crown. Dantzic marks are lines scribed about the centre of each balk with short crossed lines. For best middling only the centre mark is used, for good middling only the two outer marks, and for common middling all those marks are made. Memel timber is very similar to Dantzic, but is considered hardly so strong. The scantlings of balks are smaller, being from 13in. to 14in. square. Riga timber is like the other varieties just described, but the annual rings are closer. It is slightly inferior to Dantzic in strength, is remarkable for its straight growth, for the small proportion of sap it contains, and for its freedom from knots. It is, however, frequently a little shaky at the centre, and is, therefore, not so fit for conversion into deals. Swedish timber somewhat resembles that from the Prussian ports, but the balks are generally tapering in form, of small size, and not of good quality. Appearance: The wood is of a yellowish-white colour, soft, clean, and straight in grain, with small knots, and very little sap; but the balks are generally shaky at the heart, and therefore unfit for conversion into deals. Mr. Laslett says, 'There is little to recommend the Swedish fir to favourable notice beyond the fact of its being cheap and suitable for the coarser purposes in carpentry.'

A peal of bells has been placed in St. Alphonsus' tower, Limerick. Mr. Murphy was the founder.

NEW BOARD SCHOOLS AT WIDNES.—ANGLO-JAPANESE DINING-ROOM BUFFET.—ROUND AND GREEN'S BANK, COLCHESTER.—DETAILS NEW PREMISES OF ART UNION OF LONDON.

OUR LITHOGRAPHIC ILLUSTRATIONS.

WIDNES SCHOOL BOARD, SIXM'S CROSS SCHOOL.

This building, opened in November last, is one of a series erected for the School Board from designs by Messrs. F. and G. Holme, of Liverpool, architects to the board. The accommodation provided is for 800 children, and the buildings throughout are fitted with every modern requirement. The infant school, school of cookery, and keeper's house form a separate building in Milton-road. The fronts are of grey brick relieved by dressings, strings, arches, &c., of red Ruabon brick, and stone bands, copings, &c., are from Appleton quarries. The bell turret is roofed with oak shingles, the other roofs being of slate arranged in bands with Cooper's ridges, and lead finials. The interior woodwork is of pitch-pine stained and varnished. The heating is by hot-water pipes in the main building, and in the infant school by Shillito and Shorland's patent Manchester school grate. All the rooms are carefully ventilated. The cost has been about £9,000, and the work has been executed by Messrs. Carlile & Co., builders, of Widnes.

THE "BUILDING NEWS" DESIGNING CLUB—DINING-ROOM BUFFET.

CONTINUING our series of drawings by members of the BUILDING NEWS Designing Club, we have given to-day the two best designs for a dining-room buffet. The selected design is by "Motto J.," and "J'Espère" is the author of that placed second. Each design has notes upon it which will be found to describe the author's intentions in either case.

MESSRS. ROUND AND GREEN'S NEW BANK, COLCHESTER.

THE view of this bank, representing the front elevation on the High-street, has been designed in the Fifteenth-Century manner. Internally, it comprises on the first-floor the bank offices, including the partners' and manager's rooms, &c. In the basement a very complete arrangement of fire and burglar-proof chambers, book-room, &c., and on the other floors the manager's residence. The frontage is rather confined, being only 31ft. in length, the height to top of balustrading being 33ft. The front, as shown, will be built entirely in Westwood stone. In the carving will be represented Capital and Labour,

Avarice and Prodigality; in the minor portions the Hare and Tortoise, and other of Æsop's fables, relating more or less directly to the acquisition of wealth or the reverse. Over the manager's entrance the finial will personify Cerberus, while under in the lintel will be carved "Cave Canem," and a chained dog. In the centre panel of the oriel the arms of the erectors and their crest, while in the dormers the dates of the present erection and of the original establishment will be clearly shown. The architect is Mr. Ernest C. Lee, of Bedford-row.

CARVINGS, ART UNION OF LONDON, NEW PREMISES, 112, STRAND.

WE have already* published the general drawings and details of the new premises now in course of completion in the Strand for the Art Union for London. To-day we give some enlarged drawings of the carving to the panels of the pilasters on either side of the windows of the first floor, or principal stage of the Strand façade. By reference to the general elevation, or to the detail of this part of the front published in the BUILDING NEWS for March 14, the relative positions of the portions given to-day will at once be seen. Each pilaster is divided into three parts by two circular panels containing the portraits of well-known architects, artists, and sculptors. The drawings which accompany this description show the upper and the lower parts of the four panels, with the names of the eminent artists represented. The centre or intermediate panels will be given in an early number, as the proportions of our pages prevented the publication of the panels *in situ*. The work has been beautifully executed by Messrs. Mabey, of Princes-mews, Westminster; and Prof. E. M. Barry, R.A., is the architect of the building.

THE IPSWICH PUBLIC HALL AND CORN EXCHANGE COMPETITION.

THE *Suffolk Chronicle* describes the leading characteristics of the plans sent in for the alteration of the Public Hall, Ipswich, so as to render it suitable for use as a Corn Exchange. The competition, as we announced last week, was decided on the 2nd inst., when the Ipswich Town Council awarded the premium of 50 guineas to "Tria Juncta in Uno," who proved to be Mr. Horace Cheston, of Great Winchester-buildings, London. Competitors were asked to give an opinion as to the practicability of the suggestion, and each of the seven authors of designs declared that the alteration was feasible,—the only reply that could be expected from a competitor for the arrangement and supervision of the undertaking. The Public Hall, it may be remarked, was built about eight years since, and lies north and south, the chief entrance being at the north end, in Westgate-street. At this extremity there is a balcony, with gallery above, the orchestral stage being placed at the south end. The hall itself is 98 feet in length by 50 feet wide, and communicates at rear with a saloon and other rooms.

Mr. Horace Cheston's premiated plans propose to lengthen the present public hall to the southward (the rear), making it 150 feet in length, and securing an area of 7,650 feet super. This would necessitate the removal of the present saloon, also the acquirement of a triangular strip of land. At the back of the stage, at the south end of the enlarged hall, is provided a "crush" room, with cloak room, &c., and above it a saloon similar to that now existing. The lighting is provided for by filling in the present domes with flattened lights, and constructing a clear glass roof above. Balance lifts are shown for sinking the stands into the basement when not needed. The estimated cost is £3,400.

"Utility and Economy," by Mr. William Eade, of Ipswich, shows a second hall to south of present hall, divided from it by revolving shutters. This would give dimensions of 98 feet by 50 feet (the present building) besides a small hall 56 feet 6 inches by 52 feet, and a total area of 7,700 feet super. For the present platform a sliding one would be substituted, and the gallery would be removed, and a curved and glazed roof erected at the north end. The new small hall would be lighted by an arched roof of glass, supported on iron pillars. The estimated cost is £4,500.

In the plans of "Bona Fides" (Mr. Brightwen Binyon, Ipswich), a proposal is made to widen the present hall on the west side by 6ft. 6in. by piercing arches between the pilasters, and also on the east side if possible. It is also proposed to lengthen the hall so as to make it 63ft. by 137ft., and affording, after deductions for stage, &c., floor space of 7,303 sq. ft. For the present roof is substituted a glass curved roof springing from ornamental ribs, and also to enlarge the present side lights. At the back of the hall and stage is a corridor, 8ft. wide, and a saloon 30ft. wide by 48ft. is proposed to the west of this passage. The estimated cost is £5,250.

The authors of "Postulata" (Messrs. Wright and Wright, Ipswich), avoid the purchase of neighbouring property, and propose a small south hall, separated by revolving shutters, and a sinking stage, as in "Utility and Economy." The oval panels in the ceiling are to be filled in with glass, substituting a glass outer roof for the present slates. The corn exchange area afforded would be 7,833ft., and the estimated cost £4,000.

"Economy" (Mr. Henry Luff, Ipswich) proposes a hall 152ft. long by the present width, the special feature being the raising of floor 5ft., and heightening the present side-windows to a similar extent, carrying them up to the roof-plate, with an extra row of pilasters starting from the present cornice. This would avoid the difficulty as to the side-lights being high up, and in addition it is proposed to glaze the two centro bays of present ceiling, to place a glass roof above the ceiling, and to provide two large windows at the south end. The present balcony and gallery it is proposed to remove. The plan would give an area of 7,596ft., including stage, which could be utilised for market purposes by the provision of movable steps. A movable partition is suggested for reducing the hall to any required size. A saloon is proposed at the back of the stage, with retiring rooms over it. A cement floor for the hall is also proposed, and including the costs of this, "Economy's" estimate is £1,800.

"Excelsior" (Mr. Henry Elliott, Strand, London, W.C.) lengthens the hall to 140ft. by three bays. The gallery at the north end is reduced to small compass, but, as a compensation, light balconies are run for a short distance along the side of the hall from the south end. The present roof is extended over the added portion of the hall, but the upper part of roof is removed above the straining beams, and a lantern light running the entire length of the hall inserted. A saloon is proposed at the south end and above it a green-room, dressing-rooms, &c., on the same level as the stage. The estimated cost of this plan is from £5,500 to £6,000.

The remaining plan is that signed "Grosvenor" (by Messrs. Scott, Gibby and Barnard, Mark-lane, London). The lighting they propose to achieve by opening windows between the piers on each side of the hall, suggesting arrangement with adjoining owners, by glazing the centre portion of ceiling, and placing skylights on both sides. The front of the present gallery to be taken down. The present stage and orchestra to be removed, and a new stage erected, recessed into a crush-room at the back. At the back of the crush-room a supper-room is provided, seating 100 or 200 people. The area of the large hall is the same as at present, 98ft. by 50ft., the space by the present stage being all that is gained. The cost is estimated at £3,500.

South Petherton, Somersetshire, is about to be sewered in accordance with plans prepared by Mr. Martin, engineer to the Yeovil rural sanitary authority.

A statue of the late Chief Justice Whiteside, ultimately to be placed in St. Patrick's Cathedral, Dublin, is being modelled at the studio of Mr. A. Bruce Joy, in the Avenue, Fulham.

The second section of the Nottingham and District Tramways system, extending from the Market-place to Carrington and to the extremity of Forest-road, was opened for traffic on Saturday. The engineer of the line is Mr. MacNay, and the rails are Winty and Levick's patent. The stabling and offices have been constructed from the designs of Mr. Bromley, architect.

Mr. J. R. Hay, architect, was last week presented with a handsome clock as an acknowledgment of his services in connection with the erection of new Congregational Sunday schools at Castleford.

THE SILICATE PAINT COMPANY'S NEW WORKS, CHARLTON.

SITUATED on the banks of the Thames, at Charlton, near Woolwich, the Silicate Paint Company have lately erected new works which promise to develop the resources of the company. On Monday last the works were visited by several gentlemen connected with the Press, and interested in the sanitary manufacture of paint, when Mr. Thomas Griffiths, the founder of the company, conducted the party over the new factory. The buildings, comprising blocks of substantial construction, occupy a site of about an acre in extent, and have been carried out from the designs of Mr. Ernest Turner, of Regent-street, at a cost of about £25,000. Our object here, however, is to confine the attention of our readers to the processes for the production of silicate paint, first manufactured in Liverpool, and which has gradually been growing in favour as a very desirable sanitary substitute for lead paint. White-lead is a material entirely repudiated at the Silicate Paint Company's Works, an oxy-sulphide of zinc taking its place. We may say at the onset that the silicate paint is a preparation in which silica extracted from a volcanic mineral forms the basis, its advantages being chiefly the absence of all chemical action between it and the material covered as that which ensues between iron and lead, and a petrifying surface, unpenetrable either by heat or gases. The process of grinding the pigments was the first operation inspected. In a long room are to be seen several mills and edge rollers and mixers at work grinding. Various pigments, such as ochres, and other colours combined with the patent white sulphide of zinc is passed through rollers, and kneaded into a paste of putty-like consistency. We see the same preparation combined with hard gums and mixed with oil or water. The colours are combined above with oil, and pass through shoots to mixing mills. The "petrifying liquid," as it is called, is a solution of silica, and is recommended as an effectual preparation for the protection of stone, brick, plaster, or woodwork. It has the property of hardening the surface of stucco and brick, and forms a washable distemper to walls. We understand it has been largely used in colouring the funnels of steamers, for which purpose lead paint is found quite unsuited. This liquid can be thinned with water or oil. We are told that three or four coats of this solution on brick renders it impervious to moisture, though it requires to be renewed every seven or eight years. Ascending to an upper story, the visitors inspected the mixers for dry materials, and trays heated by exhaust steam for drying the same. The preparation of "Griffiths' Patent White" forms another portion of the manufacture carried on. Beginning at the roof of the factory, we see large lead-lined tanks open to the air, into which sulphuric acid and muriatic acid are blown from an air-pump below through vulcanite pipes. The zinc is thus dissolved, and the solution is conveyed by pipes into purifying tanks below. A soluble sulphide boiled by steam in large iron vats is now combined with the zinc liquor which is conveyed to other tanks, and a precipitate is ultimately obtained which is pumped into filter presses. In these the material is pressed into cakes, which are afterwards calcined in furnaces to a white heat. It is re-pressed into cakes and placed in racks in a large drying-room made to hold 70 tons. The calcining furnaces, gum-rooms, and other appliances were afterwards examined, but the most interesting part of the inspection were the tests. First, the effect of heat on ordinary lead and "Griffiths' Patent White" was tried. Slips of iron painted with both were placed in a small furnace, and after exposure to an intense heat the lead paint entirely disappeared, while the zinc paint retained its body unimpaired. Another interesting experiment was next shown, which undoubtedly proves that as a sanitary paint the sulphide of zinc has advantages over lead in the composition of paint for certain uses. Two strips painted with the ordinary lead and the patent white were subjected to the fumes of sulphuretted hydrogen under a glass receiver. After a second or two the lead paint became quite brown, and ultimately black, while the other paint exhibited the same untarnished whiteness it possessed when placed under the glass. These tests were made in the company's

laboratory. Still larger ones were shown in the yard. A large board was painted with ordinary white-lead paint on one side, and on the other a like surface was covered with Griffiths' Patent White. A jet of sulphuretted hydrogen was made to play for a few seconds first on the lead paint and afterwards on the zinc paint. Directly the hose was directed to the former it began to get yellow and brown, and had all the appearance of being scorched by a flame. Turning the jet to the other end of the board no perceptible difference of colour was made, and the experiment, notwithstanding the intolerable odour of the gas, elicited much interest among those present.

Mr. Griffiths also showed the great covering power of this paint, in contrast with pure carbonate of lead, on four boards painted black, and of equal size, each measuring 16 square ft. Exact weights of pure carbonate of lead and of three different qualities of the "Patent White" were weighed out, and oil added. A decorator then applied them to the board with the following results:—

	Per cent. covering power.
The White Lead and Oil actually used weighing	9 oz.=100
Griffiths' Patent White, marked A, actually used weighing	5½ oz.=180
Griffiths' Patent White, marked B, actually used weighing	5 oz.=189
Griffiths' Patent White, marked C, actually used weighing	4½ oz.=236

The opacity of the lead was much inferior to any of the other three samples.

There are unquestioned merits in Griffiths' Patent White to which we may here call attention. It is a pure white of great body, which, as we have seen, does not tarnish or decompose like white-lead under the action of noxious gases; it stands great heat without blistering and discolouration, and is admirably adapted for iron structures, the walls of houses and hospitals. The silicate paint is well known to our readers. It dries quickly, with a hard surface; the porous face of the material it covers is case-hardened, and the experiments quoted above clearly show that its covering-power—a point that has been somewhat disputed—is nearly double that of common carbonate of lead paint of the ordinary quality. For resisting the action of salt water it is also recommended, so that for hydraulic and maritime purposes it has decided claims. We may add that it is sent out in the usual form, and when required for use is thinned with linseed oil and turpentine, silicate dryers being added. Every variety of colour and shade is kept in stock. The "petrifying liquid" has been largely used for covering damp walls, while the enamel paint, another beautiful preparation which retains a remarkable gloss, may be mentioned as a valuable decorative and impermeable surface for dados, walls of hospitals, and other purposes for which varnish is now employed. The "petrifying" liquid and enamel paints have, we believe, been used at the Grosvenor Gallery, and for newly-plastered walls, the solution of silica being a good preparation to facilitate the mural decoration. Large quantities have been used by the Indian and Home Governments, and the company have secured a contract for a twelvemonth's supply to the Imperial German Navy.

MR. SEYMOUR HADEN ON ETCHING.—III.

THE third and last of Mr. Seymour Haden's course of lectures on Etching was delivered at the Royal Institution on Saturday afternoon, the principal topic being the Printing of Etchings. In opening, the lecturer explained the characteristics of a dry-point line, and as compared with the etched and engraved lines described last week (see p. 369). The dry-point line might be described

FIG. 1

FIG. 2

as a ploughing of a copper surface by means of a sharp instrument which roughed the outlines

without removing any portion of the metal. If the style were held vertically the resultant impression as seen in section would resemble Fig. 1; the little horns turned up on either side caught and retained the printing-ink, so that the impression of a dry-point line on the paper from the upright style had a pyramid of ink corresponding with the groove, and on either side an indented dark shadow from the horns. In no case were the edges of a line quite true, owing to the minute roughnesses on the style. But practically the style was never held vertically—there was no need for the additional labour that would be occasioned thereby—but obliquely like a pencil. This raised a jagged ridge on the left side of the groove (see Fig. 2), and the impression from plate viewed in section was that of an irregular pyramid of ink from the incision and a deep shadow on one side indented by the ridge. The effect was that of a smear or stain rather than a definite stroke, and was totally distinct from that of an engraving or an etching. It was obvious that this roughened ridge would be rapidly worn down by handling, inking, and passing through the press, and hence a dry-point plate had no durability. Rembrandt was the father of the dry-point process. No one appeared to have regarded the method likely to be useful until the time of that artist, and even he did not utilise it till he was in the height of his career. Rembrandt's artist-life might be broadly divided into three periods of about ten years each. The first ten years were passed without any knowledge of dry-point; during the second decennial he mixed up dry-point with etching, plunging his outlines and biting them in with acid, and in that way obtained a greater amount of colour than had been done before. In the last period he never troubled himself to bite in a line, but his eye became so educated and his hand so firm that by sheer force he dug out every line on the plate. Some very fine examples of Rembrandt's work were exhibited on the screen, including the "Crucifixion"—a work in intense shadow with the exception of some vertical rays of light beaming on the central cross and dimly illuminating the mount—and the "Presentation to the People." These different works represented a gigantic labour in which great force of hand, determination of character, and complete knowledge of art were equally shown. At the present time no one in France practised dry-point. In this country some years since it was revived, but with no success; no one would buy a proof; the Etching Club did not approve of the process, and thus its use fell through. The only artist who practised it was Whistler, who, like Rembrandt, had taken it up in his later years, and some fine dry-point work had been done. But Whistler's works were entirely and uniformly fragmentary, and never carried out to completion. In order to afford a better notion of the conditions and physical properties of the engraved, etched, and dry-point line, he had prepared the following tabular summary:—

MATERIALS AND ARTISTIC PROPERTIES OF ENGRAVED, ETCHED, AND DRY-POINT LINES.

1. Engraved line: as to Form depends on the instrument that produces it—i.e., V-shaped. Capacity for containing ink, exemplified by cast it gives—moderate. Colour depends on shape and volume of cast and on shadow projected by cast—grey. Durability depends on form and extent of metallic surface left to resist forces employed to act upon it (which are, inking of plate, friction of printer, action of press)—great. Sum of artistic qualities—greyness, constraint. Sum of physical properties—great durability.
2. Etched line: as to Form, determined by action and strength of mordant—an irregular sphere. Capacity for retaining ink exemplified by cast it gives—great. Colour, depending on form and volume of cast—considerable. Durability, depending on form, and amount of metal left to resist wear—small. Sum of artistic qualities—colour, accent, freedom. Physical properties—low degree of durability.
3. Dry-point line: as to Form, depending on action of style and direction of impact—flat and extended. Capacity for holding ink depending on force employed, burr raised and depth of sulcus made—great only at first. Colour, depending on cast of sulcus and extent of surface disturbed by style—rich at first, but soon becoming grey. Durability, depending on power of resistance to pressure and friction—extremely small. Sum of artistic qualities—richness of colour suggesting velvet pile, absence of freedom. Physical properties—Durability, Nil.

Recurring to the etching process, the lecturer referred to the delicacy of the etched plate, remarking that there was a distinct difference perceptible to the artist between the first and a second impression. For continuous etching on a zinc plate he used, as he mentioned last week, 2 parts of chlorate of potash to 10 of hydrochloric acid, diluting with 88 parts of water. This was an extremely weak solution; a better proportion would be 2 of chlorate of potash to 6

of hydrochloric acid, but it would cause a great ebullition, which would interfere with the view of the etcher as he worked. It so soon became saturated and exhausted itself that the mordant had to be changed about once in a quarter of an hour, but as the solution was extremely inexpensive, there was no inducement to use it too long. It should be recollected that it was neither the hydrochloric acid nor the chloride of potash which bit the zinc plate, but the chemical interchange and reaction, steps which were simultaneous. Some ebullition of gas necessarily took place during the reaction; if none were observable the artist knew the plate was not being bitten. It was evident, therefore, that the greater the ebullition the more rapidly was the etching being bitten in, and that was why he had used a strong solution when etching a plate during the previous Saturday's lecture.

Mr. Haden then proceeded to his main subject, the printing of etchings. This was more or less of an artistic character, and had always been retained in the hands of the artist. In an old etching, by Abraham Boss, on the screen representing the printing process, it was clear that the actual printer was the artist, superintending the work of an assistant. He knew of but two printers of etchings in this country at the present day, of whom Mr. Golding (who has acted during the lectures as Mr. Haden's assistant) was by far the best he had ever met with. Mr. Brooks, a nephew of the steel-plate printer, had been spoken of as a very good printer, but of his work he had no personal knowledge. As a rule, a steel-plate printer could not be trusted with an etching; he was accustomed to handle a plate roughly, to scour it with coarse muslin, and to print heavily. As an illustration of this he might mention that some time since some excellent plates by Whistler were intrusted to a steel-plate printer. The lecturer was at the pains to visit the printer's and explain the way in which they should be treated. The man professed to understand all about them, and, as the plates were in the best possible condition, satisfactory impressions were expected. The results were so bad that, supposing the plates had been worn out by handling, &c., they were sold for a mere nothing, but the purchaser found on examination that they were still capable of use. For proofs, the paper ordinarily used was common plate paper; but it was too coarse, was scored with lines, and often contained iron and plaster of Paris, which were detrimental to the plate. The finest material for printing upon was old *vergier* paper. Some specimens of this, of the kind actually used by Rembrandt, were exhibited, Mr. Haden remarking that he had picked them up sheet by sheet, quire by quire, and sometimes a ream at a time, in Holland, Belgium, and Spain. Sheets of the old French paper, used by Turner in his "*Liber Studiorum*," were also exhibited, and were described as a very good material. Rembrandt also used a very fine paper, known as Japanese. The modern paper from Japan gave a good impression, but was dry in colour, and was not very desirable, for it became cottonous with wear. It was, indeed, the fibre of a plant, and was produced by first pounding the stems with stones till they became rotten; this was reduced with water to a pulp, and spread upon stones to become the thin paper exhibited. A very good *vergier* paper was made by Watson, but its thinness was a disadvantage; he intended to order some of thicker texture to be made, and it would then be the best for the purpose. The ink used was of lampblack, tempered with sienna, umber, and sepia; the latter might be used by itself, but it was very costly. Two kinds of oil were used—strong and weak. If an etching plate appeared weak, a strong oil was used by the printer in his ink to bring it out; and if it looked strong, he employed a weak oil. The character and composition of his ink was to the printer of etchings as important a part of his art as the biting-in was to the etcher himself. Judgment was required not only in proportioning the ingredients, but in spreading just the right amount on the plate to secure a good and uniform impression. The press used was a small wooden one, with four long levers attached to the wheel, scarcely changed or improved from the one depicted on the etching by Boss previously referred to, and which was executed about A.D. 1600. A larger press than that shown (taking a sheet a little larger than a *BUILDING NEWS* page) was necessary for etchings of any considerable size, but the principles of construction were equally

simple. The table on which the plate rested was, like the framework, of wood, but he should prefer an iron bed, believing as he did that quite sufficient elasticity of pressure was secured in the blanket and wooden roller. The blankets upon the roller should be old, and required changing at every eight impressions, or the moisture they imbibed from the paper would spoil it. The proof which was the end of all this preparation was protected by a backing of stronger paper, and it should be dried by hanging across a pole or string; the best old etchings showed on the back the mark of this line. If the proofs were laid one upon the other the delicate rounded casts and pyramids of ink were flattened, and the impressions lost shadow and were blurred. When dried singly, as in the early days, the lines would actually stand out in relief upon the paper. As these suggestions were entirely new, he ought to state how he arrived at the conclusion embodied in them. He had made sections of the various kinds of lines, and had also taken casts from plates, and examined them by the aid of magnifying powers. He did not like the term "proof" on account of the mode in which it had been used, but for purposes of illustration he would, in deference to usage, divide the impressions taken from a plate into proofs and prints. There were two sorts of proofs: one was the trial impression taken from time to time by the artist, in order to ascertain the condition of the plate. Such proofs in the case of an engraving might amount to five or even ten in number, but could never reach 5,000. For etching but three or four were at the utmost required. In speaking of the enormous numbers of so-called "proofs" taken and sold under the stamp of the *Printsellers' Association*, he had had no fear of being guilty of exaggeration, but he had taken pains to ascertain what were the actual issues. Of one of these plates £45,000 worth of impressions were taken and sold as "proofs," of another from £30,000 to £40,000 worth were sold, in every case as "proofs," and in the first case, notwithstanding that £45,000 worth of proofs had been sold, the plate was examined and taken down to the press again, when several thousand pounds' worth more "proofs" were issued before the plate was considered good enough only for "prints." The first fifty or hundred proofs taken by engravers might, however, be properly considered to be of higher value than subsequent ones, all of which should be deemed simply prints. Of etchings, on the other hand, but very few could be printed, and the price of these, if etched by an artist, would increase year by year, while the engravings already referred to would never return the purchasers' shillings, or even pence, for their outlay. Mr. Golding would now print off from an etched plate by the lecturer; he would examine it, add a few touches to the plate where needed, and return it to Mr. Golding, who would print a second impression. At the third impression he should tell him that it would do, with the number of impressions that he thought the plate was capable of producing, say, twenty-five proofs, and should mark the plate with his *bon à tirer*; should it bear more than that, all subsequent impressions would be merely "prints." The etcher utterly repudiated the mark of the *Printsellers' Association*. For himself, he wrote on the trial specimens, "Artist's proof, No. 1," "Artist's proof, No. 2," and "Artist's proof, No. 3," as the case might be, and then 1, 2, 3, up to the number to which he had put his *bon à tirer*. Thus, the number written by the etcher represented the actual number of the impression in the series, and this etchers considered a better guarantee than the *Association* stamp. One of the absurd regulations of the *Printsellers' Association* was, that the artist was required to state beforehand how many impressions of the plate he intended to issue. This, in the case of an etching, was practically impossible, for all depended on the character of the plate. If it were a soft one, the number of good impressions might not exceed eight or ten; but if it happened to be hard, it might reach a hundred. In the case of a dry-point, the durability of a plate was still more uncertain. What, it might be asked, was a "state" as applied to an etching? After a few impressions had been taken from a plate, some corrections might be made by the artist, and the printing was arrested for this purpose. Those printed prior to this alteration were therefore known as the first state of the plate. Some artists added a few scratches to the plate at each working of the press, and thus multiplied states, to the confusion of the cata-

loguer. A recent catalogue of Rembrandt's works had for the last two years been busy in enumerating such states, and, moreover, being of a busy and inquiring turn of mind, had copied all the lecturer's original observations and incorporated them into it. At this stage of the lecture Mr. Golding printed a trial proof from one of the zinc plates etched by Mr. Haden in the room on the preceding Saturday. Mr. Haden added a few lines and touches, and a second artist's proof was pulled off. Mr. Haden continued—If I now write my *bon à tirer* upon the plate, the number indicated will be well and honestly printed. In England printers never steal proofs, but in France they never neglect the opportunity of doing so. A friend of mine was in an auction room in Paris some time since, when one of my miserable etchings came up for sale. My friend knew that no more than twelve impressions were supposed to have been struck off, and he also knew what had become of them, and that this could not be one. He therefore gave twelve guineas for it at the auction, and when he had bought it he examined it in the room, and deliberately tore it in halves, and said to the astonished company, "I have received no orders for this, but I have reason to know this to be a spurious impression, and am perfectly sure that Mr. Seymour Haden will repay me the money." The people at the auction were still very much amazed, but my friend's conduct left a very good effect. The process known as "*acierage*" consists in covering, by means of galvanic action, the soft copper plate by a hard coating of steel, for the purpose of enabling the printer to take off a great number of impressions. This seemed likely to give a new power to the etcher; but a grave practical difficulty to the process is that the ink quits the plate too easily. The result is a dry and miserable impression, so that the etcher does not care for it. There is, indeed, no reason for the adoption of any such process of multiplication of copies. Certainly, the etcher has no object in publishing many impressions, and at the present time there is no such demand. If there are fifty in the whole country who care for an etching, there certainly are not fifty-one. However, *acierage* is extremely useful for coating the plate before being handled, for many plates are literally worn out before a good impression has been taken, and the steel face can be washed off by acid before the plate is printed from in the ordinary way. Such a regulation as that of the *Printsellers' Association*, which requires the number of impressions to be declared, would have been fatal to the occasional finding of etchings by the old masters, had it been in force in their day. In that case I should never have been able to secure the beautiful little etching by Rembrandt (shown on the screen) which turned up the other day, and which cost me at auction £74. The limitation caused by this *Association* has the effect of transferring property in an etching or engraving from the artist into the hands of the trade. Let us suppose that an artist published a work illustrated by, say, five-and-twenty etchings, and that 150 copies of that work are printed, and these are speedily sold at the published price—suppose we call it 12 guineas. In less than ten years the value of that work has risen to 25 guineas, and it has passed altogether out of the hands of the artist into those of the trade, who destroy the letter-press and sell the etchings in detail for 63 guineas, and in a very short time there won't be a copy of the book I refer to left. Some time since I executed an etching and gave it to one of the largest printsellers to publish. After a very short time I found that its sale mysteriously stopped, and this continued for more than a year. The publisher had, I presume, received a threatening notice from the *Association* that if he continued to sell it he would be expelled, and a note was sent throughout the kingdom. In a very short time the impressions must pass into the hands of the trade, and the artist will never derive any advantage from his etching. We have now brought our little course of lectures to a close. We have endeavoured to look at the subject theoretically and practically. We have entered into all details, have shown the advantages of etching, and its history, and have endeavoured to point out fearlessly the obstacles which hinder its revival. Art has for some years past been raised to a false level. The prices demanded by artists have been out of all proportion to the earnings of other professional men. When we hear of £2,000 being given for a por-

trait we ask why should not the doctor have £4,000 for curing a fever, £10,000 for a case of pleurisy, and £60,000 for saving life? What art can flourish at such a rate as that? If all this is so wrong, time is it that, by some unmistakable manifestation, it should be shown. Such manifestations of public opinion are being shown. It is becoming apparent that the high pressure of the last fifteen years cannot be kept up, and that the public are getting tired of "Stags at Bay," "Squirrels Cracking Nuts," and lackadaisical young ladies. I trust that this is the beginning of a change for the better in public opinion.

ART AND FREEDOM.

MR. AUBERON HERBERT, who presided at the annual meeting of the Southampton School of Art, in the course of his address remarked that it seemed as if it was impossible for a nation in a condition of servitude to have a keen perception and enjoyment of what was beautiful, or to have the power of expressing it. What, he asked, was the great moment of Greek art? It exactly corresponded to the moment of highest national greatness. The moment in which those beautiful sculptures were made in Athens, and the city was made glorious by her buildings, was the moment also of her great generals, poets, and statesmen; it was the moment of her richest and fullest national life, when the nation had just successfully fought to be free, and was exulting in her hard-won freedom. It was so also in the history of Rome, although there, as it happened, the moment of successful art was not exactly contemporaneous with that of national greatness, but followed close upon it. Nor is this unnatural. The seed had been sown, though the fruit was delayed in ripening. Passing on to a great period in the history of Europe, too, after that long sleep which they spoke of generally as the Dark Ages, when at last the country seemed to awake, and light broke in upon minds which had slumbered so long, it was soon after the year 1000 that there came to us that great and rich development of artistic power, which re-created the existence of architecture. Some 400 or 500 years afterwards, when this great wave which had touched the mind of Europe seemed to have nearly worn out, in the period known as the Renaissance, there was another wonderful outburst of poetry, literature, and art—in architecture, sculpture, and painting. Where, at that time, did they find the homes of this power? In the free cities of Italy. There were certain cities in Italy which beyond all others had preserved their individuality, life, and freedom, each like a separate thread running through the history of Europe. They would find that it was to Florence and Venice, they owed the greatest debt. Now what was the lesson which he wished them to draw from this? It was, first of all, that all who cared for art, who would enjoy the pleasure which it could afford, and who desired to see the art of this country carried higher and higher, must remember that art never can live and flourish unless it grows in a free soil, unless the awakened intelligence of a people is surrounding it and supplying it with nourishment. They must require of politicians, of those who governed them, and of all those who had charge of the fortunes of this nation, that they should watch very carefully over English liberties, so that there may ever be the right soil in which this tender and delicate plant of theirs was to grow. And he thought it not only depended—important as that was—upon what they called national freedom. "I now come," continued the speaker, "to another kind of freedom, which no statesman or public man can give you, but which each of you must win for him or herself. I mean the freedom of the inner life, that freedom of the mind which makes a man independent of the world outside him, of its caprices, its fashions, its tyrannies, which lets him see with his own eyes and judge with his own judgment. It is an old cry, that the world is too much with us; that it forces us to be of itself; that it hinders the growth of our own nature, and the fashioning of our own instincts. I say, then, let us strive to be free in ourselves—let us strive not to be caught in the current that is round us, and carried we know not whither; but let us strive to keep unimpaired our allegiance to that tribunal which is within ourselves. Let it be our own perception, our own reason, our own judgment, our own con-

science, not those of the world. What is it which makes one man a really great painter where the many fail around him? It is that they are looking with the eyes of the world; he is looking with his own eyes, and seeing what they fail to see. You remember what Turner said—Each man saw according to the power of sight that he brought with him. And that power of sight such as he had, and such as other great men have had, comes simply from the fact of the freshness and keenness and truth of their perceptions—perceptions belonging to the individual and differing altogether from those of the crowd around them. When, on the other hand, Ruskin spoke of the Academy as in great measure like a gigantic edition of the *Illustrated London News* he meant that a large number of the artists were thinking the world's thoughts, were looking with the world's eyes—not using their own eyes and their own thoughts, and therefore, in the expression of these thoughts became trivial and poor. I know that it can be the lot of but few to stand out far above the rest of their fellows, to mould public opinion, or found a new school of art, but it seems to me possible for each one of those to whom I am speaking to be true to their own self—not to bow down to the world that is round them, to build up their own standard of the true and the false, to cherish and cling to the freedom of the inner self, and in doing so to raise here and everywhere the spirit in which we look on art in this country, to make our perception more individual, and therefore more truthful, more fresh, more vigorous."

CONTEMPORANEOUS ART.

A LECTURE entitled, "Contemporaneous Art, as Illustrated by the Great Paris Exhibition of 1878," was delivered by Mr. J. Forbes Robertson before the members of the Society for the Fine Arts in the large gallery, at 9, Conduit-street, Regent-street, W., on the evening of Thursday last week. Mr. James Edmeston, F.R.I.B.A., presided.

Mr. Robertson said, that whatever the motives of the originators of the Exhibition in Paris, about which various theories had been put forward, the issues were momentous in the extreme, both in an intellectual and artistic aspect. The wonders of the world had been gathered together for universal admiration, promising that the sword would sooner or later be transformed into a ploughshare. To deal with a moiety of them only in a brief hour would be nothing less than presumption. We are first struck with the art aptitude of the French people in statues and their accompaniments. We could not have produced such an effect. Passing through the great hall, the first set of rooms was devoted to the British schools; and these, by universal consent, were creditable to ourselves. British characteristics may be summed up in the word modesty. The French excel in handling—the facile use of the pencil comes to them by nature. America and Italy follow the British art section. America does not show in sculpture so successfully as it might have done, Boston submitting nothing. French influence is strongly marked in all American exhibits. Wiley has a good picture, but it is strongly French. Dana is a remarkable sea-painter. Thirty years ago America could scarcely exhibit anything; now it occupies a foremost place. Italy, once a painting country, is now one of sculpture. It still, however, has artists with serious aims. The Spanish influence is, however, felt throughout Italian work. The French school is also seen in Italian work. Italy's work in sculpture is varied; its level, however, is not maintained throughout. The figure of the late Pope is excellent. With political liberty vigour has been imparted to Italian art. Austria has some grand pictures, as the entry of Charles II. into Antwerp. Portraiture is also well represented. Hungary only fills one salon, and its work is quite up to the Austrian standard—rich in texture and colour. One picture, a Miltonic subject, received the highest prize that could be awarded at the Exhibition; strength of representation and beauty of effect. Hungarian art is excellent, but not special. Sweden and Norway are devoted to sea subjects and landscapes. Their technical qualities are of a high order. There is French influence, however, as in manners and customs. Charles XII. of Sweden's funeral is Swedish, and impressive and characteristic and national. The Norwegians have no historic work of importance, although in general effect

they cannot be said to be inferior to the Swedes. Denmark has little on the walls. The manner is tender and sympathetic, but on the whole weak. Portugal does little more than rise to the level of a provincial English town. Greece shows work in a smooth, conscientious way; but there is nothing of classic Greece. Switzerland has some good pictures, but nothing calling for special attention. It is also rich in art productions, but often there is a touch of German dryness. Russia is a small state in art, however large in area. Its students only who have studied in Paris come to the front with credit to themselves and honour to their country. The activity of the Russian artist is remarkable. Germany and Belgium are vigorous sometimes to coarseness; amounting sometimes to unflinching realism. Holland does not have many pictures, but its sea pictures are perfect. What, again, is to be said of France, that has grouped these treasures? Paris is the art school of the world; embracing all schools, and towards which pilgrims flock from every land. Its roll of illustrious names is worthy of the admiration of the world.

THE HISTORICAL DEVELOPMENT OF PATTERN DESIGNING.

MR. WILLIAM MORRIS delivered a lecture on this subject at the Co-operative Institute, Oxford-street, on Tuesday evening, Mr. G. C. Warr in the chair. The progress and development of ornament were traced from its earliest records on Egyptian tombs and temples, its symbolic character being demonstrated. In the remains of Assyria this was still more developed; the sacred tree and serpent, the embodiments of the spirits of good and evil, were constantly repeated in more or less conventionalised form, and these emblems survived in ornaments of every style to the latest Gothic and Renaissance. The love of delineations of life and of flowers was universal. The progress of art in Persia was also adverted to, and the winged bulls and lions were referred to as derived from more ancient Assyrian and Babylonian sources. The incised and intricate patterns of Persia, India, and other eastern lands were shown to have a common growth. Greek art exhibited a steady growth of refinement and grace to the Periclean age, but there was throughout a coldness and constraint, and a painful sense of unattained perfection. Ornament was everywhere subordinated to architectural form, and was of simple character, and derived from Eastern sources. The common error that the Greeks had little perception of the beauty of colour, and that they were even colour-blind, was exposed and contradicted, the lecturer urging that Greek colour-nomenclature and habits of thought referred rather to the tone and brilliancy than to precise hue. As the Greeks decayed the Romans increased in power and influence, and to them, or rather, perhaps, to the vast assemblage of nations brought into intercourse under their imperial rule, the world owed it that architecture became an art to be studied, and not a conventional form of building. The arch was introduced as a building feature of practical use by the Romans, and fresh combinations of parts, constructional innovations, and decorative experiments were tried with the daring of engineers rather than with the skill of architects. With the change of the seat of government to Byzantium a further development of art took place, the influence was being felt to the present day. The exuberant richness and wealth of ornament then employed in Constantinople had furnished suggestions to the whole world. Incidentally, the Mosque of St. Sophia, in that city, was referred to as the most beautiful building in existence, and the delicacy and refinement of its ornamentation was illustrated by a large coloured diagram of one of the capitals, the bell of which was completely mantled by crisp fern-like leaves, spreading from the astragal. Arab art was really a combination of Greek, Coptic, and Byzantine, but owed its chief impulse to the last source. The gradual spread of Byzantine ornamentation and architectural style over Europe formed the concluding part of the lecture. These Eastern ideas overran Italy, spreading into Lombardy, where they were adapted with a new force and beauty, and the builders, who had been rugged and coarse, displayed work of a lovely and delicate character. From thence the new ideas penetrated into France, and so passed into Germany, where the ornamentation was so much admired that on the

banks of the Rhine the mode, now known as the Romanesque style, had never been abandoned. From the Rhine it was transported to England, and was developed on new lines, till the Italian phase, introduced by the Normans, supplanted and partially absorbed it, and Italian phases, later on, again banished the Gothic modes of thought. The tide still swept westwards and northwards, far-off Iceland being at length reached. Mr. Morris urged that no art was worthy of the name which was not at once a pleasure to the artist to produce and to the user to behold.

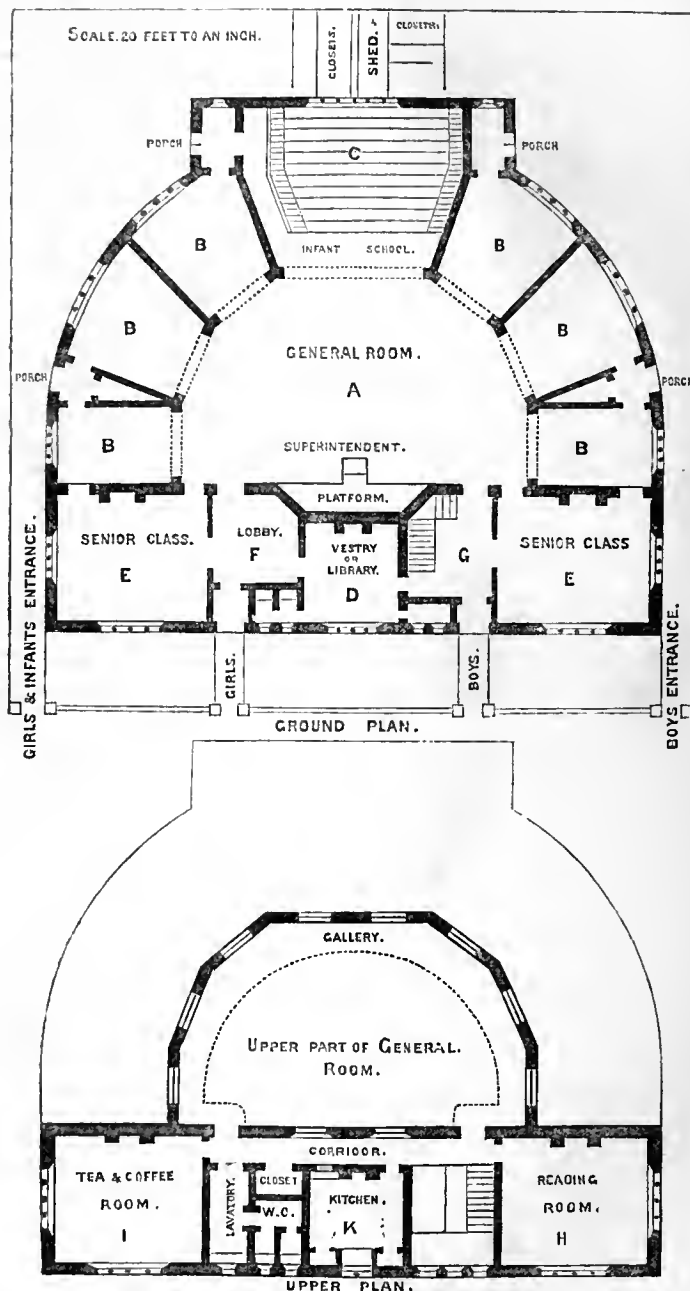

SUNDAY-SCHOOL BUILDINGS.

A SERIES of articles on the above subject has recently appeared in the *Church Sunday School Magazine*, written by Mr. C. G. Maylard, A.R.I.B.A., which offer some suggestions for the consideration of builders of Sunday-schools. It will at once be admitted that the present buildings which answer this purpose in our towns are deplorably defective in planning, uncomfortable, and in most cases quite inadequate for the purposes of Sunday-school teaching. In the majority of instances, they are hired rooms in unhealthy localities, low, ill-lighted, and unventilated. Mr. Maylard, who has given, we believe, much attention to the wants of Sunday-school building, points out the value of separate class-rooms for the use of scholars whom it is desired to attach to the Church. He says justly, "in every case, whether a large or small school, there ought to be one general room with the necessary class-rooms in number according to the size of the parish. It is of paramount importance that these adjuncts to the school should be as numerous as possible, consistently with the extent of the population, and the smallest school should not have less than two." It is doubtless, as the author points out, the policy of the clergy to provide separate rooms to prevent the elder members leaving at a time when they ought to become attached to the Church. Advanced scholars do not care to mix with younger children, but if other rooms were provided they could meet as Bible-classes. These rooms would also be available for other uses, such as instruction for confirmation, servants' classes, reading, &c. If, further, these separate rooms could be made capable of being thrown into one general room, an additional advantage would be insured, as such a large room could be turned to various purposes for parochial meetings or entertainments. The author shows first how a school for a small parish may be planned. He proposes a general schoolroom 40ft. by 30ft., with two class-rooms at one end, each 18ft. by 14 ft., opening into the general room by folding or sliding doors. Each class-room to have its own entrance. At the other end of school-room is shown the main porch entrance at one corner, a recess for superintendent's desk in middle, and a small class-room with separate entrance at the other corner. Such a general schoolroom will accommodate at the usual allowance of 8ft. superficial to each scholar, 200 children, and the class-rooms 20 for Bible-classes or 40 infants as a gallery. The room could easily be improvised into a church or used for mission services by making the recess a chancel, and the small class-room at side a vestry, and by removing the doors of the two class-rooms at the other end; in this way 300 people might be seated. It is pointed out that the room may be divided by curtains. Another plan on a similar principle, but with separate rooms for the boys and girls is given. The arrangement is that of an inverted T, the vertical part being the boys', and the horizontal part the girls' school. At the end of boys' school two class-rooms are shown 14ft. by 14ft. each, opening into it and with separate entrances, also two other class-rooms each, 22ft. by 14ft. in the angles of large rooms, available for either school. The large schoolrooms are 40ft. by 30ft. for the boys, and 56ft. by 30ft. for the girls; the two being capable of being thrown into one by the removal of a partition. The class-room are also arranged to be thrown together for mission services, &c. The school is capable of accommodating from 500 to 600.

Mr. Maylard next proceeds to show the advantages of the "radiating" or American system—a plan which has partially at least been introduced into this country. A combination of the rectangular and radiating principles is shown by a plan of a school at Wandsworth, by Mr. J. Weir, architect, designed for the Wesleyan

Sunday-school Union. The school-room is 51ft. by 34ft.; at one end are 4 class-rooms arranged round a segment—in plan the arrangement looks like an arch with 4 vousoirs, segmental in its inner curve, and with straight extrados. At the other end is a shallow recess and platform, which might be used as a chancel. But the author advocates a more thorough carrying out of the radiating plan, and furnishes two plans to illustrate his remarks. One of these represents a simple semicircular building, the central space being the general school, 30ft. radius from the superintendent's desk, which forms the centre of chord line or diameter, a platform recess being behind. Six class-rooms, each 22ft. by 18ft. are arranged round the outer line of this semicircular

rooms at the sides, and an infants' class-room with separate entrances. We quote the author's description: "On the ground-floor is a central room A, 40ft. by 20ft. for 150 scholars; 6 radiating class-rooms B, for 156 scholars, and an infants' class-room C, for 85 scholars, all with separate accesses, and all available for use as one large room to seat 500 people. The position of the desk of the superintendent is such that from it he can see every scholar in all these rooms, and the same would be the case when used for Church services. A large arched recess is at the back of his desk with a platform for speakers on occasions of parochial meetings. A vestry or library, D, is arranged at the back of the platform, with lavatory, water-closet, and book cupboard.

space with radiating division walls, and separate entrances and wide openings with folding doors towards the schoolroom so that every scholar can see the superintendent, while each class-room is equidistantly placed from the desk. Such a school would seat 180 children in eighteen classes, while, with the class-rooms, it would accommodate nearly 600. A front or straight range of building contains two Bible class-rooms for adults, committee-rooms, stairs, and lavatories. It is easy to see that this plan is well adapted for a large parish, lends itself admirably to parochial or other meetings by removing the folding doors and erecting galleries over some of the class-rooms—an arrangement that would enable 1,000 people to be seated. We are indebted to the author for the use of the accompanying plan which explains this arrangement more fully. As will be seen, it contains a general room with radiating class-

Right and left of this room are entrances for senior boys and girls respectively, with a class-room E, for each to hold 36. The total number of scholars thus provided for is 463." F, is a large waiting lobby for use of those who get books, while C is a lobby and stairs leading to a reading-room, tea and coffee-room, and kitchen, in connection in centre. A gallery round the general room could be readily constructed, available for parents on prize distributions, and it is also pointed out that the two senior class-rooms are sufficiently high to obtain a mezzanine story for caretaker's rooms over lobby and vestry. The general room would be lighted by a series of windows above the openings of class-rooms, the latter being kept low. From this plan it is clear the space is occupied in an economical manner, and that the system adapts itself to square sites. On the rectangular plan of building, a large part

of such a site becomes necessarily occupied by projecting class-rooms, and the land is more cut up. Referring to cost, the author bases his calculations upon the London market, and allows 6d. per foot cube. The small rectangular plan we first described would at this rate cost £1,150, or a little over £4 a child; the larger plan for 550 scholars would cost about £2,350, and the large radiating school for 700 scholars would cost about £3,000; the one we illustrate about £2,500, these sums including external conveniences and boundary walls, but no fittings. Various details and sanitary hints are given by the author in his concluding paper, to which it is here hardly necessary to refer. The selection of a sunny aspect for the windows is of course desirable; heating is best effected by hot-water or air, with open fireplaces in the class-rooms if necessary. Air-chambered grates, drawing their air-supply from the outside are recommended, the heated air escaping through a grating at the top, capable of being regulated. As regards the ventilation, separate ventilating flues in connection with the smoke-flues are advocated, openings for the exit of vitiated air being made near the ceiling, having a Sherringham, Boyle or Arnott's valve. Draught is maintained by gas-jets placed just above the valves in the flues, and lighted by an opening with close glazed door. Sun burners with shafts are also recommended for flat coiled schools. The fresh air is proposed to be introduced behind a wood dado, having a space of about 2in., with movable hinged flaps for the admission of air. With regard to the class-room doors, the author prefers those which slide up from the floor into the wall, hung at the sides like sashes, to folding doors; in this case the general school would have to be top-lighted or arranged as a domical lantern. Mr. Maylard's suggestions are sensible, while the system of arrangement he advocates is strictly scientific.

MR. ALMA TADEMA'S PICTURES.

THE pictures painted by Mr. Alma Tadema for this year's Academy Exhibition were on view at Messrs. Pilgeram and Lefevre's galleries in King-street, St. James's-square, during the latter end of last week. We scarcely need to tell our readers that they well sustain their author's reputation; and as examples of consummate *finesse*, combined with a power of realistic effect, we have seldom seen finer works, even by this master. "Down to the River," the largest picture, is a grand piece of painting that has more historic interest and suggestiveness in it than the simple title would lead us to expect. It represents one of these noble stone bridges that might have spanned the Tiber or some classic river in its palmiest days. An Italian lady with a little girl are just seen on the lower left hand corner of the canvas descending a flight of steps at one end of the bridge. The head of a boatman, with his hand pointing to the river, is apparently soliciting hire, while below him, on a return flight, is seen the head of another dark mulatto-like man, also eager for engagement. These figures, or rather heads, are wonderfully painted, and give a scale to the grand perspective of the bridge which crosses the river. To add to the effect of descent, the artist has cleverly introduced the back of the head of a golden-haired woman in the half-landing. We cannot speak too highly of the solid luminous side of the bridge, and its reflection in the smooth swelling ripple of the blue river which flows beneath the arches. It has been objected by some critics, who affect accuracy, that the arches are not in true perspective, the second span being of a different curve to the others adjoining it; but it is evident the artist has here intentionally shown a bridge in which the arches vary, and are of different width and curvature, as may be seen by the sudden drop of the line of the parapet in the distance. The end openings were evidently intended to be different, and we can hardly impute to a painter of such masterly architectural detail a want of correct drawing in so easy a matter. At the farther end of the bridge a triumphal arch spans the roadway, while in the spandrels are introduced pedimented niches with bronze statues. These are marvellously painted, and stand out in the sunlit recesses. The cornice, mouldings, and detail generally are very carefully drawn, and the structure reminds us of an Italian bridge that spans the Arno. The colouring, however, is exceed-

ingly rich and sparkling, and the handling spirited; the deep blue of the sky over the warm-toned stone, and the rich colours in the water, make up a glowing canvas. "A Hearty Welcome" is a small panel subject, representing the interior of a conservatory, surrounded by buildings of Italian character. Flowering shrubs, cactuses, sunflowers, poppies, and other plants are introduced, with a truth, delicacy, yet breadth of manipulation that is remarkable. Viewed with a large magnifying lens, the blossom and the leafage look like reality itself; every leaf and flower is delineated with a microscopic faithfulness which only a photograph can give, and yet the eye is not distracted with minutiae. Mr. Tadema seems to possess the power of rendering his pictures with faultless and minute detail, at the same time that he never wears the observer. His foliage is nothing but a dexterous effect produced by a dry brush with masterly precision, and the same may be said of his sunflower and blossoms. Figures of a lady and girl clad in Italian garments are introduced, and, we understand, are portrait studies of Mrs. Tadema and her little girl, while a dark-robed figure is approaching by a staircase, intended for the painter himself. The play of sunlight on the coloured pilasters, the carved marble entablature which appears in the distance, and the figures are marvellous. In the "Feast of Pomona," another even smaller cabinet picture, the artist has given us an episode of old Roman history, in which Pomona, the divinity of garden produce, is the subject of festive dance. Mr. Tadema seems to have caught the very spirit of the festival, and we might imagine his picture to be almost a reproduction in colour of Varro's description of these special services to the honour of the tutelary goddess. The apple-tree, with its blossom, round which the figures are shown dancing, the frescoed garden wall, over which a fringe of bright green leaves and blossom appears; the altar; the marble border and hyacinths, are wonderful in their microscopic minuteness and spirited execution. In "The Time of Constantine" we have an episode of old Roman life, told with similar dramatic power. The story told is exceedingly simple. A wealthy citizen is entertaining a friend in his garden. Both are seated, amused by the begging attitude of a dog, which is resting on its hind legs. But the surrounding adjuncts make up the picture, the most striking point in which is the grey, cold marble and statuary in the shade of which the host and guest sit, the reflected green light on the coping of wall, and the bright green leaves on the other side. We can almost fancy, as we look into the picture, the reality of the marble. Another small piece, in water-colour, entitled "Strigils and Sponges," is probably suggested from the old Roman Bath. The stooping figure of the undressed lady in the fountain, and the attendants—one dark, and the other with golden hair—the transparency of the water, the splash in the basin, is almost suggestive of allegory. The only regret we feel is that these exquisite cabinet pictures should have been painted so small, worthy as they are of larger canvases; and unless placed within accessible distance, we are afraid they will be lost by the side of larger and bolder pictures. Mr. Alma Tadema can paint both large and small pieces with equal boldness and delicacy; but these pictures are almost as surprising in their disparity of scale as they are in dexterity of execution.

IRON PIERS.

THE employment of wrought iron for the piles of bridges, piers, and other structures, has necessitated attention to bracing and other modes of connection and strengthening. Bridge piers usually consist of a number of piles sunk into the bed of river either by screws or pile-drivers, connected together by cross braces, the tops receiving caps, upon which the girders rest. Clusters of two, four, or more columns or piles, connected by ties, form the piers, and these are generally braced together by angle-iron bolted to ears or lugs, which in cast-iron columns are cast at intervals in the height. We here call attention to one or two modes of connecting piles of wrought-iron. One very useful method employed in structures of the class we are considering is to join the bracing bars to the upright piles or columns by means of clips, which surround the column on three sides and project as

lugs, which latter receive the bracing bars. These are generally round, made flat at the ends, with eyes, and are bolted through the lug or projecting part of clip. One advantage of this method of connection is that the clip may be adjusted to suit the bars, or rather the unsupported length of pile. In adjusting tie bars the screw shackle is employed, by which the length of tie can be regulated to a nicety by turning the shackle. This kind of adjustment is evidently required where the piles cannot be driven with accurate verticality. The sizes of these bracing bars and ties must in all cases be regulated according to the requirements of each case, and no rule can be given. The fact is that bracing of this description is exposed to strains of an irregular kind that cannot be estimated. Mr. Stoney, in his able work on the "Theory of Strains," observes: "Cross-bracing generally fulfils two functions—it acts as a horizontal web holding the compression flanges at short intervals in the line of thrust, and thus preserving them from lateral flexure, to which all long pillars are liable; it also braces the whole structure in a horizontal plane, stiffening it against vibration, and to resist the side pressure of the wind." He also recommends counterbracing the cross-bracing. In the case of braced pillars, the same writer remarks: "In long pillars it is desirable to connect each pair of compression bars by internal cross-bracing." He, in fact, regards the pillar as a girder, each of whose flanges is subject to a longitudinal pressure. From Hodgkinson's experiments on plate-iron tubular pillars it is probable that the strength of braced pillars is within certain limits independent of their length, for internal bracing is generally somewhat stronger than theory requires. Mr. Stoney adopts in practice 4 tons per square inch of gross section (excluding the cross-bracing) for the working strain of wrought-iron braced pillars. He regards each bay of a braced pillar as a pillar with rounded ends. It is obvious such a pillar resembles the compression flange of a girder, and this is the right manner of regarding it. As regards the sectional forms of braces, angle-iron seems to be admitted the best to resist vibrations, as long, round bars and flat ties offer little resistance to gusts of wind or violent waves.

The modes of lengthening pillars of wrought-iron are by couplings and flanges. Couplings are best made of steel, secured by bolts. Flanged rims, through which bolts pass, are generally adopted in cast-iron uprights and pillars, though various ingenious modes of lengthening will suggest themselves to the skilful engineer and architect. In the construction of iron light-houses and beacons, considerable opportunity for structural and artistic modes of connection offers itself. As a general principle, however, we consider clusters of pillars, disposed in T shaped, triangular, and quadrangular forms, braced together, to be the stiffest and most satisfactory mode of erecting structures of this class.

THE BUILDING TRADE AND THE BY-LAWS OF THE METROPOLITAN BOARD OF WORKS.

ON Monday a numerous deputation waited upon Mr. Cross at the Home Office to ask him to withhold his approval from the by-laws promulgated by the Metropolitan Board of Works under the 16th section of the Metropolitan Management and Building Acts Amendment Act, 1878. Sir James Lawrence, M.P., and Mr. O. Coope introduced the deputation. The by-laws were framed to prevent the erection of "jerry" dwellings—houses erected of bad material on plots of land which in many cases had been mere "lay-stalls" for garbage from London dust-holes. These houses, having had their imperfections covered with stucco, were sold at an enlarged, or, as it has been called, an "improved" ground-rent to persons who found too late that they had become possessed of insanitary dwellings constantly needing repair. The deputation, it was said, did not represent the large builders, but the men who by their brains had made their own way. Sir James Lawrence declared that some of the by-laws made by the Metropolitan Board to govern the erection of buildings were impracticable, and it would be impossible to carry them out. He objected to the rules that concrete was to be used in all cases under walls, and that the filling up of holes under houses to be built was to be with

"hard brick rubbish, or other similar material." He also objected to the provision that "good square, sound, well-burnt bricks" should be used for the internal walls as well as for the external walls, and to the regulations for the composition of the mortar—"good lime and clean, sharp sand, which has been properly washed, or grit, in the proportion of one of lime to three of sand or grit"; and he regarded the rules as placing unnecessary restrictions upon builders. He also criticised the powers given to the district surveyors under the rules. Mr. Coope said he held that it was important that houses for the working classes should not only be constructed with a due regard to the necessities of health, but they should be cheap, in order that rents should be kept down. He knew that in some parts of London houses had been so built that it was impossible they could be healthy dwellings; but he thought that consideration should be given to the point that while care was taken to guard against such erections, there should not be rules to prevent the erection of cheap houses for the poorer classes. Several builders then addressed the Home Secretary, and some of them expressed themselves as very impatient of the powers given to the district surveyors, urging that sufficient safeguards for the public existed before the appearance of these rules. The rules themselves were declared to be "an interference with the liberty of contract," as against "freedom of action," and it was stated with some bitterness that the reports of Dr. Tripe, the medical officer of health of Hackney, regarding erections called dwellings in that district, had led to the stringency of these rules, which, if carried out to the full, would be very detrimental to those rent-paying classes of London and the suburbs who paid between £20 and £50 a year. Mr. Cross, in reply, said that the Metropolitan Board of Works had prepared these rules, and that body was empowered under statute to prepare building by-laws in order to secure the public health and the public safety in the area of the metropolis, such by-laws when approved of by the Home Office having the full force of law. Whether the objections which had been raised by the deputation as to the too great stringency of these by-laws were well founded was a matter which should have his most careful consideration; more than that he could not say. The deputation then retired.

BRITISH ARCHEOLOGICAL ASSOCIATION.

THE eighth meeting of the Session was held on Wednesday last, Mr. H. Syer Cuming, F.S.A. (Seot.), in the chair. The progress of some excavations for building purposes, in the Borough, Southwark, was reported by Mr. Earle Way, who described a large number of Roman relics found there. These consisted of fragments of earthenware vessels of large size, and a perforated flint, the "Hag stone" of popular superstition, and which was hung upon stables to prevent the horses being ridden by the hag, as the effects of nightmare were called. Its occurrence 15ft. from the surface appears to warrant the belief that the superstition was known to the Romans. Mr. Cuming exhibited a beautiful chataleine or "equipment" of Pinchbeck's manufacture and metal. Mr. Loftus Brock, F.S.A., produced in illustration of one of the papers, a large collection of Greek and Etruscan pottery, exhibiting much diversity of form. Dr. Phené called attention to several remarkable peculiarities of the articles. Mr. Thos. Morgan, F.S.A., then read an elaborate paper upon Etruscan Art and having reference to the remarkable tomb recently discovered at Praeneste, in Palestine. After tracing the course of art among this ancient people through the Archaic, the Greco-Etruscan, and the Romano-Etruscan styles, illustrating his remarks by a large collection of plates and drawings, he proceeded to describe the tomb in detail. It is an oblong sepulchre, the sides corresponding to the points of the compass, 18ft. long by 13ft. broad. The ceiling was flat—in this particular, and in the style of the ornaments found, indicating a high antiquity. There had been a bier in the centre, where was found a plate of gold with small amulets. Many ornaments of Egyptian character were found, together with bronze nauges, silver dagger-sheaths, and iron handles. The period of the interment might with safety be assigned to the 6th century before Christ. The whole of the objects have been purchased by the Italian

Government for 70,000 francs. Dr. Phené reported the results of excavations made by him in Etruria, illustrating his remarks by a large collection of drawings, among which the tombs of Castel d'Asso, of vast extent, were dwelt upon, and the opinion expressed that some of these had originally been the dwellings of the occupants. They are cut out of the solid rock, having what appear to be doors, but the openings are elsewhere.

MR. STREET'S RESIGNATION OF THE V.P. OF THE R.I.B.A.

WE are informed that the reason given in our announcement last week for Mr. G. E. Street's retirement from the Council of the R.I.B.A.—which was taken from the Institute Circular—is incorrect, and omits all reference to the reason stated by Mr. Street in his letter to the Secretary of the R.I.B.A., which we publish.

[Copy.]

DEAR MR. WHITE,—This year (and next year it will be same) so much of my time is taken up by serving on the Council of the Royal Academy, that I really have no time to spare for other similar duties, and as under the present system at the Institute of Architects any chance of getting new blood into the Council ought to be seized, I feel that I ought to resign my post as Vice-President and Member of Council. Will you be so good, therefore, as to take care that my name is struck out of the house list?—Believe me, yours very truly,

(Signed) GEORGE EDMUND STREET.

14, Cavendish-place, Cavendish-square, W.

March 20th, 1879.

W. H. White, Esq., Secretary R.I.B.A.

EXPERIMENTS ON THE TESTING OF PORTLAND CEMENT AND BRICKS.

IN a recent discussion on a paper read by Mr. Maclay, before the American Society of Engineers, some important facts relating to the subject of cement induration were cited. Mr. Don J. Whittemore very justly observed that in experiments undertaken in relation to cements "nothing satisfactory can be done without first taking every precaution and refinement in measuring, weighing, and manipulating that can be devised in preparing specimens, and that the resulting tests are of little relative value unless all specimens are exposed to the same temperature." As Mr. Maclay pointed out in his paper, low temperature arrests the indurating process as it does chemical action generally, and Mr. Whittemore says his own observations lead him to the belief "that the action of heat and cold upon mortars of American hydraulic cements is more erratic in character than upon Portland." He also says that water which has absorbed the most carbonic acid will always be found the best for immersion in hastening the indurating process, and this statement he corroborates by the example of sewer-water immersion, though dirty water may contain elements injurious to the cement. The same authority gives the result of placing briquettes of pure cement in a bath of water vapour, constantly saturated with carbonic acid, for a period of 52 days. While these showed a tensile strength of 345lb. per square inch, specimens of the same cement immersed in fresh water for the same period, broke at an average of 156lb. per square inch. We quite agree with the remark, that no system of testing is complete which does not give the values for strains such as crushing and breaking, as well as tensile strength—the favourite test. Engineers and architects specify a certain tensile strength for Portland cement, but in nine cases out of ten, the cement is seldom required to resist any other force than compression, and it is evident the tensile resistance does not always indicate the resistance of cement to crushing or cross strain. Mr. Whittemore's experience in testing is that for at least two years, cement mortars never retrograde in tensile strength, but increase approximately in proportion to some root of the age; for a fair quality of Portland the index of this root is 10, and the expression is

$S = A \sqrt[10]{T}$ in which S = strength at the age T, and A is a factor determined experimentally, by dividing the known strength at any age of sample, by the 10th root of its age. It is shown that this formula accords very closely

with Mr. J. Grant's observed strengths (p. 122). If the strength value of Portland cement is to be determined only by tensional strength, says the author, the sooner the usual seven-days tests are discarded the better, for substitute tests at 20, 40, and 60 days. Mr. F. Collingwood referred to some results of experiments on American cements and bricks made at the East River Bridge, a diagram of which is given in the "Transactions." One of the chief points of interest in this diagram of curves "is the rapid increase in strength up to about 7 days, then a depression in almost all cases up to the 14th day, and then the marked and steady increase. The first period would seem to indicate the close of the formation of hydrates, and the next rise the beginning of the formation of crystals of silicate of lime, &c." The experiments also indicate another important fact, "that there is no certain ratio between tensile and compressive strength, and that the ordinary tests are of little value in determining the true relative merits of different cements. Mr. Collingwood's tests of brick under compression and tension are useful; those of whole bricks on end gave a minimum compressive strength per square inch in ten tests of 1,600lb., a maximum of 3,060lb., and an average of 2,065lb. On the side the figures were—2,900lb. minimum, 6,400lb. maximum, and 4,612lb. average. Ten bricks were then broken on the flat, and to the surprise of experimenters, the minimum gave 2,669lb., maximum 4,153lb., and average 3,371lb. The less amounts are attributed to imperfect bearing surfaces. As regards tension, the minimum strength recorded was 90lb. per square inch, maximum 358lb., average 168lb.—about equal to the best cements at the end of 21 days. The conclusion derived from these experiments can only be that brickwork has considerable strength as a beam—one that is invariably borne out by old and good brickwork, where the joints are properly filled up.

COMPETITIONS.

TIVERTON.—The Governors of Blundell's school, Tiverton, met on Monday, when the plan of Messrs. Haward and Son, Exeter, for the recreation of the new buildings at Horsdon was selected as the best and approved, provided contracts could be obtained within the sum specified, £11,000.

CARDIFF.—The first premium of £50 has been awarded to Mr. G. A. Lundie, M.I.C.E., of Cardiff, for his scheme for the sewerage of the town. It is proposed to deal with the sewage on eight acres of land by intermittent downward filtration, and the whole of the works are estimated to cost about £5,000. The local board advertised for plans, specification, and tenders, and there were twenty competitors.

SCHOOLS OF ART.

SOUTHAMPTON.—The annual distribution of prizes to the students of the Southampton school of art took place on Thursday week. The report stated that in April last the students' drawings were submitted to an examination at South Kensington, when eight works were selected for national competition, four third grade prizes were awarded, one free studentship was granted, six students were commended for advanced, and six for elementary work. Three of the prize works—a painting from a bas-relief by Miss A. Colson, and two landscapes by Mr. R. McFadden (one of these was purchased by the Department Examiner)—were publicly exhibited at South Kensington during last autumn. The other prize works were two heads from life by Miss E. Harty, and a drawing from the figure and from ornament by Mr. G. H. Thompson. In May last the annual examinations in freehand, model, geometrical, perspective, anatomical drawing, and designing took place, when forty-eight students sat. They worked twenty-eight papers successfully, thirteen of them being excellent.

The peal of bells at Ashburton Church, Devon, are about to be raised from six to eight. The additional bells are being manufactured by Messrs. Blows, of Birmingham.

Last week the erection of one of the great towers of the Forth Bridge, on the Island of Inchgarvie, was commenced by Mr. John Waddell, contractor, Edinburgh. The towers, of which those on Inchgarvie are to form the centre supports, will, when the ironwork is complete, be upwards of 500 feet in height.

Building Intelligence.

ASTON.—A new assembly room at Aston, near Birmingham, was opened on Monday. The assembly room will seat 4,000 persons, and is, with the stage, 220ft. long and 87ft. 3in. wide. The height from floor to roof is about 50ft. The prevailing colours of the decorations are amber and blue, interspersed with maroon, the ornamental portions being relieved with gold. An aquarium is not yet completed. In length it will be about 340ft., and in width 56ft. The exterior is of red and white brick, and the building is surmounted by a tower nearly 90ft. high. The chief promenade is 311ft. long, and on either side are large tanks similar to those at the Brighton and other aquariums. Encircling the top part of the building is a terrace promenade, 330ft. in length. The superintendence of the aquarium is undertaken by Mr. W. A. Lloyd. The buildings have been designed by Mr. Thos. Naden, of 14, Temple-street, Birmingham; the aquarium has been erected by Mr. John Garlick; and the assembly room by Mr. Wm. Bloore.

HEXHAM.—On an eminence near the outskirts of Hexham, has been erected a pile of buildings, henceforth to be known as the Tyne-dale Hydropathic Establishment. They are built of stone in the Italian style by Messrs. Reed, contractors, Newcastle, after the plans of Mr. W. L. Newcombe, architect, Newcastle. The building forms three sides of a square, the principal entrance facing east, with a second main entrance on the south; while the baths, on the west, fill up the fourth side of the square. It consists of the basement and three stories, each flat, with slight variations, being a repetition of the other. Each bedroom is exceedingly high, and any bad air which might accumulate is carried off by one of Boyle's patent ventilators. Dr. Richardson's plan of cooking in an upper room has been followed, and the kitchen, the floor of which has been cemented, and which is fitted with Benham's cooking range, is situated over the dining-room, so that all objectionable odours from the cooking find their way upwards and outwards. The building, including everything, has cost £13,000.

HOLYHEAD.—The parish church of St. Cybi, Holyhead, one of the oldest and most interesting ecclesiastical antiquities in Wales, its foundation presumably dating from A.D. 650, has just been reopened after restoration from the designs of the late Sir Gilbert Scott. The old galleries have been removed, the interior has been excavated to a depth evidently the original base of the building, and the roof replaced by one of carved oak, the centre boss in the nave bearing as a record of the restoration the crest of the Stanley family, who have subscribed towards the outlay of £6,000 expended upon the work.

KINOUSSIE.—A new Free Church was opened near the railway station, Kingussie, N.B., on Thursday, the 3rd inst. It measures 56ft. by 40ft., and is 21ft. high to plate of walls. It is built of blue whinstone, and the fittings are of pitch-pine. The chief entrance is at the south through a porch surrounded by turret and bell, while at the north end is a vestry. On the platform is a chair in carved walnut and maroon plush. There are galleries on three sides, and the roof is an open one. The style is Gothic, and accommodation has been provided for 600 people at a cost of £1,600. Mr. Laurie, of Inverness, was the architect, and the chief contractors were:—Masonry, Messrs. Mackenzie and Macdonald, Kingussie; carpentry, Mr. Laing, Forres; slating, Mr. Catanach, Newtownmore; plastering, Mr. Alves, Forres; plumbing, Mr. Ross, Kingussie; and painting, Mr. Chisholm, Kingussie.

METROPOLITAN BOARD OF WORKS.—At this board on Friday it was reported that the two new fire-brigade stations in Chapel-place, Brompton-road, and at Shooter's-hill will shortly be ready for occupation, and it was decided that twelve men be added to the staff of the brigade, and that four new manual engines, two fire-escapes, thirty 100ft. lengths of rubber-lined canvas hose, and eight manual suction-pipes be obtained, to be placed at the new stations. In reply to questions, Mr. Edwards stated that the various makers of fire extinction apparatus were asked some time since to tender for the supply of four steam-engines, &c., to those now required, and Messrs. Shand and Mason's tender was the lowest re-

ceived (£380 each), against Messrs. Merryweather's tender of £390. The engines had been obtained, therefore, from the former firm, and it was proposed also to obtain the appliances now required from Shand and Mason's. Considerable discussion took place on the general question of tenders, but eventually the proposal of the committee was approved, and also the purchase of engines. The fire brigade committee were authorised to obtain a site in the neighbourhood of Sloane-square on which to establish a fire-brigade station. A contract was sealed with Messrs. Laing for erecting a keeper's lodge on Tooting Common. The engineer reported the death of Mr. James Macleary, surveyor, who had been in the service of the board for twenty-five years. A letter was received from Sir H. A. Hunt, transmitting a copy of his final award in connection with the Old Pye-street Improvement Scheme, under the Artisans' and Labourers' Dwellings Improvement Act, 1875, deposited with this board as the local authority.

RADCLIFFE.—The new co-operative stores are now completed at Radcliffe. The secretary's office and board-room, each 30ft. by 22ft., are upon the first-floor. The news-room is a well lighted room 52ft. by 25ft., with a panelled pitch-pine ceiling handsomely furnished in pitch-pine, with newspaper stands, tables, seats, writing-desk, reference library, &c., all especially designed for the room. The library and conversation room are arranged in convenient juxtaposition. The remainder of this floor is occupied by store-rooms for the grocer. The exterior is a neat brick building with stone dressings. Decoration, wherever introduced, is composed of combinations of ordinary stock bricks. The work has been executed by local contractors at a total cost of nearly £15,000, from the plans and under the superintendence of Messrs. Maxwell and Tuke, of Bury.

SCHOLES.—At Scholes, on the Leeds and Wetherby line, a new Wesleyan chapel was opened on Wednesday week. The chapel, which has been built from the design of Mr. G. F. Danby, architect, Leeds, is in the Gothic style of architecture, and is built of pressed bricks relieved with black bands and stone dressings. The dimensions inside are 36ft. by 26ft., and 23ft. high, and it will accommodate about 150 adults; the roof is an open-timbered one, covered with dressed boards, felt, and Westmoreland slates. The principal contractors are Messrs. Marshall and Sons, of Crossgates, for the bricklayers' and masons' work; and Mr. J. Tomlinson, of Leeds, the joiners' work.

SCORTON.—A new church is being erected at Scorton, near Lancaster, and will soon be completed. It is in the 14th century phase of Gothic, and is built of local ashlar. The internal dimensions are: nave, 52ft. by 20ft.; north aisle, 52ft. by 13ft.; chancel, 31ft. 9in. by 20ft.; organ-chamber, 14ft. by 13ft.; vestry, 15ft. 6in. square; and south porch, 10ft. by 9ft. 6in. There is a tower 49ft. high, capped by octagonal oak-shingled spire, which rises 33ft. more. In this tower will be a peal of six bells from Messrs. Warner's foundry. The eastern window of church is filled with stained glass in five lights, the subjects being taken from the lives of our Lord and of St. Peter. The chancel floor is laid with tiles from the works of Messrs. Craven, Dunhill, and Co., of Ironbridge. The open benches and upper part of pulpit are of oak. The roofs are of pitch pine, felted and covered with Staffordshire tiles. The church seats 250 persons. The contract for masonry was taken by Messrs. Wilson and Kirby, of Longridge; and that for carpentry by Mr. Blades, of Lancaster.

An area of about 90 acres of land on Wandsworth Common on the right of the South Western line, and extending from the Wandsworth Prison to Garratt-lane, has been purchased by Mr. Robert Davis, and is about to be covered with residences for the middle-classes. The plans have been drawn up by Mr. T. G. Lynes, of St. John's-hill, Battersea, and as approved by the Metropolitan Board of Works, show a series of villas, averaging in cost from £800 to £1,000 each on plots, with 40ft. frontages, and depths of from 100ft. to 180ft. The contract for making the principal thoroughfare, to be known as Earlsfield-road, has been given to Messrs. Robert and George Neal, of Wandsworth-common; we publish the list of tenders sent in on another page.

The peal of eight bells in Brigg church has just been completed, by Messrs. Warner & Sons, bell-founders, of London.

More than Fifty Thousand Replies and Letters on subjects of Universal Interest have appeared during the last ten years in the **ENGLISH MERCHANT AND WORLD OF SCIENCE**, most of them from the pens of the leading Scientific and Technical Authorities of the day. Thousands of original articles and scientific papers, and countless receipts and wrinkles embracing almost every subject on which it is possible to desire information have also appeared during the same period. The earliest and most accurate information respecting all new scientific discoveries and mechanical inventions is to be found in its pages, and its large circulation renders it the best medium for all advertisers who wish their announcements to be brought under the notice of manufacturers, mechanics, scientific workers, and amateurs. Price Two pence, of all booksellers and news-vendors. Post free 2½d. Office: 31, Tavistock street, Covent-garden W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) for any part of the United Kingdom for the United States, £1 6s. 6d. (or 60s. 40s. gold). To France or Belgium, £1 6s. 6d. (or 35s. 30s.). To India (via Southampton), £1 6s. 6d. To any of the Australian Colonies New Zealand, the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

N.B.—American and Belgian subscribers are requested to remit their subscriptions by International P.O.O., and to advise the publisher of the date and amount of their remittance. If the last-mentioned precaution is omitted some difficulty is very likely to arise in obtaining the amount. Back numbers can only be sent at the rate of 7d. each, the postage charged being 3d. per copy. All foreign subscriptions, unaccompanied by an additional remittance to cover the extra cost of forwarding back numbers, are commenced from the next number published after the receipt of the subscription.

Cases for binding the half-yearly volumes, 2s. each.

RECEIVED.—E. H. E.—W. R. L.—S. J. N.—B. L. and Co. J. and H.—G. O.—G. E. H.—D. C.—J. H. B.—B. of A. F. I. and Co.

J. P. NORMAN. (We know of no work that gives exactly the information you seek, but there is an article on hydraulic machinery in Spurr's "Dictionary of Engineering," and, so far as mining appliances are concerned, in Ure's "Dictionary." Knight's "Dictionary of Mechanics" illustrates several forms of water motor, and gives brief explanations. Messrs. Bailey, of Salford, make water engines of different types.)—W. J. J. (Claridge's is the best. Mr. J. Farrell, Victoria Embankment, W.C., would probably send particulars on application.)—A. C. P. (We cannot interfere. We have already said all we have to say. You can, of course, reply to the rejoinders which have appeared if you wish, but we think the subject has already occupied as much space as it is worth.)—ENQUIRER. (The lighter body would occupy more time in its descent.)

"BUILDING NEWS" DESIGNING CLUB.

DRAWINGS RECEIVED.—East Anglian, Motto, J. Signum, Dunwich, M. with Leaves, Essayer, Factable, Osmore, Try, Veritas Vincit, Josephus, Orange Blossom, Be to its Merits, &c., Pogmore, Melina, Myletus, Steffano, Honey Dew, Nemo, Noah, Antediluvian, David Waterhouse (drawings of screen returned with thanks), N. Joyce, D. B. Dick, Toronto. (The drawings of houses contain nothing special, but we acknowledge their receipt with thanks.)

LAST OF SUBJECTS.—1. A school chapel for a village, suitable for 60 children, vestry, and recess for chancel to be shot off by a movable screen, cloak-room, class-room, and lavatory. Plan, 2 elevations and sketch. Scale, 6in. to the foot. 2. A sketch for a hall chimney-corner, showing seat. Opening to be 3ft.

Correspondence.

A SCOTCH PROVOST ON ARCHITECTURE.

To the Editor of the BUILDING NEWS.

SIR,—I inclose a paragraph from the *Scotsman* of to-day, from which you will see that the learned Provost of Greenock has been "going for" the Liverpool and Manchester Architectural Associations, because they ventured to express their disapproval of the penny-wise and pound-foolish course the Council were pursuing in cutting down their architects' commission from 5 to 4 per cent. What a wiggling, Sir, the R.I.B.A. would have got from the Provost if they had spoken out pluckily on the matter! It is said that England is the last country to take

up any general movement of the European mind, but how about Scotland? My object in writing this letter is to try and induce architects to stick together and form a real trades' union, to protect them against the shabby treatment of town councils and vestries, and they will then be able to snap their fingers at the abuse of a Scotch provost.—I am, &c.,

April 8th.

J. R. A.

THE PROVOST OF GREENOCK AND ARCHITECTURAL ASSOCIATIONS.—At the time the Greenock municipal authorities issued invitations to architects for plans for the extensive new municipal buildings, they agreed that the rate of commission to the successful architect should be 4 per cent. on the full cost of the building, the estimate for which was not to exceed £80,000. Upwards of eighty architects at once entered as competitors on the terms proposed; but the Liverpool Architects' Association wrote to the Greenock Town Council complaining of the lowness of the rate of percentage, and stating that it was considered derogatory to a professional man to give his services for less than 5 per cent. for the class of building referred to. At the monthly meeting of the Greenock Town Council, a letter was submitted from the Manchester Architectural Association making the same complaint, stating that they considered that the stipulation of 4 per cent. had a great tendency to lead to questionable practices, to the discredit of architects, and to the disadvantage of their clients. The Council unanimously resolved to adhere to the 4 per cent. commission; and the Provost, referring to the Manchester complaint, said he had not a particle of sympathy with these associations. People were apt to speak harshly against the working men who form trade unions, but this was as complete a trades union as had ever existed amongst working men.

Intercommunication.

QUESTIONS.

[5725].—**Substitute for Mortar.**—Wanted to know the best substitute for lime-and-river-sand mortar, which is often falling off and gets soaked full of wet. Tallow and tar both have been uselessly used on the surface. The walls of the house for which it is wanted are of brick, built 20 years ago. The east end is 46ft. by 44ft., exposed to the weather. The west end has 46ft. by 24ft. exposed to the weather. Of these, which are the best to adopt, or what otherwise? Tile or slate nailed on laths, and common mortar, or Portland cement one part, river sand two parts, in two coats, fluidising with lin. in thickness? Whose cement is to be preferred?—A. S.

[5726].—**Breaking Weight of Girders.**—Could any of your readers kindly give a reliable formula for calculating the breaking weights of the following girders:—1. A girder composed of a rolled joist with a plate on the top. 2. A girder composed of a rolled joist with a plate on the top and a plate on the bottom. 3. A girder composed of two or three rolled joists with plates on top and bottom.—T. W. LEEDS.

[5727].—**Slating.**—I am desirous of using thick green or grey slates of small size, and not smooth surface. Will some one kindly inform me as to cost as compared with tiles south of London, and also briefly describe the slating, stating how laid and upon what?—H. B.

[5728].—**Coloured Building Stone.**—Can any one give information as to Findon stone? There was an agency for it in Southampton-buildings many years ago, which has disappeared. The stone was brought by water up the Thames. I should be glad to hear of any available quarry of yellow, red, or brown walling stone, which could be brought to London by water at moderate cost.—W. W.

[5729].—**Pointing Red Brickwork.**—I am about to have pointed some red-brick faced houses I have just erected. Will some of your readers kindly inform me if Abertaw lime, with a little London cement and fine sand added, are the best materials for such purpose? If not, what are? Also what colour is the pointing of red brick buildings now erected finished in? Also I should be glad to know the joint, &c.—CONSTANT READER.

[5730].—**Softening Putty.**—I have some old sashes glazed with plate glass, and I wish to take it out without breaking. Will someone experienced kindly say the best way of softening the putty of same?—T. P. B.

[5731].—**Concrete Steps.**—What is the proper proportions of cement and gravel to be used for the making of concrete steps? Would some of your readers who have had experience in this kindly give particulars?—O.

[5732].—**Rats.**—Can anyone suggest a means of filling in behind skirtings and stowings in an old country mansion so as to prevent the rats from having free run of the house? Any information as to a successful method of getting rid of these pests will be thankfully received.—G. D. I.

REPLIES.

[5706].—**Labourers' Cottage Fittings.**—In reply to your questions, an ordinary barred grate is certainly as useful as a range for the ordinary class of labourers, but for cottages professing to be built for intelligent occupants a small range is to be preferred. There are numerous ranges, costing about £3, to be obtained at most ironmongers.—G. H.

[5703].—**Stone Floors.**—For stores and warehouses, the best kind of floor (fireproof) would be concrete and iron, the iron being placed either in girders or as ties

only in the lower portion embedded in the concrete. Girders 13 or 14 in. deep, made of two 12 in. rolled joists, with 5 in. flanges, united by flange plates—making box girders, may be placed 10 to 12 ft. apart. Rolled joists, 4 in. deep, may be fixed between at right angles or iron ties, only about 3 in. apart upon and round which network of iron the concrete is filled in. A solid concrete floor may be formed also of simple iron rolled joists placed about 2 ft. apart, embedded in concrete. These floors are better than stone of the kind mentioned. The way to calculate the weight a stone floor will carry is to find out the weight one of the beams will carry safely, or how much of the distributed load over the surface of floor (easily obtained) will rest upon it. This obtained, the number of beams employed will give the total weight per square foot or yard. Of course each beam carries an area of stone between it and the next beam.—G. H.

[5700].—**Perspective.**—"Perspective" begs to thank Mr. Ambrose for his exhaustive description of interior perspective, which, doubtless, will be interesting to many besides the writer. There is only one matter not quite distinct. In cases where the station is out of the centre, and a line of 60° (or 30° on each side) is drawn therefrom to picture plane, where is the limit of vision on the near side, at A or at B? I presume the picture plane must

always be parallel with the eastern wall. If Mr. A. would kindly give us a small diagram it would elucidate the matter fully.—PERSPECTIVE.

[5722].—**Dilapidations.**—There are so many classes of dilapidations that it takes one a considerable time before he is able to answer "straight away," as the Americans have it, a client, who in all probability is a solicitor, on any and every building or repairing question with reference to the liabilities and responsibilities of lessors and lessees, building and adjoining owners, &c., but "Tweedie's" two questions will, I think, be answered as follows:—1. If the covenant to repair be the usual one—i.e., to uphold, maintain, and leave in good condition at the expiration of term, &c.—the lessee is bound not only to repoint defective mortar joints, but also to cut out any defective, rotten, or perished bricks and renew same, and where a wall or chimney shaft is so far out of the perpendicular as to necessitate rebuilding; or, if in London, to bring it under the Metropolitan Building Act, part 2, LXXII., the lessor can compel the lessee to bear the expense of said pulling down and re-erection, except as to part thereof in cases of party structures, as will be found explained in answer No. 2. I have found in settling many dilapidation matters that the age of premises has little or nothing to do with the question (as the lessee in most cases undertakes to keep them in thorough repair) unless they have been in the hands of the same lessee for more than fifty years, and he can show a considerable expenditure for reinstatements, and that is only taken into consideration by the surveyors in settling money claims for dilapidations after the lessee has vacated the premises after notice to repair, without performing the works stipulated in such notice, but it has been ruled that when the lessor stipulates particularly and distinctly the exact amount and quality of the repairs and reinstatements he requires, the lessee is not liable to do anything more to the premises than the specific repairs, &c., alluded to in the notice, and a money claim for dilapidations in such a case would, in my opinion, be barred, should the lessee have performed all the works so set forth previous to giving up possession. 2. The building owner—i.e., the person upon whom notice (under the Metropolitan Building Act, part 2, LXXII.) is served, is bound to conform to it, otherwise the board will take the matter in their own hands and saddle the expense upon him. When, however, the building owner does perform the works specified in said order, he is entitled under the Act within one month from date of completion of same to render to the adjoining owner an account of the cost of such work so far as it refers to any party structure and other portion of premises disturbed through the demolition of the same, and the adjoining owner is liable to the building owner for half the cost of pulling down and re-erection said party structure and any surveyors' expenses in connection therewith, but should the building owner in rebuilding raise such party structure higher than it was formerly, the adjoining owner is only liable for the cost of half that portion of the wall that is necessary for the joint use of both owners, regard being had to the use that each owner makes or did make of such structure. A notice under Metropolitan Building Act, part 2, LXXII., renders the person upon whom it is served liable for the total expense in case of rebuilding party structure (unless he can previously arrange with the adjoining owner) until such time as he renders an account to the adjoining owner—Metropolitan Building Act, part 3, LXXXVIII. 2, and Metropolitan Building Act, part 3, LXXXIX.—but at the same time it frees the building owner from the responsibility of serving the usual three months' party structure notice upon adjoining owner, and all the delays and disagreements that usually follow in its wake.—J. L. SIKWART, Architect.

Mr. W. Johnson, of Newmarket, has been appointed surveyor to that town by the Newmarket Local Board of Health.

WATER SUPPLY AND SANITARY MATTERS.

MERRIOTT.—Lieut.-Col. Ponsonby Cox, Inspector under the Local Government Board, held an inquiry at Merriott, Somersetshire, on Wednesday week relative to a petition by the Chard rural sanitary authority for a provisional order to enable them to take lands by compulsory purchase for the disposal of sewage. It was stated that Mr. Stevenson, an engineer, was employed by the Chard authority to prepare plans for the drainage of the parish, the estimated cost of the work being £2,000. For the drainage of the Lower-street a second set of plans were subsequently prepared by Mr. Brake, of Crewkerne, and the cost of these was estimated at £900. It was proposed to give two sites for the disposal of the sewage, for the outfalls of the higher and lower levels respectively, and the present inquiry was as to obtaining powers to acquire that for the upper district.

SALFORD.—The storage reservoir at Highfield, Salford, which has been in course of construction about eighteen months, is now very nearly completed. The contractor is Mr. C. W. King, of Wigan. The embankment rises 20 feet above the ground level, and is at the base 106 feet thick. Running through each side is a stout puddle wall, and below the ground level a puddle trench 12 feet deep, rendering the embankment at once firm and water-tight. The reservoir is constructed to hold about eight million gallons. The total cost has been upwards of £8,000.

LEGAL.

AN ARCHITECT'S COMMISSION.—At the Hull County Court last week, before Judge Bedwell, Mr. W. P. Burkinshaw, accountant, Hull, brought an action, as trustee under the liquidation of Mr. Bruce, an architect, against Mr. Joseph Ion, 'bns proprietor, to recover the balance of £50, being 2½ per cent. commission upon the estimated cost of certain buildings on the Hesse-road, which Mr. Bruce was engaged to superintend, as architect for the defendant. It was stated on behalf of the plaintiff that in November last the brother of the defendant waited upon Mr. Bruce, and in accordance with his wish, he called upon defendant in the evening. At the interview the defendant said he intended to build some property in Villa-place, Hesse-road, and he would leave his brother, Mr. William Ion, to make arrangements with him (Mr. Bruce). The defendant then went out of the room, and as a result of the conversation he had with the brother, Mr. Bruce measured the ground the following morning, and proceeded with the plans, sections, and elevations. He also prepared tracings of the plans, and took them to the defendant for his approval. Defendant said he had better submit them to the Corporation at once, and witness subsequently sent them in for approval. Mr. Bruce also drew up the form of the application usually sent in such cases, to which defendant signed his name, and the plans were passed in due course. All was ready for tender at the end of December, when Mr. Bruce sent in to the defendant a request for £30 on account. To this he received a letter from the defendant stating that he would pay him for work done, but as he had not decided to have the work done he could not think of paying him. After this defendant was seen personally, and he paid Mr. Bruce £5 on account, and he said that there might be an alteration in the elevation of the shops, as he did not think of building the houses for which a portion of the plans had been prepared. Defendant said he had no objection to pay 5 per cent. commission if the works were carried out, but he had an objection to pay 2½ per cent. if the works were not carried out. Mr. Bruce gave a receipt for the money, and had not received anything since. The defence turned upon the point what had been the instructions given to Mr. Bruce by Mr. Ion, and ultimately the jury returned a verdict for the plaintiff for £11 above the £9 already paid. The Judge granted the usual costs.

LOCAL BOARDS AND PLANS OF NEW ESTATES.—In the matter of the Workington Local Board. High Court of Justice, April 8, Queen's Bench Division. Sittings in Banco, before the Lord Chief Justice and Mr. Justice Mellor. This case raised a question as to the exercise of the power conferred by the Local Government Acts upon local boards of approving or disapproving plans for new buildings or laying out new estates. The Act of 1875, sec. 158, provides that where a plan of work is required by any by-law to be laid before the local authority, the local authority may, within a month, signify in writing, their approval or disapproval of the intended work to the person proposing to execute it; and if the work is commenced, and is not in accordance with the by-law, it may be pulled down and removed. In the present case the applicant had purchased a property in the Workington district, and proposed to lay it out in a certain manner and sent a plan to the Board. After a delay of more than a month, during which there was no approval or disapproval, his solicitor

wrote to them to ascertain whether they approved or disapproved, and upon that the clerk wrote to him to the effect that the Board could not pass the plan at present submitted, but that they were taking steps to enforce the laying down of a street 30ft. in width, in front of Senhouse-place, which would answer the object. Upon this the owner applied to the Board to know in what respects they disapproved, but could obtain no specific reply, and in the result, after a long correspondence, the owner applied to this court for a *mandamus* to the Board to approve or disapprove.—Mr. Waddy, Q.C. (with Mr. Roland), appeared in support of the application. Mr. Cowie appeared for the Board, against it, urging that they had sufficiently disapproved.—Mr. Waddy, on the other side, urged that the Board were bound not merely to say "We disapprove," but to state the grounds of their disapproval, or in what respects they disapproved, as otherwise the owner might be hung up for ever and prevented from dealing with his own land, unless he chose to go on at the risk of having the buildings pulled down by the Board. The object of the enactment evidently was the owner might be called upon to alter his plans in accordance with the views of the Board, and this could not be unless they stated in what respects they disapproved.—The Court observed that the Act did not, in terms, require that the Board should specify in what respects they disapproved.—Mr. Waddy: That is true; but the object of the Act appears to require it, and therefore, it is to be considered as implied, for otherwise the Board might act quite arbitrarily or for some collateral object.—The Lord Chief Justice observed that the Act did not specify on what grounds the Board might disapprove.—Mr. Waddy urged that they were restricted to the grounds specified in the Act, the level of the streets, their construction, and with these proper provision for sewerage, not the position of the streets, as in this instance. They had no right to disapprove on that ground.—The Lord Chief Justice: Then the owner can build?—Mr. Waddy: At the risk of having the buildings pulled down; but he ought not to be put in such a position, and is entitled to know beforehand in what respects the Board disapprove.—The Lord Chief Justice: But you say that they are not entitled to disapprove on this ground—that the street ought to be made elsewhere. Suppose the *mandamus* goes and they return that they disapprove, what remedy would you have? The Act appears to give none in terms.—Mr. Waddy urged that there must by construction be some remedy against an excess of jurisdiction or an excess of arbitrary authority, and there would be a remedy by *mandamus* to approve or disapprove, because in a return the Board must state on what grounds, or in what respects, they disapproved; and if they showed none on which they could legally disapprove it would be bad.—The Lord Chief Justice asked the counsel for the Board whether they were prepared to contend that they could force an owner of land to make his street in another direction from that which he proposed? To which he answered that he did not think he was compelled to go so far as that. Upon that the Court pointed out that the Act specified the matters in respect of which by-laws might be made, and which included the construction and levels of new streets, but not the direction in which they were made. Upon the whole, as the case appeared to raise legal questions of some difficulty and also some difficulty as to the facts, it would be better to grant the rule for a *mandamus*, in order that the questions that arose might be raised on the return. The Lord Chief Justice, however, observed that it was to be hoped that the parties would have the good sense to settle their dispute, as they might easily do. Mr. Justice Mellor quite concurred in that recommendation, observing, "These are expensive amusements."

Tenders are being prepared for Mr. Holloway's New College for Ladies, to be built at Egham. The design is by Mr. W. H. Crossland, and the quantities have been taken off by Mr. C. Batstone, and are unusually elaborate, extending to nearly 1,700 pages, of which some 200 pages are explanatory sketches. The bills of quantities have been lithographed by Messrs. Sprague & Co., 22, Martin's-lane, Cannon-street, E.C. The competition is a limited one, being confined to twelve selected firms.

At the April meeting of the Society of Biblical Archaeology, held on Tuesday, a paper by Mr. E. L. Lushington was read on "The Historical Inscriptions of Seti I. in the Temple at Karnak." The temple was enlarged by this monarch, who reigned B.C. 1455-1404. Owing to the destruction of the upper portion of the walls, many of the historical bas-reliefs are lost; but there still remains a copious record of Seti's victories, beginning on the north side, and relating to the Pharaoh's conquests in the earliest years of his reign.

The foundation-stone of a new Wesleyan chapel was laid on Friday. Mr. W. Botterill, of Hull, is the architect, and the cost will be £670.

Our Office Table.

THE present state of the home timber market, according to the *Timber Trades Journal*, is far from satisfactory. Those who sold early in the season had to submit to considerable sacrifices, and many of the lots were "bought in" in order to try them again later on. The trade is now even more depressed than it was then, and prices are not likely to advance this season. Good lots of clean ash are still in demand, and oak of large size and first quality can be disposed of at fair prices, but inferior descriptions of timber are almost unsaleable, and in many cases are converted into fuel. In some of the southern counties the timber which was cut and sold two years ago is not yet cleared out of the plantations. This is clearly locking up capital in a ruinous manner, as there is not only a charge of interest annually accumulating, but the timber itself is depreciating in value from exposure to the changes of a variable climate. It would be wrong to assume that these losses fall entirely, or even mainly, upon the purchaser. He occasionally makes a bad bargain, but in times of dull trade the loss falls principally upon the vendor. At a sale of timber a few months ago where the lots were all carefully measured and valued by a competent forester, his valuation was so much in excess of the highest prices offered at the sale that most of the lots were bought in. Since then at several sales where this precaution has not been adopted, some of the lots sold at prices which left a very large margin for locked-up capital and other contingencies. The only two descriptions of timber the writer has never experienced any difficulty in selling are larch and ash. These are saleable at remunerative prices in almost every corner of Britain. No other timber trees will realise such handsome profits in a given number of years; it is strange that ash as an independent crop is not more frequently planted.

THE last but one of the Mayfair Drawing Room series of lectures was delivered by Mr. Ernest Turner, F.R.I.B.A., on Thursday week, in the presence of H.R.H. the Princess Mary of Cambridge and a fashionable audience. The lecturer treated the subject, "The Ideal Dwelling-house," from a hygienic point of view, and gave many examples, illustrated by diagrams, of sanitary defects too commonly found. A point of much interest was a description of a method of ascertaining, without taking up the flooring, whether drains under houses were leaky. The simplest method of excluding sewer air from dwelling-houses without recourse to expensive patents was also described. After calling attention to statistics proving the importance of the subject, and its bearing upon the well-being of the community, practical suggestions were made with regard to the improvement of the drainage, water supply, warming and lighting of existing houses. Referring to ventilation, numerous means were constantly being introduced for admitting cold air, but the admission of warm fresh air was too much neglected, and the advantages to be derived from ventilating grates were forcibly pointed out. A simple method of preventing water from freezing in cisterns, by means of a branch from the expansion pipe of the hot-water cistern, was shown. The dangers to health arising from dust-bins were alluded to, and the system, or rather want of system, of collecting dust in London, was strongly condemned. Mr. Turner insisted that the most rational and economical means was house to house collection, and commented on the improper construction of dust-bins, their unnecessary size, and the unsuitability of the materials used in their construction. Householders were much to blame, as much vegetable and other refuse that ought to be dried and burnt was thrown into the dust-bin. The National Health Society propose organising a series of lectures to working plumbers. Suggestions should be sent to the Secretary, 41, Berners-street, London, W.

At a meeting of the Society of Engineers, held on April 7, a paper was read by Mr. Charles E. Hall, on "Modern Machinery for Preparing Macadam for Roads." After introducing the subject generally, the author proceeded to describe the various machines in use in some of the leading quarries and other works in the United Kingdom. The machines were illustrated by diagrams, and in describing them the author commenced with the original Blake Stone Breaker, which was intro-

duced into this country in 1862, and he followed the successive developments down to the present year. The author confined himself to those machines which had been practically successful, and which include Blake's improved, Archer's original, Orland Maddison's, Smith and Roberts', Maddison's, Marsden's, Archer's latest, Hope's, and Hall's "Multiple Action" Machines. The points of excellence and difference were explained by the author, who defined the requirements of a machine necessary for the production of perfectly cubical machine-broken stone for road purposes. Particular attention was called to the importance of dealing with stone in large quantities by an improved disposition of the various machines, in order to secure a better form of metal, with less waste than as usual under the ordinary working conditions, and reference was made to those works where the plan had been more or less closely followed. The development of various expedients for cubing the stone was noticed, and the results (so far as they could be arrived at) given of the working of each. The author stated that he was unable to fix definitely the cost of producing macadam by machinery, which should be true in all cases, as circumstances tended very greatly to modify it. He found from authentic sources that the cost ranged from 25 to 100 per cent. in favour of machine-broken as against hand-broken macadam.

MISS ELIZA METEYARD, author of "Life of Wedgwood," and many other works, died at her residence in Lambeth on Friday last. She was the only daughter of Mr. Meteyard, a surgeon, of Shrewsbury, and she was born early in the present century. Her first work was published in 1845. Miss Meteyard contributed a leading article to the first number of Douglas Jerrold's newspaper, and Jerrold himself appended to that article the signature of "Silverpen," under which *nom de plume* Miss Meteyard contributed extensively to several Metropolitan newspapers and magazines. Miss Meteyard's *magnum opus* was undoubtedly her "Life of Josiah Wedgwood," in which she embodied the results of many years' intelligent and painstaking research, carried on with an absorbing enthusiasm for all that related to the great potter. Her literary labours were recognised by Mr. Gladstone, upon whose advice she was awarded a pension of £60, which was after increased to £100 per annum. Dean Stanley also, in a manner worthy of himself, placed at her disposal the cottage in which she has resided for the last two years.

A COMMITTEE has been formed for the erection of a memorial statue to William Tyndale on the Thames Embankment in London, where a site has been granted by the Metropolitan Board of Works. The committee for this memorial proposes to raise the money in all parts of the British Isles. The total expense will be from £3,000 to £4,000. As it is wished to spread the interest of the scheme over as wide an area as possible, contributions of any amount will be welcomed. The Archbishop of Canterbury, the Lord Chancellor, the Earl of Shaftesbury, the Duke of Westminster, and others, have joined the general committee. An executive committee has been formed to conduct the work, and the Hon. and Rev. W. H. Fremantle, Rector of St. Mary's, Bryanston-square, and Mr. John MacGregor will act as honorary secretaries. The bankers are Messrs. Glyn, Mills, Currie & Co., 67, Lombard-street, E.C. We trust the result may be something more worthy of the site and subject than we have obtained hitherto.

A NEW method of copying drawings, which is said to be useful when a couple of dozen copies or so are wanted, has been brought out in Paris. The apparatus consists of a shallow zinc tray, in which is contained a smooth, jelly-like, cream-coloured substance, resembling in some degree partially solidified flour-paste. The drawing to be copied is made with a special ink. As soon as it is dry it is turned face downwards on the contents of the tray. The back of the drawing is then rubbed over with the hand. The sheet is then lifted up, leaving much of the ink transferred to the substance in the tray. A sheet of clean paper now takes the place of the drawing, and by rubbing it over gently with the hand, an accurate copy of the original is obtained. With care, as many as 100 copies can be had. When all that are needed have been taken, the composition in the tray is washed with a damp sponge, and is then ready for use again. The nature of the composition has not been made public.

With the sanction of the trustees of the British Museum, and under the auspices of the Society of Biblical Archaeology, Mr. Stephen Thompson, who has lately returned from a professional expedition to Cyprus, is about to reproduce the bronze ornaments of the palace gates from Balawat, near Nimroud, in the exact size and colour of the originals, by means of the autotype permanent process. It is proposed to issue with the *fac-simile* plates letterpress descriptions by Mr. T. G. Pinches, the whole work of reproduction being under the superintendence of Dr. S. Birch, keeper of the Oriental Department of the British Museum. The entire publication will consist of about 90 large plates.

THE Spring Exhibition of Water Colours by living artists, at the Royal Pavilion Gallery, Brighton, opens to-day, and contains several pictures by well-known and local artists. We observe the names of A. MacCallum, A. F. Grace, Edwin Hayes, A. W. Bayes, D. Law, Harry Hine, Clem Lambert, R. H. Nibbs, O. B. Lomax, R. Cooper, Jules Lessore, Barraud, Bayliss, W. Cruickshank, B. E. Ward, P. F. Poole, R.A., R. Meyerheim, Spiers, Mearthur, G. L. Beetholme, Haylar, Cox, and several others, many of whose works have on previous occasions enriched the walls. Landscape, still life and fruit, form the staple subjects of the present exhibition. Coast scenery in Devonshire, Cornwall, Sussex, &c., appears to present a never-failing source for the artist's pencil. Thus we have some studies near Hastings by R. Beavis, Clara Montalba, and Charles Collins; sketches of the South Coast, &c. Shoreham seems a favoured place for artists of scenery of this kind, and the Harbour is a favourite theme. Bramber, Hurstpierpoint, East Grinstead, are all capital places for the study of colour and picturesque effects. We notice several architectural sketches, among them "Long Parish Church, Hants," by O'Brien Lomax; "Rochester Cathedral," by G. de Paris; "Near Arundel," by W. H. Mason; "View of Chichester Cathedral," by Clara H. Warne; "Church Porch, South Hayling," by E. Evans; "Bridge-street, Chester," by A. B. Donaldson; "Grand Canal, Venice," by J. Lessore; "St. Mark's, Venice," by the same; "Kenilworth Castle," by C. Marshall; "A Roman Triumphal Arch," by J. M. Donne; "Capella di Santa Fina St. Gemigneani," by M. S. Wratlaw; also Nos. 94, 102, 115, 339, 566, 593, 546, 507, 356, 215, 520, and last, though not least, Mr. W. Bayliss's "The Lily of France—La Sainte Chapelle."

NOUMEITE is a stone of much beauty, capable of being used for many of the ornamental purposes to which malachite, serpentine, and verd-antique are applied. It does not possess sufficient homogeneity to entitle it to the name of mineral, and although it contains a heavy metal and can be employed for its preparation, the name of ore does not sufficiently describe it; neither can we properly call it a rock, as its constituents are too few and familiar. Briefly described, it is a massive form of *garnierite*, or hydrated silicate of nickel and magnesia. It comes from New Caledonia, and was discovered

a few years since by F. Garnier, whence the later name. The former name *noumeite* is derived from that of the principal town of New Caledonia, Noumea, which has since been changed, however, to Port de France. At the recent World's Fair in Paris this substance was exhibited in large quantities, and we learn that it has already become an article of great importance to the nickel industry of France.

THE REV. CHARLES H. MIDDLETON has replied in pamphlet form (Spottiswoode and Co. publishers) to a letter published by Mr. F. Seymour Haden, F.R.C.S., under the title of "The Etched Work of Rembrandt." Mr. Haden charged Mr. Middleton with having appropriated his views and his chronological arrangement, and declared that, apart from those appropriations, Mr. Middleton's publications are worthless. In this reply Mr. Middleton repudiates the accusations in vigorous terms as unjust and untrue. He explains the footing upon which he became a member of the Burlington Fine Arts Club, to the members of which the "Reply" is primarily addressed, shows the origin and character of his work in connection with the proposed Rembrandt Exhibition at the Club, and quotes passages from letters addressed to a contemporary, referring to their dates as establishing his innocence of the charge of plagiarism. No point of permanent importance to the outside public is debated. The controversy is indeed essentially a personal one, and seems to be conducted on either side with an acerbity and warmth of feeling which may give piquancy to the discussion to those who have followed its details, but will impart to it little interest to the uninitiated in cataloguing intricacies and amenities.

SERIOUS damage has happened to the dock at the port of Silloth, on the Cumberland coast of the Solway. About four o'clock on Sunday afternoon the wall on the west side of the entrance to the dock gave way. One of the dock gates fell, and the water, which at the time was standing about 21ft. deep in the dock, rushed out with great force, carrying away about 20 yards of the west pierhead, which, having been stripped of its protecting masonry, offered but little resistance to the current. The west gate, in its fall, knocked the east gate out of its proper position, but it is still standing in a dilapidated state, and the wall on the east side of the entrance appears to be in a somewhat critical condition. The large blocks of masonry of which the west wall was composed having fallen into the entrance to the dock, a complete stop has been placed upon navigation. The cause of the disaster has not yet been definitely ascertained, but the general surmise is that the sill of the dock, owing to some gradually increasing defect, had burst up, and the water thus gaining access to the foundation of the wall got behind it, and bulged it in. It will cost between £20,000 and £30,000 to repair the damage.

Lamplough's Pyretic Saline is refreshing, most agreeable, and the preventive of FEVER, BILIOUSNESS, SMALL-POX, SKIN DISEASES, and many other spring and summer ailments. Sold by chemists throughout the world, and the Maker, 113, Holborn Hill. Use no substitute.—[ADVT.]

CHUBB'S

WROUGHT IRON DOORS,

Fire and Thief-Resisting Strong Rooms, Safes, and Iron Linings.

THREE PRIZE MEDALS

And Honourable Mention at PARIS EXHIBITION, 1878. Illustrated Price Lists post-free.

CHUBB & SON, Makers to the Bank of England, 125, Queen Victoria-street, St. Paul's, E.C.; and 68, St. James's-street, Pall Mall, London.—[ADVT.]

CHIPS.

The restoration of Bexhill Church, Sussex, is progressing rapidly. The church has been cleared of old fittings, which are to be replaced by open benches and other suitable furniture; the walls are being repainted and replastered, and the roofs entirely retiled, while the tower is being partially rebuilt.

Mr. John Pagan, C.E., who has for the past four years been Borough Surveyor of Wakefield, has been appointed Colonial Surveyor and head of the Public Works Department in the Colony of the Gold Coast, at a salary of £800 a year.

At a special meeting of the trustees of the Lower Ouse (Sussex) Navigation, held at Lewes, on Monday, it was decided to erect a new iron bridge over the river at Southease, in accordance with plans submitted by the engineer, Mr. Wallis, of Westminster. The cost is not to exceed the estimate of £2,252 17s., the actual tender of a firm in Staffordshire, and the bridge is to bear the weight of traction engines up to 20 tons.

The corporation of the decayed Cinque Port of Pevensy have instructed the town surveyor to stake out land, preparatory to entering upon a building scheme, in the hamlet of Wallsend, which it is hoped will be ultimately joined by roads and houses to Eastbourne.

A new steam laundry has been opened at Dorchester. The buildings have been constructed from the designs of Mr. Gregory, of that town.

New offices for the Guardians of the Portsea Island Union are about to be erected at Portsmouth, at an outlay of £5,575.

Mr. W. Logsdail, of Lincoln, has carried off the first prize in the School of Fine Arts at Antwerp, the leading academy for painters in Europe. The school is frequented by many English students, but the prize, it is stated, has never before been carried off by an Englishman.

A Methodist New Connexion chapel, at Bistre, North Wales, is approaching completion. Mr. R. Owen, of Breck-road, Liverpool, is the architect, and Mr. John Williams, of Buckley, the contractor. The chapel will seat 300 people.

A stained-glass window has been placed in the east end of the north aisle of Blofield Church, Norfolk. The window is of the Perpendicular period, and of three lights; these are filled with life-size figures of the Saviour, Moses, and Elias. The tracery is filled with angels playing musical instruments, including the harp, organ, violin, trumpet, &c. The work was executed by Messrs. J. and J. King, of Norwich.

At the meeting of the restoration committee for the Church of St. Peter Mancroft, Norwich, it was unanimously agreed to consult Mr. George Edmund Street, R.A., as architect, and to request him to report as to the extent of restoration necessary, and what portions of the fabric require immediate attention.

CHAPPUIS' PATENTS

FOR

REFLECTING LIGHT.—DAYLIGHT REFLECTORS

OF EVERY DESCRIPTION, ALSO

ARTIFICIAL LIGHT REFLECTORS.

P. E. CHAPPUIS, Patentee. Factory, 69, Fleet-street, London, E.C.

N.B.—DIAGRAMS AND PROSPECTUSES ON APPLICATION.

THE BUILDING NEWS.

LONDON, FRIDAY, APRIL 18, 1879.

THE FINE ARTS AND OPTICS.

THE relations between these arts and this science, and of this science, indeed, with architecture also, are not sufficiently studied. Nothing, however, can be more obvious than the influence of light and vision upon all objects whatever, natural or artificial. That which, in semi-darkness, is only a sketch, becomes in full day a distinct outline; and, of course, not tints and shadows merely, but colour in its every variation, depend absolutely upon the medium through which they are viewed. Dimensions, form, and so forth are acted upon greatly through this element, which largely accounts, therefore, for the effect of different architectural styles in different climates. The study of light, indeed, is essential to much of human knowledge—to astronomy and mathematics, for example—but in no realm is it more essential than in association with the Arts, and painting especially. The two, in fact, are kindred, or rather the one owes its birth to the other. It is this which produces foregrounds, middle-distances, and backgrounds, solid and aerial perspectives, gradations of hue in landscape, modulations of beauty in the human form; it governs the blending of pigments and the distribution of shadows, and yet no two vocations are more opposite, more widely sundered, more in contrast, as pure mechanics must be in comparison with pure fancy, than those of the artist and the optician. But the results of their studies are in a considerable degree the same—that is, when due thought is thrown into either, although it has been frequently the case that an artist has produced effects of light which have perplexed an optician, while an optician has laid down laws of light unintelligible to an artist—the one, as it were, speaking poetry, and the other algebra; the first creating harmony out of an unknown law, the second constructing a law out of an unappreciated harmony. We have to do with the former rather than with the latter. When Raffaele painted "The Holy Family," Correggio the "Marriage of Saint Katherine," and Murillo his Virgins surrounded by angels, and enveloped in a mystical radiance, these men were engaged upon works of science scarcely less than of art; they brought its realities to the aid of their imagination, and a similar remark applies to the canvases of all the painters who were poets, without being imitators, and who worked at their best, whether it was Sanzio in the porch of a Roman temple, or Drolling in a Dutch kitchen. Granet used to close his shutters at noon, and labour by the illumination of an oil lamp; and "single-candle" Schenckel's name is a by-word in the studios of Europe. Those Low Country artists, indeed, often subordinated everything, the human figure itself included, to the producing of variation in light and shade. For this they degraded their subjects; for this they introduced every species of eccentricity; they preferred a sun's ray, falling through a barn-door on a heap of yellow corn, to an Italian glimpse of blue sky and golden-winged angels. Where should we be (was an old question among artists) if the distribution and power of light were equal everywhere? There would certainly be no Italian, and there would be no Flemish schools, for Venice and Naples are not less necessary to the one than Amsterdam and the Zuyder Zee are to the other. The element—to call it one—is not only poured

upon almost every object in nature; it is reflected from and refracted by it; and every hill and tree, house and rock, man or animal, possesses an individual illumination. Thus, the Germans. But it is not requisite to accept all their abstractions on the subject. The simplest ab-initial knowledge tells us that, without light, coal would not be black, the sky blue, a rose red, or a diamond sparkling. These are the earliest teachings of optics; and when art takes up the tale, it is at the point where lights and shadows, colours and dead surfaces, have to be adapted or combined, contrasted or compared. The Greek painters, of whose works so few are left, knew that the strongest glow of yellow, blue, or green, thrown upon a deep red, would darken instead of lightening it; they never, therefore, put these colours into juxtaposition; they challenged crimson with white, and found it unconquerable; but when they threw upon either a flood of perfect, untinted light, coming, whether artificial or not, from the natural direction of the sun, they never found the experiment to fail. In later days, Newton, conversing with an artist, spoke of their discrimination as of an instinct. But, although the artist, in search of a medium through which to paint, may elect between the humid verdure of Ireland, the mist-crowned Scottish mountains, the transparencies of the English Lake atmosphere, or the thousand-and-one illusions of air and colour on the Continent, in America, or in the East, he must expect endless fluctuations, from hour to hour, from moment to moment, even on one and the same spot. No landscape is ever the same for an instant together. Photography can do nothing with nature. It may outline a form, human or other, or a ruin, or an horizon; it can suggest where the lights and the shadows lie, but what shadows and what lights it cannot tell, while, with reference to the beauty of a rainbow, or a sunset, a sea, a flower, or an altar-piece, it is dumb altogether. It can no more represent these than it can emulate the human eye.

It is a well-acknowledged fact that pictures change according to the light in which they are looked at. There is a subtle, and yet an easily distinguishable difference between them when viewed with the assistance of gas or lamps, and in the open air. The medium, even of a gallery at noon, is not exactly like that, for instance of a garden terrace, at the same hour. And the painter's work itself varies in an equal degree under the varying influences of the lights and shades to which his palette and easel are exposed. It is not difficult to understand, then, the characteristics of canvases such as those of Salvator Rosa and Rembrandt, of Van Huysum and Wouvermans, of Claude Lorraine and Canaletti. One glance at, one remembrance of their works, will suggest how much they were indebted to, how much they were governed by, their climate—which is only another word for the light in which they laboured. It would have been as impossible for Claude to paint his visionary paradise among the swamps of Holland, as for Greuze to have found his ideals in a Hindoo zenana. Slave as he is, therefore, of the light, the artist rarely pauses to reflect what may be the effect upon the eye, in England, of a picture painted, say, at Florence or Rome, at Munich, or in Calcutta. Nevertheless, it is sure to be materially different from that which he intends, and a surprise, perhaps, even to himself. He cannot carry with him the atmosphere of his studio, and this, perhaps, it was which induced sundry of the old masters to paint invariably by lamp-light. This enabled them, they said, to soften all their tints and shades, to paint independently of climate, and to level down their surfaces, so to speak, so that they might be violently inharmonious nowhere.

But these men did not derive their ideas from their darkened studios; they had seen Nature, of whatever kind, abroad, and the sun and the sky and the bloom of the earth were in their eyes, no matter whether or not they had drawn their curtains before sitting down, palette and brush in hand. The artist, then, who works on any noble scale, seeks, with the sole assistance of his eye, representing his mind, to distribute lights and shadows, in proportionate masses on his canvas, striving to preserve their due relations, and to keep them in harmony with whatever groups or figures may constitute the living interest of his picture—the details, matters in themselves, which are to be paramount above the whole. The optician studies also these grand effects; but he can bring machinery to his aid; he can multiply his own natural powers; he can measure, and even weigh, the light he wants to use; he employs, in fact, an apparatus which, in these and latter days, physicians have found inevitable, and which, in time to come, perhaps artists may not despise. The Photometre, indeed, has already found its way into some of the German studios; but many painters fear lest its application should conduce to a system of mechanical accuracy in art, entirely incompatible with the free range of invention and fancy. It is like, they say, compelling Nature to pose through an opera-glass. Undoubtedly, such a medium is apt to throw up false lights and false shadows equally, of whatever shape and colour the object may be, yellow or blue, a house, a cart, or a garden wall. Then, is an artist to copy, without calculating, or is he to summon to his assistance, a more than a pre-Raphaelite—a scientific precision, as to matters of fact? For that is really the question. A French critic has put it to the test. He brought his apparatus near to where an artist sat, painting a yellow wall; he fixed his photometer so as to take in the object; after the work was done he fixed it in like manner upon the picture. The result was, he says, the triumph of a test which few pictures could undergo, with the discomfiture of the painter. Two errors, we are assured on the same authority, interfere with the proper concentration and dispersion of light on canvas, the one a timidity in the deepening of shadows, the other a too great freedom in the employment of pure yellows, and when these have to be modified the more sombre ochres, often bastardised by other and, in themselves, corrupted pigments. With these, of course, light can never be equal, or the tone harmonious, though the colour produced may appear fascinating enough at a superficial glance; but in these instances—and here is a profound mistake which the great old masters never committed—the light is not consonant with the shadow; in other words, the artist was not possessed of the optical science or instinct. For in every work of fine art the lights and the shadows, analysed, will be found consistent, and the one belonging naturally to the other. The same ray from the sun, penetrating the same medium, produces both, and a summer shadow in Rome is no more like a winter shadow in St. Petersburg than the leaning tower of Pisa is like the porcelain tower of Pekin. Modern landscape painters, it is true, have observed upon this fact, and endeavoured to profit by it. Decamps, for example, is geometrically exact in his distribution of the sun's rays at particular hours of the day, and even in different latitudes. What, it may be asked, is the influence of this exactitude upon the mere connoisseur? It creates a sense of the real, it tends towards an education in art; in fact, the farther we leave the ordinary pastures of home and approach the East—Egypt, for instance—it becomes an essential. An Egyptian landscape is all colour and light, so is an Egyptian ruin; a sunless Cairo would be, on canvas, the merest heap of dilapi-

dation. Moreover, painters of night scenes have felt the difficulty in its full force. Generally, like that marvellous Schenel of whom mention has been made, they place a flaring lamp in the middle of their canvas; they surround it with an obscure interior, or the confusion of a crowded market-place; they either throw its beams upon common objects, intensely illuminated, or lose them among the shadows beyond. M. Jules Janin, analysing these effects, found that the lamp in the picture gave forth fourteen out of fifteen times less than the light that was actually due from it. This, of course, was an arbitrary conclusion, derived from, as it were, an imaginative experiment, but it brought Science, in a way, to the door of Art, and the two did not agree. Granet, already spoken of, was a master of the art of illusion produced by these mere contrasts of darkness and light. "M. Granet," said the Eighteenth Louis, "I am always afraid to look at one of your Capuchins taking snuff, lest he should sneeze in my face"; a profound compliment to the artist, but an utter repudiation of colour; for these pictures were all of vaulted, cloistered halls, subterranean passages, grated windows, and sombre staircases, with a single beam of light, and no more, introduced somewhere. The truthfulness of this artist, therefore, says his critic, is not less an illusion than the illusion he was so fond of attempting to produce. More than this, however. The precision aimed at by these elaborate methods is often not obtained. A sky full of clouds will appear sometimes of a dead white when scanned by means of the photometer; a false dazzle, too, is occasionally created, even by the most perfectly-adjusted instruments, and the finest judge, the most infallible reflector is, after all, notwithstanding its eccentricities, the human eye, than which, assuredly, no mechanical optical arrangements can be better adapted to compass whatever there is of colour or outline in art or nature. The reproduction of colour, as already said, is beyond the reach or hope of any mechanism, and, as to outline, the more largely it is extended, by whatever copyist machine may be employed, the more it becomes blurred and indistinct. Art has been made, in its inferior degrees, very much an affair of optics in recent years; but optics, as applied to the higher and finer arts, appear to have been scarcely worth a thought.

THE IPSWICH POST-OFFICE COMPETITION.

THE Ipswich Corn Exchange is to give place to a new Post-office, combined with Corporation offices, and the provision of a new Corn Exchange is contemplated by the extension of the public hall in Westgate-street, while designs for a school of art and museum have just been invited. Twenty-two designs have been sent in for the first-mentioned project, now on view at the Town-hall. The Corporation in their printed instructions imposed certain conditions as to plan and style, which really left competing architects little or no liberty, and the result is a set of drawings that display an unusual want of originality or invention. The site of the present Corn Exchange was given, and as the area was confined by the existing walls of that building there was no opportunity for artistic skill in the grouping of parts, or play breaks or recessions in the line of the façades which an architect is naturally prone to indulge in. Furthermore, the competitors were bound to a certain internal arrangement for the Post-office prepared by the borough surveyor, who also suggested a scheme of subdivision for the public offices, and, in short, they had simply the task before them of supplying a set of façades in a given style for the four front-

ages. The town-hall adjoining the site, but separated by King-street, a by-no-means unimportant structure, in a freely treated species of Italian, moreover supplied the keynote for the composition of the new building, which was required to be "Classic." A set feature, or rather cast of expression, was given by another suggestion that a portico entrance of certain projection should be shown on the chief or Cornhill front. It would be expecting too much under these restrictions to look for any great amount of architectural skill, much less of variety, in the treatment, and we have accordingly a set of designs ranging from Classic models to free Italian or Renaissance. In the larger number of designs, the model plan as regards the distribution of the windows has been scrupulously adhered to, notwithstanding considerable architectural variety would have been attained by a free redivision of them. The value of pronouncing the public offices towards King-street especially has been neglected in some cases; while the canted corners shown in the regulation plan, always very difficult problem in Classic design, have not, except in one or two instances, been cleverly managed. We may here suggest another departure from the plan that would be a great public convenience. Most of the designs show the postal boxes below the portico reached by a flight of steps, the inconvenience of which might have been avoided by utilising a part of the public office near the King-street angle for the receptacles, and by introducing boxes below or in the window-openings, as observed in many of the metropolitan post-offices. An easier and readier mode of communication between the public and sorting offices might have thus been effected.

Proceeding to notice the designs in detail, we commence with "Well Considered," because we understand it has been favourably entertained by the committee. In plan we notice little or no departure from the model scheme. The floor of the Post-Office is raised about 3ft. above the Cornhill level, and the façade facing this open space is adorned by a rusticated basement, a portico of coupled columns, and with pilasters between windows above. These have semicircular heads filled with sculptured tympana, while the pedestals above the portico have groups of sculpture, representing the Arts and Sciences, certainly an unnecessary and costly addition, scarcely appropriate to the building, though not included in the author's estimate. The angle windows do not rank agreeably with those of the façade and flank, and their omission or reduction in width would have been an improvement. The clock-pediment over the centre, and the terminals are useless, and certainly unmeaning features. In the return façade towards King-street, the public offices are pronounced by a pediment. The style chosen is Classic of a Greco-Roman type, broadly treated in parts, and the design is illustrated by a bold pencil perspective.

"Dum Spiro Spero," shown by an ink perspective, is designed in a more commonplace type of Italian; it has pilasters at angles, the centre ordnance over Ionic portico is carried through the pediment in a not very elegant manner. As in many other cases, the author proposes stone from Bradford for the principal front, combined with white Suffolk bricks. As a Classical composition, "Mercury" ranks high in merit. In the perspective drawing we recognise a well-known hand. The Cornhill front is in a broad astylar treatment, Florentine in feeling, without a pediment, a bold modillion cornice of some projection crowning the building, and a low wide portico of Roman Doric, with coupled columns before the entrance. The angles are left canted, but the windows in them, unlike those in "Well Considered," are narrow. The lines and

fenestration of the façades are almost academic in severity, but elegant; the architrave mouldings continue to the cornice, and enclose above the heads of windows some carved relief. Steps between the pedestals of the columns give access to the portico, but here, as in most instances, the necessities of a public post-office have been lost sight of. The building is conceived too much in a villa or club-house style, and whatever merit it has in the chief façade is sacrificed to the exceedingly meagre and common-place treatment of the façades facing the Town Hall and old Herb Market. Nothing could be more pinched or starved in effect than these fronts, and the author appears to have lost all interest in his design immediately he turned the corner, in spite of the fact that the King-street front will be seen quite as much as the Cornhill façade. The Corporation offices are separated by a slight recess in the wall at the corridor entrance. The materials proposed are ashlar, or white brick facings. We note rather useless accessories in the shape of sculptured arms above the angle windows. The author's estimate is £6,081.

"Effect and Economy" is a large pencil perspective in a free Italian dress, with portico and pedimented treatment of front, over a rusticated basement. The upper story is enriched by panelled pilasters and pedimental-headed windows, in a style that rather competes with the town hall, and economy does not appear to be the leading recommendation. In the return front the public offices are not well managed, the horizontal members and string-courses being cut through by the lower windows. In the plan the author shows a few deviations; the school board-room, 20ft. 6in. by 25ft. 6in., is not placed in the centre, but at the King-street end of the range of offices, and on the second floor the principal office is above it. We think this an improvement. In the space in centre of basement, under post-office, the author suggests that 8 strong-rooms should be erected for the use of the public offices, and for letting.

"V. R." is a striking design illustrated by a large ink perspective drawing. The style is Italian freely treated, with pilasters. There is a Doric portico, the public offices being emphasised by a different treatment of windows, and a break in the lines of composition over the public offices entrance. A level roof as in most other cases is shown. The stairs are altered from the centre of public offices, as in the Corporation's plan, to the end of corridor, which is a better position. The figure of Britannia on the façade would have been wisely omitted, and if instead of a clock over the portico, common to many designs, an anemometer were substituted, an instrument of some utility would be added to the town, while a clock might be placed in the King-street angle of the building, and it is surprising this better seen position has not been selected. The canted corner by the way offered a capital position for a clock, which might have been placed between the stories or at the summit under a pediment. Being in the instrument room, the position would be a desirable one.

A design noticed with some favour by local critics is "Sivez Moi." The author's design, though rich, is not redundant in pilasters or carving. A breadth of effect is obtained, and if it lacks anything it is in refinement of detail. The style is Italian, broken in the cornices with circular corners, and angle pilasters. There is a centre panel with Royal arms over the façade. We dislike the iron cresting to roof—a rather vulgar source of effect. The author, sensible of the lowliness of the sum to be expended, estimates the Post-office at £4,194, and the Corporation offices at £2,369, the cubic contents of the former being calculated at 167,758ft. The author, in not very good taste, puts in a plea for acceptance on the ground of his

being a native of Suffolk, and having received his education in Ipswich. Such a practice is to be reprehended in competition as unfair to others. In the design "Despatch" (in red), which is, we believe, by a local architect, we are struck by a simplicity of treatment in spite of the obvious violation of some conventional proprieties of the style. The drawings are feelingly rendered in a style that may be called Palladian, though inexpensive in the material proposed, and not lavish in carving. We might find fault with the rather purposeless pilasters between windows and some other inaccuracies of composition. The offices are unemphasised. In an amended plan, the author shows the sorting-office along the King-street front, the sorting-table by this means communicating with the letter-box; and the doors, area, three w.c.'s, are shifted a little in position. A stone basement, with white Suffolk facings above, are proposed. Very unlike, and in rather "grandiose" Italian, is an elaborate set of drawings with a Postage-Stamp for motto. The style is Italian or Roman of one order, with pilasters at the angles in pairs, a pediment over portico, the latter arched between the piers. Pediments are placed in the centre of each front, and no difference of treatment is attempted in the offices portion. The elevations are carefully drawn. Our previous remarks upon the position of a clock in the main façade apply to this design. White bricks are proposed for the back elevations, with stone ashlar for the Cornhill front. The style adopted is expensive and rather ambitious, and the building is seriously estimated to cost £5,950; another thousand would be nearer the mark. "Civis Non Peregrinus" sends three designs: the first, shown by a neat perspective, is the best, and is conceived in an Italian spirit. The old portico is retained and carried up to the top of the building by another superimposed order, crowned by a pediment, a plan that certainly gives solidity and dignity, if it is a costly feature. The angle pilasters do not break at the angles. We like less the design marked "B," where the pilasters are placed in a wrong position, and the details are poor; a third, "C," is crowned by a heavy pedimental tablet with the inscription "Post-office," perhaps quite as desirable as a clock in a town like Ipswich, frequented by strangers. The parapets are undesirable features, and are certainly costly and troublesome. The author cubes his building at 140,350ft. for post-office, and at 94,000ft. for the municipal offices, making a total of £6,056.

A few other designs call for notice, though of less merit than the above. "Harmony," half-shaded in colour, is an Italian composition, with pediments on each front, a circular arched portico, rounded corners, and commonplace detail. The estimated cost is £7,000; "Animo et Fide" is tawdry in treatment, and redundant with worn-out and expensive features, such as a domical hip roof and a cupola. On the whole, it looks like a miniature copy of the Town Hall. "Despatch," which we distinguish as No. 2, shows a rather weak composition, particularly at the sides; the window pediments are costly features, and would necessitate stone. The elevations in outline are not accompanied, apparently, by any other drawings. "Ipswich Arms" is hard and meagre. "Post Officia Fortuna" shows a pediment brought out over the portico with pedimented corners. "Faith" is grotesque, and crowned by a cupola, deeply undercut at the base, and toy-like in character. "Corona" is an olla podrida of Italian. "Courage" lacks the public character, while "Red Star" is an exceedingly ponderous design, with excessively heavy corbelled window heads, and no relief whatever.

On the whole, it must be confessed that there is no one design that can be carried out effectively for the sum intended to be

spent, and we may add our opinion that a sum of £6,000 is totally inadequate for the erection of a building of the dimensions required, and in a style worthy of association with the Town Hall. As it is, we find the estimates vary from £5,600 to £13,000; while, if we examine the cubing, we note an unaccountable and astonishing difference made for a building of predetermined dimensions, the figures ranging from 200,000 to 400,000 cubic feet. We have roughly cubed the two portions of the building, and find the cubing of both come to about 300,000ft., or a trifle less. The rate per foot cube also exhibits an equal disparity, some competitors pricing at 6d. and others at 9d., the average appearing to be 6½d. for the municipal offices, and 7½d. for the Post-office. Judging from the character of the designs, many of them must have been cubed at even a less figure than 6d., if the matter was considered at all, which is certainly doubtful. Under such circumstances, we strongly recommend the Corporation to obtain professional advice, as regards cost, at least, before coming to a final decision. In regard to the style, something essentially plainer and of greater solidity of character than the Town Hall is required. There should be nothing in the post-office front to suggest comparison, or compete with the more important municipal structure by the side of it—nothing exaggerated, pretentious, or grotesque in feature or style. The Cornhill front ought undoubtedly to have a portico of spacious width, such as many of the designs show, of Classical proportions, quiet, and very moderate in enrichment; the façade should be united to the portico by the dominant lines of cornice or entablature, and the whole front should be symmetrical and balanced, deriving its chief architectural expression from the fenestral arrangement and cornice, which ought to be open and indicative of purpose. If a pediment be attempted it should certainly be moderate and retiring, not crowded up with sculpture or terminals, that would immediately vie with those of the town hall. The façade facing the latter ought certainly to be treated as one elevation with the front, and if possible we think the additional stories of the municipal offices support the principle that they should be pronounced instead of appearing to be incorporated under one roof. We think that the basement should be of stone rusticated, and we favour those designs which have no pilasters, or deal sparingly with them. The Cornhill is the most conspicuous site in Ipswich, and it would be an irretrievable mistake for the Corporation to commit themselves to any design that either lacks architectural character or is shorn of the best features it has, or to meagre proportions by a process of cutting down afterwards.

BUILDING MACHINERY.

ALMOST within the limits of the present generation the old-fashioned "builder" has developed into the modern "contractor"—an employer of countless "hands," who in lieu of the "yard" of former times, has his wharf on the river; his steam saw-mills, his brick-fields, and, perchance, his quarries; who imports his own timber, and burns his own lime, and not unfrequently covers his own freehold estates with houses, the ground-rents of which represent a satisfactory income calculated by the tens of thousands per annum. There is no need of examining how this altered condition of affairs came about; how from the plan still pursued in the provinces, wherein each trade is contracted for separately by masters in that particular branch, certain bold innovators came forward with proposals to take the entire job, and sub-contract with the tradesmen in each department; and how

ultimately these "general contractors" became the wealthy capitalists of our own day, and employed workmen of every kind, and not only supplied all the labour required in the execution of great works, but became, or are gradually becoming, providers of the varied materials used in building. We only glance at this matter in order to show that the contractor who has so far concentrated all the small fish into his net is in a first-rate position to avail himself to the full extent of every modern mechanical appliance for carrying out the extensive undertakings upon which he embarks, and for saving to the utmost that most costly of all items to the manufacturer, *human labour*. Of course, in his workshops, his mills, and his brick-fields he takes care to provide himself with the best of machine-tools, and, if his workmen do not combine to prevent him, he will be the first to obtain every new description of wood and stone-working machinery, and every similar appliance for preparing his materials. He is well aware of the pecuniary advantages to be gained by strict adherence to the maxim of the nineteenth century, "Never employ men to do what can be done as well, or better, by machinery," and for no one has the manufacturer of labour-saving machinery worked to greater advantage than for the builder. In all these respects his plant is little short of perfect; but when we get on to the scene of his building operations, the place where the materials so skilfully prepared have to be erected and placed in position, we find many anomalies, many signs of the prevalence of old-fashioned ideas, and much that seems scarcely in accord with the progress we have briefly alluded to in the other departments of his works. We propose to glance briefly at the different stages of the progress of an important work, and see where we have found antiquated modes of working to linger, and in what respect it appears possible to suggest improvements; in short, to sum up all that we find on a large and important works in London, in the way of mechanical aids to what we may term the erection of the building. We have a portable engine, of a type specially adapted for agriculturists; a clumsy and ill-designed mortar mill; a steam-pump, whose chief merit appears to be that it furnishes a standing job to the fitter to keep it in order; an overhead travelling crane; and sometimes a steam-hoist. Now, when we reckon up the numerous and intricate operations which are involved in the erection of a large building, this list, which is a more than usually complete one, leaves much to be desired. In small works we rarely find anything beyond the mortar-mill and the portable engine.

On turning to our advertisement pages we find many firms offering to the trade the most varied assortment of what we may call workshop plant; but the machinery specially adapted for the works seems to have attracted little notice among mechanical engineers, and it is to this class of building machinery we wish to call attention. On visiting a little while ago one of the largest works in progress abroad, upon which between 3,000 and 4,000 workmen were employed, we found that the united power of the engines (chiefly used in pumping and mortar-mixing) was under 100 horse-power, and that in scores of cases where a simple machine might have done the work of a dozen men no idea seemed to have entered the head of the employers that the work was being done wastefully. There can be no question that in this matter they are in France and Germany even more behindhand than we are. In France that most valuable appliance the light iron tramway, and the so-called contractor's engine was almost unknown until a year or two ago.

In our survey of the work, we may begin with the excavation, and here, though there is an ample field for improved modes of working, the navvy with his spade still holds

his own, and such a thing as a steam-excavator, though quite possible on a scale which could be profitably employed on the foundations even of an ordinary warehouse, is only introduced on the most extensive railways, docks, or canals, and has never, so far as we know, been constructed of a size suitable for the builder. Something of the nature of a revolving scoop, which could be advanced on a light framework similar to a drill, and would raise the earth as fast as it was removed, by means of an elevator, into the carts, would accomplish what we have in view, and do our digging far better and more quickly than a gang of men.

If we visit the site where they are preparing the foundation for a large building situated in a narrow street in the City, we cannot fail to be astonished at the straits to which the foreman is driven to provide a cart-road at an almost impossible angle to reach the lowest level, and the terrible strains to which the poor horses are subjected in dragging out the loaded carts. Failing the steam-navvy, with a self-delivery for the excavated materials, we would advocate the introduction of a simple form of hoist which could be very easily rigged up, and which could be used both to raise the barrows from the trenches, as well as subsequently to lift the bricks, the mortar, and the men to the different levels of the building; a jointed framework, which could be readily run up. An additional stage would be the most generally useful form. Within this frame should work a platform large enough for a wheelbarrow, or a small four-wheel truck. A wheelbarrow, by the bye, is mechanically a wholly obsolete contrivance, and ought years ago to have been sent to the old curiosity-shop. Now that iron is so cheap, a small tramway with a 2-feet gauge can be readily and quickly laid down, and light trucks made of wrought-iron, which would contain from 2cwt. to 3cwt. each, would enable a man to do three times the work he now does with a barrow. We might expect in Spain or in Russia to see men wheeling loads before them in such a way that they manage to carry nearly half the weight themselves; but in this year of grace 1879 it seems almost too ridiculous to see in London a long line of men toiling up ladders with hods upon their shoulders. Just consider what this involves—150lb. of flesh and blood climbing up a scaffold with 50lb. of materials! The cost of raising each ton ranging, at the present rate of wages, from 1s. to 1s. 6d., in accordance with the height of the building! The horse-lift is infinitely better than this, but a horse-run does not pay for anything under 25ft.—showing at a glance what a relatively expensive way even this must be of hoisting the materials. Relatively we mean to steam-power, which would do the work for 1d. per ton. What the London builder wants is a well considered 7 to 10 horse-power engine of the semi-portable type, with a grate arranged for burning coke. In connection with this he must have the means of driving a good 8ft. to 9ft. mortar mill—(the small mills are of no use) and if he can contrive to take some of his power, by means of shafting, to work a rocking sieve for sand-screening and a small band saw to save the time of the carpenters, so much the better. His engine will work the winding gear for the hoist, and before the mortar is wanted it will do all the excavation for him. Surely one of the many makers of portable engines could give us what is wanted, from this brief description of the work it would have to do. We have mentioned the sieve for screening and washing the sand; nothing could be easier than to do this work with a machine of the most simple kind. It is true that the cost of this does not form a very serious item, even in the largest buildings, and that it may not

pay to have a special band from the shafting to drive the sieves; but in the contractors' engine and fittings of the future, it might be as well to remember this. Next we come to the bricklaying; this cannot be done by machinery, and all the more reason for abolishing it entirely. Of all the antiquated methods of going out of our way to make work, the use of bricks is about the worst. Why, with all our boasted progress, we find ourselves at the end of the 19th century sticking together bad bricks with worse mortar, is wholly incomprehensible, and can only be explained by our desperate attachment to conservative principles.

With an excellent and reliable material like cement concrete we ought years and years ago to have found out a mode of facing it with some glazed impermeable surface, and trusted to walls made of concrete which are in every respect vastly superior to brickwork. We shall doubtless come to this; but probably not until it becomes something approaching felony to employ bricks. We have, we fear, after all, pointed out only very few of the unworkmanlike ways of building now in vogue. To name another clumsy, blundering plan, rendering our workmen liable to all manner of accidents, just look at our system of scaffolding with fixed poles and cords—how long will this muddling plan prevail, we wonder? Here there are signs of improvement, however, as an excellent invention has been recently introduced for using square timber for the uprights and ledgers, and employing shoes and rings made of galvanised iron. Something far better, and by no means difficult to arrange, would be a platform of light iron-work, raised 6in., say, at a time by hydraulic pressure or a simple rack and pinion. In scaffolding of this kind our French neighbours are very ingenious. Look where we will, however, over the entire works, we find everywhere a tendency to plod along in the old grooves, with an entire forgetfulness of the invention and progress which are the characteristics of the present day; and if by these criticisms, which are offered in no unfriendly spirit, we can succeed in directing attention to points capable of improvement, we shall not have failed in our object.

PARAPETS AND CORNICES.

THERE has been a return of late to roofs with gutters and parapets, but the practice has only been brought about by the change of fashion in architectural design, and not by any well-founded preference for a system of construction that must be more costly, and has always been associated with imperfect and worn-out systems of architecture. The crowning of the wall has always been one of the distinctive features in every style of ancient or modern times; and from the hollow, lotus-adorned cornice of the Egyptians to the best examples of Greek and Gothic, we find the cornice and parapet struggling for supremacy. With the Greek architects, the projecting members of the cornice formed the constructional drip protecting the wall below it, and allowing the rain to flow off the roof. The Doric cornice is now believed, with some show of reason, to have arisen from the necessities of timber construction, in which the cross timbers became at length transmuted into triglyphs, while the upper members formed the edge of the covering of slabs or tiles, as now used in the East. In the course of time this order of things was changed. The constructive motive was lost sight of, and the wall, and not the roof, became the object of attention. The Romans were the first people who made the walls of a building a mere mask to the internal structure, and this idea was never totally lost sight of, even by the Mediæval

builders, who built parapets to their church roofs both over the naves and aisles. The modern architect revived the idea of having roofs hidden, and at the time of the Greek mania very few houses were without parapets and concealed gutters. All at once the spirit of the dream was changed; the parapet was condemned as false, as encouraging flat roofs that never effectually kept the wet out, while it disguised everything in the shape of chimneys. During fifty years the anti-parapet fever remained unabated. It was thought heathenish to hide roofs and to surround buildings with balustrades and urns. Recently, however, this interdiction has ceased, and the Queen Anne revivalists have once more taken to the idea of building parapets round the tops of houses and public buildings. After all, there may be something in the notion that parapets answer a useful purpose in intercepting snowdrifts, broken tiles and slates, and in affording a protection to those engaged in repairs and cleaning. It must not be imagined that the question is a party one simply, for it so happens that there are numerous excellent examples of buildings, both classic and Gothic, where the overhanging roof and cornice are adopted. In the Italian Renaissance, the projecting eaves cornice was always made a most important source of effect. We may mention the Farnese, the Pitti, Pandolfini, and Strozzi palaces particularly, as illustrating the importance attached by the Italian revivalists to the cornice, as the only crowning member of buildings. If we turn to the English revivalists, and especially Inigo Jones, whose works are just now held in fresh esteem, we find the parapet omitted in several buildings. We may name Ambresbury, in Wiltshire, and many mansions erected by the disciples of the same master, where the cornice is made the actual springing of the roof. At Chelsea, in Cheyne-walk, and in nearly every old square and street in London—the courts of the Temple particularly, the cornice is made a highly ornamental feature. Many of the latter are in cut and rubbed brick, and have modillions or blocks, and will well repay the admirer of our old sixteenth or seventeenth century architecture by a visit. While, however, such excellent examples of pure detail abound on every side readily accessible, it is somewhat ludicrous to see the attempts of certain revivalists among us to “snatch a grace beyond the rules of art” by designing or copying cornices of a nondescript kind, and by erecting parapets of the proportion of a breast wall to a rampart. One of the most noticeable features in the old brick houses of the seventeenth and eighteenth centuries, is the singular charm of the brick or stone cornices under a green-slatted or red-tiled roof; but it is a rather perverse fact that few of our buildings that imitate with such tenacious-like closeness the accidental features of this style have exhibited the one source of effect which the seventeenth century architect made so much of.

On the utilitarian aspect of parapet or projecting eaves we need not here enlarge; but we may at once observe that both are useful expedients under certain conditions of building. The parapet is, without doubt, a useful adjunct to the roofs of large town buildings as a means of providing access to the roofs; on the other hand, it forms a lodgment for snow, and a source of dampness to the rooms below, unless the precaution is taken of introducing a damp-proof course immediately below the flashing of the gutter. Its utility as an outside passage or gutter becomes interfered with when dormers are constructed, unless these be brought out on the plane of façade; on the other hand, the projecting eaves become a protection to the walls, and give even greater sanction to dormers as an architectural relief. There is one kind of parapet

that combines the advantages of both modes of construction to a certain degree, and this is the balustraded or pierced parapet; but we have seldom seen any satisfactory examples of them.

BAD MORTAR AND ROTTEN WALLS.

LAST week we drew attention to a case—an example of hundreds in the suburbs of the metropolis that never come to light—in which a builder was summoned by the district surveyor for East Hackney for using improper mortar, the magistrate ordering the houses to be pulled down. In this instance the mortar produced by Mr. Gould, the surveyor, was nothing but dirt coloured by a little lime, a kind of material that is by no means an uncommon substitute for lime and sand in the suburbs of London. It so happens that the “jerry builder” who indulges in this pernicious system of work has a very plausible excuse ready whenever he is caught. In more than one case lately it has been contended that the dirty-looking stuff is a compound of burnt ballast in lieu of sand, and evidence to this effect was produced in the case before us by another surveyor called to support the defendant. It seems to have been satisfactorily proved, however, and in a most amusing manner, that the ballast in question was a lump of canal mud, and that it had never been subjected to the action of fire may well be believed. It may be necessary to draw attention to the fact that ashes and cinders are frequently used instead of sand in the preparation of mortar, and that in the suburbs especially there is a strong temptation to use these materials for sand. If we could be sure of burnt clay or ashes free from dirt and impurities being used, there would be no objection; but, unfortunately, these materials are too often a disguise to the quantity of old mortar and dust-heaps that are utilised. There is one difficulty we may point out in the detection of this dirty kind of mortar, and that is the quality of lime used, if any. Only one means can be adopted to discover the efficiency of such a compound, namely, the immersion of a dried piece in water. If it has really any of the pretended ingredients, such as ashes or burnt clay pure and dry, mixed with good stone lime, the lump of mortar will remain hard; but if otherwise, it will quickly decompose, and run into sludge. We caution all those who have misgivings to apply this test. Such material as burnt clay should invariably be reduced to a fine powder before being mixed with the lime. It is not, perhaps, generally known that there are ingredients which rather improve mortar if used instead of sand. We may briefly refer to some of these. Smiths’ ashes we have occasionally pointed out as adding materially to the strength of mortar, though they are chiefly used to impart a black or dark colour. The scorie from iron works, and the slag from furnaces, are employed with advantage when quite clean. Burnt clay is also used as a substitute. It is prepared by placing moist stiff clay over a coal and wood fire, and as the clay becomes burnt fresh layers of it with “breeze” or ashes are laid on. The clay should be thoroughly burnt. Besides these materials, crushed stone is often used. It appears from General Scott’s experiments, that Portland cement and sand of equal measures withstood 504lb. upon an area of 10in. before breaking; with a proportion of 1 to 2 a weight of 433lb.; with 1 to 3 of 303lb., of 1 to 4 of 420lb., the age of mortar being eleven days. The following are given by the same authority for mortar in brickwork built with ordinary London stock bricks:—

	Parts by measure.	Quicklime.	Sand.
Fat limes	1	3	
Feebly hydraulic limes ..	1	2½	
Hydraulic limes (Lias) ..	1	2	
Roman cement	1	1½	
Portland cement	1	5	
Scott’s	1	4	

For fat lime mortar, fine sand has been found objectionable, as it prevents the penetration which is necessary for setting. On the whole, we consider coarse angular sand makes the best mortar, an opinion that is confirmed by all the old and hard mortars we have ever examined. It is said that calcareous sands make stronger mortars than siliceous sands, though we think this rather doubtful, as in the case of building stones, those sandstones in which the ingredient is chiefly quartz united by a cementing medium of a carbonate of lime character, are found to resist atmospheric influences far better than when the grains are of carbonate of lime embedded in a siliceous cement. For damp situations, as cellars and basements, fat lime should be avoided, as it retains moisture; and when once it becomes dry mortar made with it decomposes, and falls into a friable dust. Half the miserably damp and insecure houses in the suburbs of London, which occasionally yield and give rise to coroner’s inquiries, are built of fat limes on account of their cheapness and ease of working; after they have been occupied for a short time, door and window frames begin to show signs of weakness, the mortar has no hold, and loose masses of dry sand whitened by the lime, fall out on the least disturbance. Who has not lost both temper and patience in driving a nail into walls built of such friable material? If one attempts to draw a nail a puff of white dust is produced, and the mortar seems to have entirely lost its cohesive power and to have become so much sand. Mortar, with fat lime used externally, is still worse: it imbibes moisture with great avidity, and the first frost breaks away the outer crust. Pointing is the only remedy to prevent a further attack on the stability of the wall. We are glad to see that the amendments to the Metropolitan Building Act have not overlooked the subject of sand and lime in the mortar to be used, though we yet wonder how the provisions are to be effectually enforced in some cases. For buildings of ordinary kind limes of a slightly hydraulic character are required, such as grey chalk lime, called generally “stone lime” in specifications, and the lias lime. The last in its natural state is of a dark blue colour, hence called “blue lias.” There is considerable adulteration, however, to be guarded against, such as sand, &c., and the test with an acid to detect the amount of effervescence that takes place should be adopted in important buildings. Mr. Reid suggests, as a better plan, to burn a little of the stone in a small kiln to judge by the slaking; and generally, hydraulic lime should have a clayey odour and an earthy texture.

ARCHITECTURAL MOSAIC.

V.—MODERN MOSAIC (continued).

THE revival of marble mosaic as an adjunct to architecture is even more recent than that of ceramic and glass mosaic. The kind of marble work practised almost exclusively during the middle ages was the *Opus Alexandrinum*, in which every fragment was shaped into some regular geometrical form; but of true marble mosaic (*Opus musivum*), in which the fragments were of irregular shape, and each fashioned by the workman as he required it, we can call to mind no later example than the Baths of Caracalla, at Rome, which date back so far as the year 211 B.C. But about twenty years ago an obscure body of Italian

workmen commenced its re-introduction, travelling about to various cities of Europe, like the Freemasons of the middle ages, wherever they could find employment, with very little organisation and very small means. Their work consisted mainly of an imitation of the ancient *Opus incertum*, that is, small irregularly-shaped fragments of variously coloured marbles, not combined into any particular pattern, but with an eye to a pleasing combination and harmony of colour, which was surrounded by a border of more regular *Opus vermiculatum*, also in marble, in which pictorial designs were introduced. These travelling workmen laid many pavements of this kind in Paris, Vienna, Pesth, and in several towns of the South of France, among which may be named Nîmes and Lyons, before the value of their work began to be generally recognised. The introduction of similar work into this country is due to Mr. Burke, of Newman-street, London, whose attention was attracted by a pavement at the Tribunal of Commerce at Paris, about six or seven years ago. That gentleman at once engaged the services of a number of these workmen, and commenced the construction of similar pavements as a special business both at London and Paris. Since that time his firm have laid many pavements in public buildings, among which may be specified the Manchester Town Hall, the Persian Court of South Kensington Museum, and all the floors of the new Natural History Museum not yet opened. Other firms have also entered largely into the trade, which is growing with wonderful rapidity, and the list of architects who order its use contains many of the most eminent names in the profession. One singular fact in connection with this kind of work is that not only do all the good workmen come from Italy, but the best workmen are all from one particular province, that of Udine, north of Venice. It is only now and then that a Piedmontese, a Milanese, a Roman, or a Neapolitan can be taught to be a good mosaicist in this particular branch of the art.

There are two kinds of work recognised—major and minor. In the major work, the tessere are placed by hand in fairish order, with an eye to combination of colour; whilst in the minor, the fragments being previously mixed as to colour in certain proportions are scattered at random over the surface of cement, somewhat resembling the way that stones are spread over a macadamised road. One element of the greatest importance in laying these pavements is the foundation. We have seen pavements which have given way because fragments of wood and decaying rubbish have been carelessly left underneath. The following is Mr. Burke’s description of the process of laying his pavements. Upon a firm and solid bed of concrete is imposed a coating of mastic, varying in substance according to circumstances. Into this mastic the tessere or irregular cubes of various coloured marbles about half-an-inch square, are hammered, so that each one is entirely surrounded by the cementitious preparation, the roughnesses on all sides affording an excellent key. A sufficient surface being laid, the workman with a rammer, somewhat similar to those used in roads for driving down granite paving, beats and rams down all the tessere, and then further consolidates the whole, by rolling over it a heavy granite or stone roller. It will thus be seen that the principle of this work is the thorough and entire consolidation of the marble cubes with the mastic, and of the latter with the concrete foundations. When the mastic has set the floor is sanded down to a uniform level, and the colours are brought out by various different means.

Marble mosaic has also recently been introduced as a means of profitably employing the female prisoners in the convict prison at Woking. Such labour is, of course, not

expensive, and the result is a very cheap pavement, which is manufactured in the prison and supplied at a fixed price per square yard. The floor of the passage in the Architectural Court at South Kensington is laid with this material, where the design, by Mr. Moody, is very effective, and the pavement appears smooth, well-laid, and likely to prove durable. We have also met with a statement that it is about to be used extensively at St. Paul's Cathedral, and we must confess to a sentimental objection to labour of such a kind being employed there. Every well-intentioned effort to reform criminals by giving them useful occupation deserves respect, but we cannot quite reconcile ourselves to the association of it with work which requires artistic taste and feeling. One could hardly walk over such a pavement in a sacred building, where every decoration is supposed to have some religious association, without being reminded of the pavement of a place of very different character, which some authorities declare consists entirely of "good intentions."

Opus Alexandrinum work is very little used in modern pavements, on account of the expensiveness both of the hard stones and marbles employed, and of the labour in sawing, grinding, shaping, and polishing each individual fragment; but we have seen some very good imitations of ancient patterns by Messrs. Poole, the masons to Westminster Abbey. The process of work, laying the shaped fragments in grooves of marble, is so like ordinary masons' work—executed, however, on a small scale—that any description of it would be unnecessary and superfluous.

Florentine modern mosaic is scarcely practised out of Italy. It is of two kinds, viz.—1. *Pietre-dure*, in which various objects are depicted in relief in coloured stones; and 2. *Pietre-commesse*, which consists of precious stones, as agates, jaspers, lapis-lazuli, &c., cut into thin veneers and carefully inlaid. Its use is very restricted, indeed, owing to the very expensive nature both of the materials and the labour which is spent upon them. None but the hardest stones are employed; every separate piece must be backed by thicker slices of slate or marble to obtain additional strength, and every minute portion must be ground until it exactly corresponds with the pattern previously cut. It is used chiefly for the decoration of altars and tombs, or for cabinets, tops of tables, coffers, and the like; and extraordinary effects are produced by taking advantage of the natural tints and shades of various coloured marbles in the imitation of fruits, flowers, and ornaments. In construction it most nearly resembles the ancient *Opus Sectile*, described in our first article.

Another kind of sectile work which is usually classed among the mosaics, although somewhat improperly so, is the modern French process invented by the late Baron Triqueti, and very effectively employed in the Memorial Chapel at Windsor. In this method the thin slabs of marble are very large, and shaped to follow the outlines of the design. White marble and marbles of various tints are employed, the outlines of the design being drawn in thin black marble upon a grey ground. When the whole is ground smooth and polished the effect is produced of a delicately-tinted and outlined drawing, with the advantage that it is fadeless and imperishable.

The marbles of Italy, as worked in modern days, present a wonderful variety of shades of colour, which enable the artists of Rome to reproduce many of the paintings of the great masters with such fidelity that close examination is required to distinguish them from the originals. A very extensive collection of these marbles, in countless varieties of shade, may be inspected by all who wish to see them on the walls of the Geological

Museum, in Jernyn-street. The ancients frequently combined both glass and marble mosaic in the same composition, but this practice is not adopted in modern work, which is always exclusively either glass, marble, or pottery. Modern marble mosaic is only just coming into use for wall decorations, but with the great variety of variously tinted natural limestones and marbles, we have lately seen, there can be no reason why for certain purposes it should not maintain its place side by side with glass and tile work. Messrs. Burke and Co. are at the present moment engaged upon very extensive marble mosaic decorations on the walls of the Guards' Chapel, in St. James's Park, under the superintendence, and after the designs, of Mr. Street. When these are completed they will form, we believe, the first important example of the application of marble, pure and simple, to artistic work of such a character; and as in the same chapel Dr. Salviati is also executing a "Majesty" in Venetian gold mosaic, the gift of Queen Victoria, the friendly juxtaposition of glass and marble work will give an admirable opportunity for study and comparison.

THE "BUILDING NEWS" DESIGNING CLUB.

THREE VILLAGE SHOPS.

THE competition for three village shops has elicited a more than usual amount of artistic ability. The conditions laid down were clearly in view of a design of modest pretensions, such as one may meet with in a village or retired suburb. "Motto J." which we place first, has cleverly seized the idea, and has given us something at once English and homely. The style is peculiarly quaint though unaffected; the slightly projecting gabled bays corbelled over the shops and running up through the eaves; the shop windows and corner oriel being exceedingly plain, but effective. The upper stories are proposed to be "of timber covered with plaster and Portland cement," the roof is of red tiles, and the woodwork is intended to be painted dark peacock blue with white window bars. In the plans the corner and end shops are well treated, the private entrance and stairs being placed transversely between the shop and living-room. The author makes the living room to answer for the kitchen. We do not understand how the stairs to the centre house is lighted unless by a skylight. Externally, the treatment of the shop-windows is pronounced without being unpleasantly suggestive of town or suburban fronts, and the pent-roof over the butcher's shop is appropriate and useful. "Sin circle" is certainly clever in his plan. The corner shop appropriated to the grocer is ingeniously arranged in the supporting piers and window fronts, a small side bay being shown in the return street. The hall, stairs, and offices, are compactly planned, but the other shops are cramped by the halls and staircases. Large sitting-rooms are obtained over the shops. There is a pleasing variety in the elevation and in the treatment of window-fronts, though the brackets below breastsummers would have been better omitted. The stories above are half-timbered, the upper story tiled, and the author has pleasingly varied the houses without ostentation. "Noah" sends a charming old English front, the centre house being timbered with gable while the two end houses are in brick. There are decided touches of Queen Anne in the windows and small bays, but the composition, with the exception of the balcony corner, which does not well carry round the lines, is pretty coherent. The shop windows, certainly, are small. The author's plan is compact. Behind the shop in each house is a small kitchen with projecting scullery and pantry, the coals and dust forming a narrow lean-to on the other side. Stairs are well placed and lighted, and a living-room is obtained over each shop. The author has, however, not economised his space to advantage in the case of the corner (butcher's) shop. In this case the entrance might have been at the side, instead of through the shop from the front. One of the best designs we have received, equal in merit to the two last, is "Be to its merits very kind," &c. The author of it has shown a very decided improvement since he joined our club,

which we are very pleased to acknowledge. His elevations exhibit a suitable and pleasing Old English treatment, simple and highly picturesque, without any affectation of manner or extravagance of feature. The corner house is gabled and devoted to a butcher's shop, the other two houses are relieved by bold plain square bay windows two stories high gabled as dormers in the roof. They have plain mullions and casements, and are tiled between. A pent roof divides the shops from the upper stories. The style chosen is a Late Domestic Gothic verging upon the Revival, and exemplified in numerous old buildings in London and elsewhere of between the 16th and 17th centuries. Two well-drawn perspective views are given, but the drawing of the larger one is taken from a point of view that is not artistically, if literally correct. Although the point of sight is supposed to be somewhere within the gabled house, it is conventionally proper to show the return side in sharp perspective; as drawn, it has the appearance of being an acute angle. The plans are carefully worked out with all dimensions. The butcher's shop is 18ft. 6in. by 12ft. 6in., with a side private entrance; behind a living-room and kitchen projection. The two other houses have front passage entrances to the private rooms, bayshop windows, small living-rooms behind the shops, and projection for kitchen offices; on the first-floor sitting-rooms are obtained over the shops, and the stairs and conveniences are well lighted and planned. "Josephus Orangeblossom" contributes a carefully drawn design in a suitable Gothic style; the middle house is gabled and timber framed, and the end houses are tiled in the upper story. The shop windows are simply arched openings, filled in with mullions and transoms. The grocer's shop is at the corner with canted corner entrance. An entrance on the return side leads into a kitchen, the scullery, pantry, fuel shed, &c., being comprised in a long shed in rear. The middle house has a lobby entrance with side-door to shop. This economises the space for show-board and window front; the stairs placed crosswise between shop and kitchen are ingeniously lighted by a small area at the side of latter. Upstairs each house has a front sitting-room and back bedroom, and three small bedrooms on the second floor; these are certainly cramped. Considerable ingenuity is evinced in the planning, and a flue for ventilating the butcher's shop shown. The author sends a sketch perspective. "Honey Dew" is an appropriate and picturesque design in a timber and parget style, with large end gable and dormers. The shop-fronts are neat in treatment with recessed entrances; the upper windows have mullions and casements, corbelled as dormers of the bedrooms in roof. The shops, 14ft. by 13ft. 8in., have angle doorways; a kitchen with scullery as lean-to projection, and a stairs fronting the private entrances make up the ground-floor. Above shops are sitting-rooms and bedrooms behind. We take exception to the front w.c.s. over private entrances, which cut off a passage at side of sitting-room. The drawings are carefully executed. "Pogmore" sends a more pretentious row suitable rather for a suburb or small town, though not without merit. The shop-fronts are too ostentatious for a village, and the author has not been successful in breaking through that stereotyped combination of shop-front and house which makes the modern street so wearisome. Otherwise the upper windows are effective. In plan the faults are the cutting up of the fronts of the two middle houses by an entrance on each side of it; the long narrow passages to the living rooms behind, the ill-lighted stairs, the want of a pantry near living room, and the small bedrooms in the second-floor. A basement is provided. The author estimates the row at 6d. a cubic foot, amounting to £2,513. Design marked "Curiose" is not without merit in external treatment; the shop-fronts and upper timbered stories slightly corbelled out are picturesque in grouping, but the angle protuberance above roof is clumsy, and the gable between two houses makes them appear one. The private entrances are cramped and the stairs in front of doorways awkward, besides unnecessarily contracting the shops. The kitchen and scullery look small, and the upper arrangement of landing and rooms not economical. Estimate is £1,490. "Dunwich" sends an elaborate design in Late Gothic with three gables, and timber filling-in. The general features are suitable, but the detail is too ornate. The butcher's shop would have been

better at the corner. The plan is not without merit, but the front bed-rooms over the corner shop are cut up wastefully. The kitchen and offices are in basement—not desirable for a village. The estimate is £2,095. A little over-timbered is "Veritas Vincit"; the studwork is excessive almost to the verge of satiety. The staircases in the inner houses seem poorly lighted, otherwise the plans have merit and are well studied. A basement is provided for coal and goods. "Enigma" has a somewhat similar plan, though there was no necessity for a passage entrance between parlour and kitchen projection. The elevation is of framework and plaster, with flat projecting windows gabled at top. The timber filling-in between windows is a little too fanciful perhaps; but on the whole the treatment is suitable. "Juvenis" attempts the same style, but clearly falls into the common snare of superfluous ornament. The first-floor plan is spoilt by a small bedroom at the side of front sitting-room; and the narrow bedrooms above are quite as wasteful. A note says the "plastering is to be coloured red, and the studs to be painted dark brown" a contrast certainly rather too harlequinade-like to please us. "M. in leaves" arranges his frontage after a novel plan. The butcher's shop and house is detached from the other two by a passage-way for barrows, and the entrance halls and lobbies form projecting wings on the ground-floor, though the bedrooms on the upper plan sail over the areas left for light. The shops have by this arrangement a wide frontage. The elevation suffers from a peculiar irregularity of the windows and the flat-pitched dormers. The estimates are for butchers' and drapers' shops, £752 each; and for grocers', £833 17s. The elevation of "Amateur" is cut up rather unpleasantly, and there is a strained look about the centre gabled projection and hipped roof. In plan the side-entrance and staircase are awkward, and the lighting of the other stairs through closets unsatisfactory. In other respects economy has been studied. "Try" is economical in his planning, but the shops are pinched up by the entrances and breaks in walls, and the fronts are rather fantastical. It would have been better to have made a porch to each of the middle houses, and to have had a side doorway therefrom into shop, instead of reducing the show space by two doorways. The elevation is simple and broadly treated, and without the centre projecting porchway it would have possessed merit. The author has evidently improved in his style, and has a correct idea of country shops. "Ogmores" also has a simple but pleasing elevation, but the bay windows to the shops are too domestic-looking. The arrangement is certainly clever. "M. in leaves" (No. 2) shows a variation both in plan and elevation. Back shops are provided in connection with the front, and the plan is less objectionable as regards the construction; on the other hand, his elevations we have above referred to is better. Design by "Boz" is timber-framed, moderate, and suitable as regards elevation; the shop-fronts are artistically handled, but the plans are not contrived with sufficient regard to frontage of windows. "East Anglian" runs pretty close as regards plan. A lobby entrance is shown to two of the houses and shops, and the arrangement appears economical. We do not like the shop windows, but the upper part of elevation is better. "Elève" has attempted too much; the elevation would be more suited to a town thoroughfare, and the brick treatment of projecting windows and gables does not suggest a rural locality. The plans are better. "Factable," too pretentious in the ornament introduced; the passage entrances are wasteful, and the sitting and bedrooms are cramped. "H. T.," shown by a very sharp perspective sketch, is stronger in the plans than the elevation, which is covered with timber-work and panels. "Essayez" and "Speedy Method" both fail in their plans. The three gables of the first are undesirable; the latter's sketch is suggestive of something better in elevation. It is somewhat singular the lobby entrance has not been thought of by more as the least wasteful kind of entrance. In most of the plans, the back room has been made either a sitting-room or kitchen, with scullery and offices projection, the parlour being obtained on the first floor; but the best way of getting the staircase to avoid a cramped hall, and to preserve privacy, has been overlooked in many instances.

ENTRANCE GATES IN WROUGHT IRON.

The designs for these are not so satisfactory.

"Curiose" we place first, though the treatment of the panels is rather suggestive of cast iron than wrought. The piers are cleverly managed. "Motto J" is a much more spirited and original design; the cross braces are made the principal means of ornamentation, but the scrolls and thistles which spring out of them seem to lack coherency with the other panels of gate. The piers are well treated, with iron lamp-stands upon the top. A Japanese motive prevails in the ironwork, which is certainly appropriate for wrought iron. The next design of merit has the motto "Truth shall prevail." The author adopts a Gothic design; the lower panels and the upper filling-in with scroll work are decidedly characteristic of hammered metal, and the ornamental bosses are conventionalised in the right spirit. The piers are rather commonplace. "Nemo's" design is not without elegance in the ornamental treatment, and is a close pattern, but the gate-piers look like cast-iron, and are certainly effete reproductions. "Con Amore" sends a suitable design for wrought work. "Melina" is more characteristic of casting, but the details and general design are meritorious. "Ogmores" gates are also clever in the leafage of lower panels and trefoiled treatment above; the framing is also light, but the piers are less satisfactory. "Corvis" sends two designs. The upper one is too Gothicsque, the lower reminds us of one sent to the Paris Exhibition by Messrs. Barnard, Bishop, and Barnard. "Be to its merits very kind," &c.: this is a pleasing design, if the terminal ornaments were less in height. The alternative sketch has merits, but the spiral points are redundant. The details are well shown. "Yes or No" indulges too freely in long, unsupported sprigs of iron, which could easily be knocked or wrenched off; in other respects the design is meritorious. "Steffano" sends a rather used-up Gothic pattern; the twisted rail and standards in upper panels do not appear to belong to the lower part; the pier caps are wanting in good design. "Try" sends a better conception for hammered work, though the pseudo-Gothic piers are rather ludicrous in design. "Norwich" is too florid; the riveted sprigs and the upper folial treatment are out of place. A rough sketch is sent under "Dum Spiro Spero," but the idea is commonplace. "Signum" is more suited for a cast-iron treatment, but the design lacks thought and purpose.

NOTES ON BUILDING CONSTRUCTION.— MATERIALS.*

THE third part of the advanced course, arranged to meet the requirements of the syllabus of the Science and Art Department on building construction, is just issued, and we take the opportunity of giving our readers some idea of its contents. We may mention that these notes are published with the intention of furnishing the student with information to enable him to pass the Honours examination of the Department. The volume now on our table deals with building materials, the two former volumes having treated of construction generally. Various authorities have been consulted in the preparation of the present notes, and we observe that the information required for the second stage, or that of an elementary kind, is printed in largotype, so that students can confine their attention to the notes necessary for their particular examination. The contents of Part III. show the scope of the work. Under the head of "Stone" we have the general characteristics of building stone, its durability, structure, facility for working, hardness, strength, weight, appearance, position in quarry, natural bed, destructive agents, as lichens and molluscs. The tests used for stone are pointed out, as its resistance to crushing, its absorption, its immersion in a solution of sulphate of soda (Brard's test), the acid test, Mr. C. H. Smith's test, &c. The scientific classification divides building-stones into—1, Siliceous; 2, argillaceous; and 3, calcareous; though for practical purposes they are arranged under—1, granites; 2, slates and schists; 3, sandstones; and 4, limestones. The position in the quarry is described, and the various beds of Portland discriminated. The notes on "natural beds" do not give us much definite information. It is stated that the natural bed is easily seen in the position of imbedded shells, "which were, of course, originally de-

posited horizontally; in others by thin streaks of vegetable matter or by traces of laminae which generally show out more distinctly if the stone is wetted." In some instances no signs of stratification are visible, but a good reason it is said can tell the natural bed by the "feel" of the grain in working the surface. Unfortunately, "good masons" are rare, and such a test is not likely to be of much advantage to the architect or engineer, to whom a knowledge of "natural bed" is most desirable. We believe an acid test, such as immersion in sulphuric acid, and a close or microscopic observation of the stone to be more practical. The latter test is used for discovering the most durable stone, though Mr. C. H. Smith's test is simpler and generally applicable. We give the note—"Break off a few chippings about the size of a shilling with a chisel, put them into a glass about one-third full of clear water, let them remain undisturbed at least half an hour. The water and specimens together should then be agitated by giving the glass a circular motion with the hand. If the stone be highly crystalline and the particles well cemented together, the water will remain clear and transparent, but if the specimens contain uncrystallised earthy powder the water will present a turbid or milky appearance in proportion to the quantity of loose matter contained in the stone. The stone should be damp when the fragments are chipped off." The notes on granite will be found pretty complete: a table of the principal quarries in Great Britain and Ireland is given. The varieties in common use are indicated, the most esteemed being those from Peterhead, Rubislaw, Stirling Hill, Dalbeattie, Ross of Mull, and others from the neighbourhood of Aberdeen. The information on slates will be found of service. As to quality, it is remarked, "a good slate should have a very fine grain"; veins are objectionable, particularly when they run with the length of slate, as it will be liable to split along the vein. The sizes of the slates and the various descriptions in use, the tests and different forms of slate are given. Similar information on sandstones, limestones, including marbles, is furnished, derived from a variety of sources. The notes on the principal kinds of stone in use are of practical value. Thus, of sandstones, Bramley Fall, the Yorkshire varieties, Seotgate Ash, Forest of Dean, Mansfield, and Cragleith, are mentioned. Of limestones, the marbles, Bath-stone, Portland, Chilmark, Kentish rag, yellow Mansfield, Caen, &c., are described, and these notes include the chemical composition, the several beds, uses, and the buildings in which each stone has been used. Artificial stone, such as Ransome's, Victoria, Chance's, and Rust's, is made the subject of a separate chapter; but the most suggestive chapter is that on "Preservation." The various kinds of processes are described under two classes, the first consisting of preparations containing dissolved organic substances, and the second of solutions of substances which act upon the constituents of the stone, or upon one another (when more than one is applied), so as to form insoluble compounds which fill up the pores, and make the stone denser, and more impervious and able to resist atmospheric influences. As regards paint, oil, paraffine, soft soap, they are only temporary protectives and discolour the stone, and it is stated on the authority of Dent, "There is no evidence to show that any methods such as these are likely to be successful in affording permanent protection to stone." According to the same author, the solution of baryta followed by a solution of ferro-silicic acid so as to fill the pores with an insoluble ferro-silicate; or a soluble oxalate of alumina applied to limestone, possesses the advantage of producing, by the changes they undergo within the stone, an insoluble substance without giving rise to the formation of any soluble salt likely to cause efflorescence, which attends the use of alkaline silicates. The tables will be found of considerable use. In the chapter on bricks, tiles, and terra-cotta, the constituents of brick-earth, and their chemical effect, are first treated, after which follows the classification of earths into plastic clays, loams, or marls; the colour of bricks is explained, and brickmaking is described and illustrated in some detail. After these the varieties of bricks are noticed, and the Building News of 1874 is quoted. The means of testing good bricks, their size, weight, and strength, both under compression and cross strain, are fully entered into. "Hurst's Handbook" and "Grant's Experiments" are laid under contribution here. The different forms of bricks are illustrated by diagrams; terra-cotta

* Notes on Building Construction. Part III.—Materials. London: Rivingtons.

and clay wares are also given. Thus Jennings', Doulton's, and the Broomhall Company's patents are figured, and the various forms of tile roof coverings noticed. The chapter on limes and cements appears to deal with these materials in a thorough manner. Concrete is thoroughly explained in its various forms and applications, and our own pages have here also been largely consulted. Selenitic, tar, iron, and lead concretes are described. In the notes on "efflorescence on walls," or "salt-petreing" as it is called, some valuable hints are given—namely, the avoidance of damp bricks containing iron pyrites or burnt with coal fires, limestones containing magnesia, also sea-sand or sea-water, and the following remedies are quoted:—
 "In the case of ashlar work, the surface may be covered with a wash of powdered stone, sand, and water, which is afterwards cleaned off. 2. Painting the surface is sometimes efficacious, if it is done before the efflorescence commences. The mortar before use may be treated to prevent it from causing efflorescence (1) by mixing with it any animal fatty matter; General Gilmore recommended 8lb. to 12lb. of fatty matter, 100lb. of quicklime, and 300lb. cement powder; (2) potash salts may be rendered harmless by adding hydrofluosilicic acid. Burnell, Gilmore, and Captain Abney, R.E., are the authorities quoted in these notes. Iron, and the other metals used in construction, form another chapter; the market forms of wrought iron, and their value and use are noticed, also brands of iron, varieties and tests for steel, the various processes for preserving iron and steel are detailed, and in short every kind of datum that has been accepted is furnished in the pithy form of notes. Timber and its decay, paints and varnishes, glass, and even nails find a place. We must caution our readers, however, not to think that the work is original, or that it professes to be a systematic treatise on materials. Its greatest value is that every fact has been winnowed of unnecessary verbiage, and given in the form of crisp notes, though these have been arranged in a rational order.

THE DISEASES OF BUILDING TIMBER.

IT seems odd that timber trees should be almost as liable to disease as man is, but it is undoubtedly true, and bad management causes the disease both in men and trees. Mr. James Brown, LL.D., states that the principal diseases likely to be brought on forest trees by bad management are:—1st, bark-bound; 2nd, moss or lichen upon the bark; 3rd, stag-horn tops; 4th, scale; 5th, premature bearing of seed; 6th, dropsy; 7th, ulcers; 8th, wounds; 9th, stunted growth of the young wood. Now, in addition to these defects, we have in the manufactured timber such matters to contend with as doatiness and the excess of sap and weariness, concerning which so many complaints are made. The disease called bark-bound is caused by the bark being girdled or bound about the wood of the tree, thereby preventing the proper flow of the sap, and also arresting the descent of woody matter between the wood and the bark. In this case, if the cause of the disease be not checked in proper time, the vital fluids become gradually checked, till at last the passages become entirely closed, and as the natural consequence the tree dies.

The appearances of lichen on the bark of trees is not always a decided symptom of disease in them, but may be occasioned by a temporary derangement in the outer bark; and if observed in time, like any other disease, may be arrested by removing the cause before it has had time to become decidedly fixed in the constitution of the trees affected.

Willows and poplars, which luxuriate in a soil rather damp than otherwise, generally become stag-horn-topped, when grown in a soil too dry for their healthy development. Elm, oak, ash, plane, &c., generally become in the same condition when the soil in which they may be growing is too damp for maintaining them in a healthy state.

Scale is a small white insect found clinging to the bark of some species. In forest trees it is most frequently found upon the ash while in a young state. The scale is easily distinguished by the appearance of the insect upon the surface of the bark. It presents itself as very numerous small white spots, like those on the bark of the birch; and if the observer

take a stone, and draw it roughly along the tree, he will kill many of the insects, and see their blood give a red tinge to the bark. As to premature bearing of seed, trees in a healthy, rapid-growing state are seldom found to produce seed till they have arrived at a considerable age and size. Generally speaking, any forest tree, bearing much seed, under forty years of age, is not likely ultimately to arrive at a valuable size. When a young tree produces a profusion of seed, there can be no doubt that it is in a state of premature decay; therefore we may be at once assured that such trees will not become valuable as timber.

Dropsy generally takes place in forest trees, either where the soil is too rich for them, or where there is an excess of moisture about the roots. The cause of it appears to be that the roots take into the system of the tree an excess of juice, which the bark and leaves cannot assimilate. In this disease unnatural swellings are observed on some part of the stem, which begin to rot and throw off the bark. It is incurable, and the only thing is to prevent it by attention to the ground being well drained and not over-rich.

An ulcer much resembles dropsy, but it is mostly confined to the larch and others of the coniferous tribes. Its appearance is that of a running sore upon the side of the stem, where the natural juices escape in the form of a hard resinous matter. This disease is mostly found upon young trees of these tribes, and is frequently occasioned by insects lodging their eggs in the inner bark, where the young live for a time, and destroy the albumen.

Wounds are often caused by the trees receiving damage on their stems by having the bark peeled off by accident in some way or other, which may prove injurious to their health, and not unfrequently be the cause of death; but any simple wound made upon a healthy tree is seldom or never found injurious, but soon heals up.

The stunted growth of young wood is at once apparent by the very short annual growth of young wood upon all the lateral branches, and may be in general the natural result of any of the diseases already described. Every tree when it has attained its full size and development of its nature, however healthy it may have hitherto been, gradually begins to fail in making young wood. This is the work of time, doing to the old tree what the disease does to the young.

Perhaps there is no British tree so worthy of cultivation as the larch. There are very few purposes for which the oak is now used, for which the larch would not answer as well. It grows rapidly, and attains maturity long before the oak. Unfortunately it has been planted haphazard in all kinds of soil, and the result has been the development of various forms of disease, and indeed whole plantations of it have died. The greater part of the diseases that are found to prevail in our larch plantations proceed from the deficient warmth about the roots of the tree, so that when cold cutting winds and slight frosts set in in spring, they are unable to resist the attack; their vessels shrink, their fluids become deranged, and disease follows as a natural result. But there can be no doubt that, judiciously managed, we might have a very valuable crop of larch every year for building purposes. It makes excellent floors for warehouses, and very difficult of ignition, a quality which cannot fail to recommend it, and the durability is well appreciated by all who have used it.

THE ACOUSTIC PROPERTIES OF BUILDINGS.

A PAPER was read the other day before the Musical Association on the above subject, and Mr. Cecil Saunders, the author, promulgated certain principles of interest to the architect, though we may differ from him in details. He justly urged it was difficult to find a building equally well adapted for the hearing of a large number of both slow and rapid music. Every listener must have 5 to 6 square feet of area; the latter figure was not too much for good music to be heard in comfort, this area including seat and passage room. For 1,000 auditors this would give 6,000 square feet, or 30,000 feet for 5,000, which was thought the greatest number that could hear well. Referring to the usual rectangular shape of room with end galleries, the author said that if such a room be very long, the waves of the sound were interrupted, and did not reach the distant listeners with their

initial crispness and force: if the room was too broad, there was a tendency to echo, from the sound being reflected from the walls as well. A circular hall was condemned when it had a high and vaulted ceiling; but the Surrey chapel in Blackfriars-road was pointed to as one of the most successful places for hearing. Now, the Surrey Chapel was a polygon of 16 sides, and was surrounded by a gallery. It had windows all round, with a circular roof over the centre, surmounted by a small lantern. It accommodated about 1,400 persons. Now the Surrey Chapel, unfortunately for Mr. Saunders' theory, was practically a round building, and yet there was no echo, showing that buildings of this form could be by some modifications made to answer all the advantages of a rectangle. It had been found experimentally that buildings planned on the circle or square answered better than those of ordinary proportions; and the architect does not require to be told that rooms of rectangular form, exceeding in length a proportion of 2 to 1, make under ordinary arrangements bad concert-rooms for music requiring delicacy of execution and expression. Mr. Saunders pointed to a square room with rounded corners as the model form of concert-hall, and thus has hit upon a mean between the circular and square forms. He proposes to place the orchestra, to hold 700 performers, in one corner, with tiers of seats in the angle. The organ he would make as low as possible, so as to permit of a low ceiling; the greater part of this instrument he proposes to place beneath the orchestra, with this object. A low ceiling is admitted by every authority to be necessary for acoustical effect, as every foot of additional height lessened the horizontal distance to which sound could be carried. An auditorium to seat 5,000, it was suggested, might have a circular arrangement of seats, and those should be so adjusted as to levels that those in the rear should be able to see over the heads of those in front, the seats in the angle opposite organ being almost as high as the top of orchestra. By this arrangement the sound-wave would reach those at the extreme end of room as clearly as those in front. The author recommends wood or zinc for the ceiling, the boards being tongued and glued together; plastering was considered the worst ceiling. It might be divided by circular or radial beams. With regard to the walls near orchestra, he thought looking-glasses to be good, as they reflected sound, but they should not be bedded in flannel; the other portions of walls he would board or cement. These suggestions, it will be seen, are somewhat crude, and we fear architects will be slow to avail themselves of them. We believe, however, the diagonal arrangement here recommended to be a good one for a square hall, as the waves of sound are better conducted than when the sound emanates from the middle of a flat side—one of the worst possible arrangements. The same advantage, however, can be gained by the octagon or polygonal plan. The chief difficulties are how to frame the roof to the best advantage, and how to obtain that architectural character desirable in a building. These are problems architects have yet to solve.

ERRORS IN TENDERS.

AT the meeting of the Portsmouth School Management Committee, on Tuesday week, the Sites, Works, and General Purposes Committee presented the following report:—"Your Committee report that tenders for building the Church-path School were received on the 18th instant, as follows: D. W. Lewis, £6,550; Longley, £7,980; Evans, £7,989; Burlidge, £8,081; Light, £8,099; Roberts, £8,176; Hide, £8,190; Hayter, £8,360; Cooper, £8,840; Quick, £8,939; Jenkins, £9,394. The first-named tender was selected for recommendation to the Board, subject to an approval of sureties, but was subsequently withdrawn by Mr. Lewis, in consequence of an alleged error of £1,000. Your Committee, under the circumstances, recommend that the present tenders be set aside, and advertisements inserted in the BUILDING News and principal local newspapers, for the purpose of obtaining fresh tenders for the job."

The Rev. H. Kitching moved, as an amendment, that "Inasmuch as the architect, who in this matter is the professional adviser to the Board, has distinctly stated that there was no sufficient foundation for the excuse that too short notice was given for pricing out the quantities; and moreover, in his private responsi-

bility, further advises the Board that in his judgment an advertisement for fresh tenders would be so contrary to the practice in the building trade that it was not at all probable that any respectable contractor would again tender, this Board resolves that from the tenders now before the Board one be forthwith accepted."

A long discussion ensued ultimately, and the Board divided, when there appeared for the amendment:—The Revs. H. Kitching, E. B. C. Churchill, and W. J. Connolly; Messrs. Cudlipp, Byerley, Blake, De Fraine, Tamsett, and Long—9. For the adoption of the Committee's report:—The Chairman, Vice-Chairman, the Rev. J. Ellis, and Mr. Whitcombe—4. The amendment was therefore declared carried. Mr. Cudlipp proposed, and Mr. Whitcombe seconded, that Mr. Evans' tender be accepted.—The Vice-Chairman moved, and Mr. De Fraine seconded, that Mr. Longley's tender be accepted.—Mr. Blake proposed, and the Rev. H. Kitching seconded, Mr. Light's tender.—Mr. Long proposed, and the Rev. E. B. C. Churchill seconded, Mr. Burbridge's tender.—On the first voting, the numbers were: Longley, 4; Evans, 4; Light, 5; Burbridge, 2. The latter name being the lowest, was withdrawn, and the voting then was: Longley, 4; Evans, 4; Light, 5. On being again put to the Board, Longley's name was withdrawn, and the final voting was, For Evans: The Chairman, Vice-Chairman, Long, Whitcombe, Cudlipp, De Fraine, and Ellis—7. For Light: Tamsett, Kitching, Connolly, Blake, Byerley, and Churchill—6. The tender of Mr. Evans was therefore accepted, subject to the other arrangements. The architect of the school is Mr. George Rake, of Portsea, whose estimate was £9 a head, or £8,100.

FRENCH WOOD-WORKING MACHINERY.

IN the course of a series of articles on wood-working machinery at the late Paris Exhibition, the *Engineer* makes some interesting comparisons of the distinguishing characteristics of French wood-working machines with those of other countries.

The employment of timber benches in almost all classes of French wood-working machinery, remarks our contemporary, is a feature not entirely to be overlooked; timber certainly has its disadvantages in its perishable nature, and its want of power to offer the same steadiness in the bearings as cast frames, but, from the class of work turned out by French manufacturers, we cannot suppose that they are so far behind their foreign competitors as to be ignorant of these points, nor so wedded to past traditions as to be oblivious of surrounding improvements; therefore, before condemning what appear to us as deficiencies in strength, we must first consider whether there be not some other grounds for their preference for apparently inferior tools before passing a hasty judgment on the construction of machines which are able to turn out equally good work with the English and American, and enable the manufacturers to compete on a parallel footing. In looking at a hand-power circular saw bench we could not help feeling the weight of this doubt. The only parts not of wood are the saw blade, spindle, driving gear, bearings, and tie bolts, and the two latter are of the very lightest description, yet the work turned out was good. The spindle is on the rise and fall system, the fence of wood, and the machine brought within reach of the most modest capital. The same remarks apply in general to an endless band saw machine for hand-power, the whole of the frame and table is of timber, with ten tie-rods. The standard for the top pulley is exactly the same in form as that of the log saw described, and is totally disconnected, excepting through the blade with the lower pulley, which runs on independent plummer blocks bolted to the longitudinal stays of the bench. The time during which the wood-working machinery in the French department was in operation was generally confined to three or four hours per diem with intervals of rest, and it was, therefore, not subjected to anything like the strain put on the English and American machines, which were hard at work from morning until night, so of course it is impossible to make a thorough comparison of their durability on equal grounds; but there they were, apparently as steady as ever, and, as far as the tests they have withstood, if not in quite as cleanly, at any rate in as serviceable a condition as when they entered the building.

A rule apparently generally adopted by French manufacturers of endless band saws is that the free space on the table be equal to the diameter of the pulleys; another, that the adoption of any particular form of casting be repeated throughout in all similar machines, the dimensions varying, of course, with the size and capacity. For this reason, there is often a greater lack of symmetry than might be expected from so artistic a nation. For instance, in an endless band saw machine with canting table the bed-plate is made to suit the standard, instead of all being cast in one symmetrical form. The under frame is very heavy-looking, and the arrangement for canting the table just about as awkward as one could well conceive. Two semi-circular arcs are fitted below, passing through cheek pieces bolted to the frame, and clamped by ordinary thumb screws. In all cases the blades are protected both fore and aft, the table by wooden splasher guards, the legs of the attendant alone being left exposed to the entanglement of a falling blade. Counterweight tensions are things unknown, a hand-wheel and screw being the only means adopted for adjustment of the blade. Wooden guides are in most cases fitted above and below the table, and generally one at the back of the blade. All pulleys are fitted with flanges, and, with the exception of the above-mentioned omission, as much attention is paid as possible to the protection of the attendant against accident. Timber framing is also employed for rests for sharpening band saws, and some of them are very primitive and rickety-looking machines.

THE MELBOURNE EXHIBITION.

THE foundation stone of the International Exhibition buildings, in the Carlton Gardens, Melbourne, was laid by the Governor on February 19th. The building will be an important addition to the architecture of Melbourne. The design is the work of Messrs. Reed and Barnes, the architects of the new Wilson Hall of the University of Melbourne, of which we give a description elsewhere, and many of the leading city structures. The salient features of the building (which will be the largest Melbourne has yet known) will be, first, a dome higher than the highest spire in the city, flanked by a number of smaller towers of pavilion shape; and secondly, a variety of ornamental details, mostly in such high relief as to utterly efface the dead-wall effect but too frequently conveyed under similar circumstances. The building, excluding the temporary annexes for machinery, &c., is cruciform, consisting of a nave 500ft. long running from east to west, and cut through its centre by a transept 270ft. deep, the ends of which are north and south. The main front faces Victoria-street, at nearly the point where stand the Model Schools. This transept is the leading feature of the fabric. At its south end is the chief portal—a tall arch 40ft. wide and 60ft. high, deeply recessed, and reached by a flight of broad stone steps. On each side are square towers 105ft. high. Some 50ft. behind the portico, and at the point where the transept intersects the nave, rises the dome, octagonal in form, and reaching the height of 223ft., being about 130 ft. above the main roof. As the dome rears itself above the main roof it is surrounded by tolerably massive columns, dividing groups of windows, and just above that point the tapering gradually begins. At its base the central tower is 100ft. square, but as its octagonal shape becomes defined the diameter is contracted to 60ft. The rest of the building is in keeping with its main features and with the nature of its design, which may be characterised as Italian Renaissance. On each side the central tower runs the nave, which from end to end measures fully 500ft. The exterior walls are, however, not those of the nave, but of the courts which intervene alongside them, an arrangement which accounts for the way in which the windows are designed. Finally, the exterior of the building may be said to be completed by a pavilion tower, 80ft. high, at each corner. The interior as it will strike the visitor may be briefly described. Entering the building by its south and chief portal, and passing beneath its fanlight and concomitant adornments, he will at once face the transept, 70ft. high, 60ft. broad in the clear, and besides, flanked with side galleries covering an additional space 20ft. wide. Proceeding some 30ft. further, he finds himself beneath the open dome, and at a point from which branch not only

the 270ft. long transept, running north and south, but the nave, which is 500ft. long, 70ft. high, and with the galleries, fully 100ft. wide. Between the nave and the outer walls on each side are several courts, each 200ft. long and 30ft. wide. The work of erecting the Exhibition building, and providing a large cellarage for wines, &c., is let to Mr. David Mitchell, for £61,407, and the contract is to be finished in 15 months from the 1st of the present month. The material to be used is brick, stuccoed. The roof will be of iron. The present plan is to build the dome of wood and iron, but it is not impossible that Mr. Reed's strong representations in favour of erecting the dome solidly of brick and iron from its base will be successful.

CHIPS.

The long-continued labour of restoring the lantern of the Cathedral at Rouen is complete.

New banking premises are about to be erected at Sudbury, for Messrs. Alexander and Co. Mr. Brightwen Bunyon, of Ipswich, is the architect.

It is intended to hold an exhibition of works of art and industry in York during the ensuing summer. The secretaries are W. Preter, M.D., W. Pumphrey, and E. Taylor, and communications should be addressed to them at the Guildhall, York.

A course of three lectures will be delivered in the galleries of the Natural History and Antiquities of the British Museum by Dr. Carter Blake, Lecturer on Comparative Anatomy, Westminster Hospital, on April 24, April 28, and April 30. Some of the keepers of the departments will give *vis à vis* explanations of the collections under their charge.

A novel copyright case was decided at the Maidstone County Court on Wednesday. A London artist, named Hills, having painted a picture of Old Maidstone Bridge, in oils, from a photograph taken by a local photographer, the latter sued him for having, as he alleged, infringed his copyright. After hearing the evidence, the Judge ordered the defendant to pay a penalty of a guinea, and to forfeit the picture, which was valued at thirty guineas, to the plaintiff. The plaintiff suggested that the painting should be given to the Maidstone Museum, and this course was agreed to.

A committee of the Medical Society of London was appointed last week to consider what measures could be taken to prevent the manufacture and sale of arsenical wall-papers. A great many facts in connection with this subject will be found in a little book we briefly noticed recently, "Our Domestic Poisons," by H. Carr, M.Inst.C.E. Mr. Carr is, we believe, actively moving for an inquiry into the use of dyes containing arsenic, and, if the statements contained in his book are true, there can be no doubt of the necessity for legislative interference.

The Rev. George Sanger, Vicar of Carlton-in-Cleveland, has made an extraordinary appeal in a circular addressed to his parishioners. He says:—"I feel sorry for the necessity of a letter to vindicate my conduct in rebuilding the parish church, which became so dangerous, after last August gales, that service could no longer be safely conducted under its roof. If I had not taken upon myself the rebuilding, the burden would have fallen upon the parish. You must all be aware that I have worked as few clergymen ever yet worked to rebuild the church. I worked as a bookbinder, to get the money, for two years; obtained the subscriptions by writing upwards of 2,000 letters; designed the building; acted as clerk of works and contractor; carved all the wood and stone, and worked with the men employed; and I ought to be allowed to complete the work in peace, not be publicly insulted for the benefit I have conferred upon the parish in building a church which, for elegance, is second to none in this locality." In conclusion, the writer begs for "£200 to finish the structure and its appendages."

An inquiry was recently held before Mr. J. T. Harrison, inspector to the Local Government Board at Buxton, respecting the borrowing of £2,500 by the Buxton Local Board for the purpose of completing the alterations at the new reservoir. Mr. J. H. Taylor, the surveyor, explained the efforts which were being made to render the reservoir serviceable by stopping the leakage. The extent of the leaks having been ascertained by coffer dams the reservoir had since been covered with concrete cement of an average thickness of 2½ in. to the height of 23ft. so that there was now little escape. The inspector questioned the witness in detail as to the cost of the work, remarking that he could scarcely understand that concrete cost 12s. 6d. per yard, even allowing for the nature of the work and the difficulty of getting material to it. He subsequently visited the reservoir and also the new gas-works in the Dale.

ST. GEORGE AND THE DRAGON, BY BARTOLOMEO PASSEROTTI.
—DETACHED VILLAS AT TURNHAM-GREEN.—HANDSWORTH
PUBLIC BUILDINGS.—CHURCH OF ST. JOHN THE EVANGELIST, MOLD.—HOUSES AT MANCHESTER AND NORTH-AMPTON.

OUR LITHOGRAPHIC ILLUSTRATIONS.

ST. GEORGE AND THE DRAGON, BY PASSEROTTI.

By the courtesy of Mr. J. P. Heseltine, of Kensington, we are enabled to present our readers to-day with a double-page fac-simile reproduction from the vigorous drawing of St. George and the Dragon, by Bartolomeo Passerotti. The original was exhibited this year at the Royal Academy Exhibition of Old Masters, and belongs to Mr. Heseltine's valuable and interesting collection. Formerly, it formed part of Baron Denon's and the late William Mayor's collections, which were sold some three years ago. Passerotti's pictures are not familiar to us, but there is a fine drawing by him in a similarly bold manner in the gallery of the Uffizi, at Florence. During the past few years we have reproduced several of Albert Dürer's engravings, lent for the purpose by Mr. William Burges and others. These were so well received by our readers that it is our intention to give from time to time other similar reproductions chiefly taken from the original autograph drawings of the Old Masters. Next week we hope to publish an interesting reproduction from one of Albert Dürer's own drawings; also from the late exhibition at Burlington House, and belonging to Mr. Edward J. Poynter, R.A., to whom we are indebted for the loan of the original.

DETACHED VILLAS, BEDFORD PARK.

LIKE the other houses at Bedford-park, near Turnham-green, which we have from time to time illustrated in the BUILDING NEWS,* the one which we publish to-day is designed by Mr. R. Norman Shaw, R.A., the architect to the estate. The object of the varied designs is to produce a quaint and homely effect, similar, as near as may be, to an old village, and this idea is supported by the old trees remaining in the gardens and roads, which have been arranged to preserve as many of the old group of trees as possible. The problem of building a small house is one of which almost every dabbler at building considers himself a master, though probably few problems require more taste and skill to work out well, with regard to suitable and convenient

treatment as well as limited expenditure. This being so any attempts in the right direction will always have an interest, while a peculiar value belongs to any example of this kind designed by so great and experienced a house builder as Mr. Norman Shaw. The only thing, of course, required is that his plans shall be faithfully and thoroughly well carried out, else most of the particular points in the design and characteristics of the style employed will be lost, and the whole thing is soon rendered little better than a sham. The design published to-day is intended for erection at a cost not exceeding £1,400, red brickwork being used for the walls and red tiles for the roof. The house is arranged all under a roof of one span, and on plan is scarcely more than a square, unquestionably the most economical form of building. The house would be improved rather by projecting the entrance bay two or three feet, and so increasing in size the lobby and bedroom over, still preserving the quaint effect of the elevation, which would be lost probably to a great extent if executed with so slight a projection as that now shown for the part referred to. The church, which we illustrated in January last, is now in progress of building, and the Club on the Estate will be formally opened on Tuesday next, the 22nd, by a concert by members of the Bedford Park Musical Society. Several houses are in course of erection, and with good supervision will be free from the objections inevitable, perhaps, in the experience of the past.

HANDSWORTH PUBLIC BUILDINGS.

THESE buildings, which are now on the eve of completion, have been carried out under the direction of Messrs. Alexander and Henman, architects, of Stockton-on-Tees and Middlesborough, whose designs were selected in competition. As originally planned, there was to have been a large public hall in place of the free library as now erected, but the sanction of the Local Government Board could not be obtained for the carrying out of that portion of the design, and although such a building is much needed in the district, the Local Board were reluctantly compelled to abandon that portion of their scheme. However, in place thereof, rooms suitable for a public library have been substituted. Some modifications of the original plans and elevations were consequently necessary, but the leading features of the design have been retained. The buildings comprise various offices for the surveyor, rate-collector, medical officer, nuisance inspector, and rooms for a resident porter on the ground floor and on the first floor; the board room, two committee rooms, offices for the clerk, waiting rooms, &c. There are also several spare rooms on the second floor. To the free library there are on the ground floor lending and reference libraries, and above them is a large reading-room with a handsome open timber roof, of hammer-beam construction. At the back are extensive stabling, cart sheds, fire-engine house, &c. The contract for the bulk of the work was taken by Mr. Charles Steel, of Pitsford-street, Birmingham. The windows have been filled with rough tinted quarry glass by Messrs. Camm Brothers, of Birmingham, and Mr. Roddis, of Birmingham, has executed the carving. Mr. Wm. Peacey acted as clerk of Works.

CHURCH OF ST. JOHN THE EVANGELIST, MOLD, FLINTSHIRE.

THIS church, which is intended to be used as a chapel-of-ease of the parish church, for the accommodation of the Welsh-speaking portion of the population, is being erected on a site near the centre of this ancient border town. As will be seen from the view, the east end of the building is to the road, and for this reason the tower and spire have been placed on the north side at this end. The details of the structure throughout are of a plain and simple character. The outside walling is of local stone, of a buff colour, used in random courses; red Helysly is being used for all the dressings. The interior, which consists of nave, chancel, vestry, and organ chamber, is lined throughout with white pressed bricks, no plaster being used on any of the walls. The roofs are of red deal, stained, and the seats, the ends of which are square-framed, are to be of pitch-pine, varnished. Brown Italian tiles are to be used for covering the roofs. The present contract, which is let for a little over £2,000, includes building up the tower to the height of vestry ceiling. A sepa-

rate contract has been entered into for finishing the tower and spire. Accommodation is provided for 290 people. The contractor is Mr. Charles Holland, of Chester, who is carrying out the work from the designs and under the superintendence of Mr. John Douglas, also of Chester.

HOUSES AT MANCHESTER AND NORTHAMPTON.

A CORRESPONDENT has forwarded the sketches we publish of two houses—one erected at Northampton, from the design of Mr. E. W. Godwin, F.S.A., the other at Manchester, by Messrs. M. and H. Taylor. The house at Northampton was erected long before the one at Manchester, and was illustrated some time since in another journal.

DANGERS OF CREOSOTING TIMBER.

AN inquest concerning the death of Abraham John Roberts, who was killed by the falling of a timberstage at Norton's timber-yard, Wharf-road, City-road, was concluded on the 8th inst. Mr. Robert Walker, district surveyor of St. Martin's-in-the-Fields and St. Anne's, Soho, deposed that he had examined the pillars that supported the timber. In his opinion the accident was caused by the giving way of the centre post. The cause of the fracture of the post was that, although, from outward signs, it appeared to be perfectly sound, it was quite rotten in the centre. Its rotten condition was due to its having been creosoted. This process caused timber to be hermetically sealed, and thus the juice of the wood was not allowed to pass off, and rotteness in the centre was the unavoidable result. In answer to a question, Mr. Walker said that it had been found by experience that the process of creosoting was a failure, and that it worked great damage inside. It was not generally known that the process had a tendency to cause the interior part of the timber to decay. Mr. Bridgeman, the surveyor appointed by the coroner, said he had also examined the scene of the accident, and was of opinion that it had been caused by the fracture of the centre post, and that the fracture took place in consequence of the timber-stage being overloaded. There was a weight of 18 tons on the centre post at the time of the accident, while on the other two posts there was a weight of 9 tons each. It was undoubtedly the hollow condition of the centre post that caused it to give way. The condition of the post was such that the slightest vibration would be enough to cause it to break and bring the whole of the timber down without a moment's warning. The case was an exceptional one, and should be sounded as a warning note to other proprietors of timber-yards in order that they might use precautions against such an accident occurring in connection with their own property. The sad occurrence was no doubt purely accidental, but it was advisable that Messrs. Norton should take care in the future to guard against mishaps of the kind, as the same extenuating circumstances possibly could not be applied in another case. In answer to questions by the foreman of the jury, both of the surveyors admitted that, considering the exterior appearance of the supports of the timber stage, they should not have condemned them as unsafe had they seen them before the accident occurred. The jury returned a verdict of "Accidental death," but appended to it an expression of their opinion that "all supporting posts on the estate should be examined by a surveyor, and be repaired or removed as may seem necessary for the safety of all the men employed thereon."

The rebuilding of Vale-street Chapel, Wrexham, which had to be taken down on account of defects in the walls, is proceeding. Mr. Williams, the sub-contractor, brought his men over last week, the Wrexham Advertiser states, and took forcible possession of the place, and proceeded to lock up the tools of the men in the employ of the contractor, Mr. Hughes, and they were kept standing idle several days. An application has been made to the Master of the Rolls by Mr. Hughes, to regain possession of the building, in order that he may complete it, the sub-contractor having, it is alleged, broken the contract by drawing off his own men when the architect had condemned the work, which indeed was coming down, and had to be propped up.

Works of sewerage are being carried out for the Cannock Local Board; No. 1 contract has been taken by Mr. Clark, and No. 2 by Mr. Roberts, who has just commenced operations.

LIGHT AND AIR.*

By JAS. BALL.

FOR the full and proper enjoyment of immovable property, certain rights are necessary which come over or are connected with adjoining property. Thus, if a man have a field environed on all sides by the property of others, he clearly must have a right to go over the property of those others, in order to get to his own, or his property would be useless to him. Rights of this character are called easements: and among these rights are those which a man has to light and air coming over adjoining property to his own. These rights are founded almost exclusively upon customary usage—or, as it is termed, prescription—and formerly their protection and continuance depended mainly upon the establishment of custom, according to the old formula, from time whereof the memory of man runneth not to the contrary. Now, however, by 2 and 3 Will. IV. c. 71 (an Act for shortening the time of prescription in certain cases) it is enacted, by sec. 3: "That when the access and use of light to and for any dwelling-house, workshop, or other building, shall have been actually enjoyed therewith for the full period of twenty years without interruption, the right thereto shall be deemed absolute and indefeasible, any local usage or custom to the contrary notwithstanding, unless it shall appear that the same was enjoyed by some consent or agreement expressly made or given for that purpose by deed or writing." This applies only to light, it will be seen; and it has been held that, so far as light is concerned, this enactment destroys the custom of the City of London by which right to enjoy light and air might formerly in certain cases have been infringed, without any liability to make good damage caused by the infringement. Formerly in London, when rebuilding upon old sites, the new buildings might be carried to any height, notwithstanding an increase in height might interfere with the light formerly enjoyed by the adjoining property; but now London is subject to the general law, and light may no more be infringed there than in any other places. This has given rise to many lawsuits; indeed, there is scarcely any rebuilding in the City which is not menaced by a lawsuit, so valuable is the light there, and so thickly packed together the buildings.

The building or tenement in respect of which an easement is claimed or enjoyed, is called, by way of distinction, the dominant tenement, and that over which the easement passes is called the servient tenement: and it is a principle of the law as to easements, that the owner of the dominant tenement may not increase the burden of the servient tenement. It will be necessary to bear this in mind in our consideration of the present subject.

Before proceeding further, however, let us point out an important distinction which exists between the right to light and the right to air, notwithstanding that frequently they are treated as one and the same. In the case of the "City of London Brewery Company v. Tennant" (L.R. 9 Ch. 212) Selborne L.C. thus laid down the distinction. He said: "I observe that a formula has crept in . . . in which air is coupled with light. Now, the nature of the case that would have to be made for an injunction by reason of the obstruction of air is *toto cælo* different from the case which has to be made for an injunction in respect of light. It is only in very rare and special cases, involving danger to health, or at least something very nearly approaching to it, that the court would be justified in interfering on the ground of diminution of air." And then he adds a caution worth remembering: "Therefore, when witnesses say that there is a material diminution of light and air, and say no more, they are in truth reducing the value of their evidence as to light to the standard which must be applied to their evidence as to air, as to which such evidence is of no value whatever." This, of course, proceeds from the natural difference between light and air; as, for example, the rays of light always travelling in straight lines, and

the air following a distinct law of motion; so that an erection which would prevent the progress of the straight rays of light, and thus obstruct light, would not necessarily be an obstruction of air also.

Practically, therefore, all that can in most cases be complained of is the obstruction of light; and it will be found that most of the cases bearing upon our subject relate really only to light.

Extent of the Right.—In "Kelk v. Pearson" (L.R. 6 Ch. 890) James L.J. defined the extent of the right. He said: "The Statute [2 and 3 Will. IV. c. 71, s. 3, above quoted] has in no degree whatever altered the pre-existing law as to the nature and extent of this right. The nature and extent of the right before that Statute was to have that amount of light through the windows of a house which was sufficient, according to the ordinary notions of mankind, for the comfortable use and enjoyment of that house, if it were a dwelling-house, or for the beneficial use and occupation of the house, if it were a warehouse, a shop, or other place of business. That was the extent of the easement—a right to prevent your neighbour from building upon his land so as to obstruct the access of light and air, to such an extent as to render the house substantially less comfortable and enjoyable." In a prior case "Clarke v. Clark" (L.R. 1 Ch. 16) Cranworth L.C. had held that in cases of the obstruction of ancient lights, the real question is, not what is, scientifically estimated, the amount of light intercepted; but whether the light is so obstructed as to cause material inconvenience to the occupiers of the house in the ordinary occupations of life. And Lord St. Leonards, in his well-known Handy Book, says: "Wherever it is shown that the comfort or enjoyment of a man or his family in the occupation of his house is seriously interfered with, and still more, where he is prevented from carrying on his business with the same degree of convenience and advantage as theretofore, by reason of the obstruction of light caused by his neighbour's new building, there is sufficient ground for the interference of a court of equity." The mere invasion of privacy, however, by the building of premises which overlook one's house, but do not affect its lights, is no ground for the interference of the Court.

The Rule as to Forty-five Degrees.—There appears to have grown up some kind of idea, never clearly understood by anybody, as to forty-five degrees, with regard to the right to and obstruction of light. That notion was happily put into shape and explained by Selborne L.C. in the above quoted case of the "City of London Brewery Company v. Tennant," in which he said: "With regard to forty-five degrees there is no positive rule of law upon that subject; the circumstance that forty-five degrees are left unobstructed being merely an element in the question of fact whether the access of light is unduly interfered with; but undoubtedly there is ground for saying that if the legislature, when making general regulations as to buildings, considered that when new buildings are erected the light sufficient for the comfortable occupation of them will, as a general rule, be obtained if, the buildings to be erected opposite to them have not a greater angular elevation than forty-five degrees, the fact that forty-five degrees of sky are left unobstructed may, under ordinary circumstances, be considered *prima facie* evidence that there is not likely to be material injury; and, of course, that evidence applies more strongly where only a lateral light is partially affected and all the lights are not obstructed. I make that observation, not imagining that either at law or in this court any judge has ever meant to lay down as a general proposition that there can be no material injury to light if forty-five degrees of sky are left open; but I am of opinion that if forty-five degrees are left, this is some *prima facie* evidence of the light not being obstructed to such an extent as to call for the interference of the court—evidence which requires to be rebutted by direct evidence of injury and not by the mere exhibition of models." His lordship's words are so full and explanatory that nothing need be added to them upon this point; but the case of "Hackett v. Baiss" (L.R. 20 Eq. 494) may be referred to by the reader, in which case the Master of the Rolls followed the rule or reasoning laid down by the Lord Chancellor; and the case of "Theed v. Debenham" (L.R. 2 C.D. 165) further illustrates the point.

Remedies.—The remedies of a person aggrieved

by an invasion, or threatened invasion of his right to light or air are three-fold: (a) action for damages; (b) injunction to prevent invasion; (c) mandatory injunction.*

a. Action for Damages.—Where damages only are sought, the common and most convenient course is to proceed by action in one of the Common Law Divisions: and where the damage sustained by the obstruction of light or air can be easily and readily ascertained, this is recognised to be the proper course to pursue, and in such a case an injunction would most probably be refused. The remedy by injunction is intended mainly to meet those cases in which the amount of damage cannot be easily and readily ascertained.

It should be noted that in most cases, the fact of a plaintiff having recovered damages on an obstruction of light or air, does not condone the offence of the obstruction; and the plaintiff, or other person aggrieved, may go on bringing actions and recover damages in respect of the damage accruing from time to time by the diminution of light or air. The course which should be adopted, therefore, when the plaintiff has succeeded in proving himself damaged, is to make an arrangement with him, so as to compensate him for the damage sustained and to be sustained, and thus bar future actions.

In case an action for damages only be brought, the following is the form of endorsement on the writ:—

"The plaintiff's claim is for damages for obstructing the access of light [and air (†)] to the plaintiff's house."

b. Injunction to Prevent Invasion.—In cases where it is sought to restrain a threatened invasion of a right to light and air or either, a motion should be made in the Chancery Division for an injunction. The Chancery Division may also award damages. By 21 and 22 Vict. c. 27, provision is made for this, and sec. 2 is as follows:—"In all cases in which the Court of Chancery has jurisdiction to entertain an application for an injunction against a breach of any covenant, contract, or agreement, or against the commission or continuance of any wrongful act, or for the specific performance of any covenant, contract, or agreement, it shall be lawful for the same court, if it shall think fit, to award damages to the party injured, either in addition to or in substitution for such injunction or specific performance, and such damages may be assessed in such manner as the court shall direct."

c. Mandatory Injunction.—A mandatory injunction is a remedy granted in rare cases, by which one who has invaded the right to light or air, is compelled to take down the buildings by which the light or air is obstructed.

The following decisions and remarks should be attentively considered, as touching the various remedies for invasion of right to light and air, which we have just enumerated.

In the case of the "Curriers' Company v. Corbett" (4 De Gex, J. & S. 764) Turner L.J. held that "it is not every impediment to the access of light or air which will warrant the interference of the court by way of injunction, or even entitle the party alleging himself to be injured, to damages at law. In order to found a title to relief in equity, or even at law, in respect of such an impediment, some material or substantial injury must be established, and the onus of proving the injury must rest, of course, on the plaintiff." This decision points out the fact that in some cases there may be ground for an action for damages, although there may not be ground for an injunction. Westbury L.C. pointed out very clearly the distinctive remedies, and the reasons for them, in two cases which came before him on appeal. In one of these, "Jackson v. Duke of Newcastle" (3 De Gex & C. 275), he said: "Where the darkening of the ancient windows of a dwelling-house materially injured the comfort of the existence of those who dwell in it, the court would interfere by injunction."

Upon a similar principle, where the obstruction of the ancient lights of a manufactory or of business premises renders the buildings to a material extent less suitable for the business carried on in them, it is a case for injunc-

* To these remedies is added that, which a man has (according to Blackstone) to enter into adjoining premises and peacefully pull down any erection put up thereon, which interferes with his ancient lights: a remedy, it need hardly be said, seldom resorted to in these times.

† See the case of "City of London Brewery v. Tennant," cited at page 31, and note what the Lord Chancellors said to the association of light and air.

* This article was published in 1877 in a series of "Popular Monthly Law Tracts," edited by Mr. Jas. Ball, author of "The Popular Conveyancer," &c. The series was favourably noticed in our own and other journals and soon ran out of print. The author has had several applications to reprint this article, which formed No. 3 of the series, but, believing that the information would be more widely extended if published in our pages, has offered us the right of publication, of which we have availed ourselves.—Ed.

tion, and not merely for compensation in damages. The foundation of the jurisdiction [of the court to grant an injunction] appears to be that injury to property which renders it in a material degree unsuitable for the purposes to which it is now applied, or lessens considerably the enjoyment which the owner now has of it. The court considers that injury of this nature does not admit of being measured and redressed by damages.* And in the other case, *Isenberg v. East India House Estate Company Limited* (3 De Gex &c. 263), his Lordship said: "The common law remedy for a grievance of this description [i.e. invasion of right to light or air] is an action for damages: an action liable to be resorted to as long as the cause of damage continues. Upon that ground, and by reason also of the damage in many cases not admitting of being estimated in money, this court [the Court of Chancery] has assumed jurisdiction."

"The jurisdiction of this court, so far as it partakes of the nature of a preventive remedy, that is, prohibition of further damage, or an intended damage, is a jurisdiction that may be exercised without difficulty, and rests upon the clearest principles. But there has been superadded to that the power of the court to grant what has been denominated a mandatory injunction, that is, an order compelling a defendant to restore things to the condition in which they were at the time when the plaintiff's complaint was made. The exercise of that power is one that must be attended with the greatest possible caution. I think, without intending to lay down any rule, that it is confined to cases where the injury done to the plaintiff cannot be estimated and sufficiently compensated by a pecuniary sum. Where it admits of being so estimated, and where the evil sustained by the plaintiff may be abundantly compensated in money, there appears to me to be no necessity to superadd the exercise of that extraordinary power by this court." His lordship, in the latter decision, very concisely states the three-fold remedy against the invasion of right to light and air, and it would be gathered from the opinion expressed by him that the court would be chary of granting a mandatory injunction, but for later decisions, to which we shall presently refer.* *Turner L.J.*, in the case of the *"Currier's Company v. Corbett"* (cited at p. 39) seemed to consider it necessary to put the jurisdiction of the court to grant a mandatory injunction as a hypothesis. He said: "Assuming this court has jurisdiction to order a building, which, so far as it can impede the progress of light and air, has been actually completed, to be pulled down—a jurisdiction which, so far as I am aware, has never been assumed or exercised—this Bill seeks no more than a preventive remedy, and there can be no case for prevention where what is asked to be prevented has been actually done." The latter part of the last-quoted decision will serve as a hint to the draftsman to ask enough, and not, where a mandatory injunction is sought, to merely ask for an injunction to restrain further obstruction to light or air.

The power and the willingness of the court to grant mandatory injunctions are, however, demonstrated by some more recent decisions. In *"Senior v. Pawson"* (L.R. 3 Eq. 333) Wood V.C. said he had no doubt as to the jurisdiction of the court to order buildings to be pulled down; although in the case before him he directed an inquiry as to damages, instead of granting a mandatory injunction. In *"Beadel v. Perry"* (L.R. 3 Eq. 465), a case in which a mandatory injunction was granted, Stuart V.C. also gave some idea of what the court considered a ground for its interference. He said, "It seems to me that where, opposite to ancient lights, a wall is built not higher than the distance between that wall and the ancient lights, there cannot, under ordinary circumstances, be such a material obscuration of the ancient lights as to make it necessary for this court to interfere by way of injunction. . . . It has been clearly proved in this case that, opposite to the plaintiffs' ancient lights, the defendant has built a wall very much higher than the distance between them and the wall, and to that extent the defendant must, in my opinion, take his wall down. There must be a mandatory injunction to that effect." In the case of *"Lady Stanley of Alderley v. Earl of Shrewsbury"* (L.R. 19 Eq. 616) the court directed an inquiry as to damages instead

of granting a mandatory injunction, being of opinion that it could not in that case grant the latter remedy. In the case of *"Smith v. Smith"* (L.R. 20 Eq. 500) Jessel M.R. made some remarks concerning mandatory injunctions, to the effect that the court might grant them as unreservedly as others, and need exercise no more caution in doing so than in giving other remedies; and in that case he granted a mandatory injunction, not to be put in force for two months. It will thus be seen that whatever difficulty the court may have experienced in former times, as to granting the extreme remedy of a mandatory injunction compelling the offending party to pull the obstructive building down, no such difficulty is recognised now; although the leaving of the court still is to grant an inquiry as to damages under Lord Cairns' Act* instead.

In the case of the *"City of London Brewery Company v. Tennant"* (cited at p. 34), James L.J. said: "In all these cases as to light and air the Court of Equity is not administering any equitable relief strictly so called; but is giving an equitable remedy for the violation of a legal right: and the question before a Court of Equity in all these cases is substantially the same question as that which would have to be determined by a jury, under proper directions by a judge as to the principles of law applicable to the case."

Future Damage.—It frequently happens upon an obstruction of light that the amount of damage caused thereby depends upon the nature of the business carried on upon the premises injured; so that a slight diminution of light might cause but little or no inconvenience in some cases, whilst it would be a serious inconvenience in others. Therefore the question has arisen whether the Court, in dealing with the amount of damages where the present injury is small, has power to take into consideration possible injury of a greater extent in the future, upon a change of circumstances. The question does not appear, however, to have been settled until recently; and so far as the older reported cases show, it seems that the Court formerly considered it must deal with the present damage only, and not consider any possible future damage. In the case of *"Jackson v. Duke of Newcastle"*† *Westbury L.C.* said he had been unable to find any authority for taking possible future damage into consideration. But in the more recent case of *"Aynsley v. Glover"* (L.R. 18 Eq. 544) Jessel M.R. held otherwise and said that the Court is bound to consider the use to which the property the light of which is obstructed may be put. His decision was confirmed on appeal (L.R. 10 Ch. 283) when it was also held that where the ancient lights have been enlarged, the plaintiff should not be compelled to reduce the windows to their former size as a condition of obtaining an injunction.

Reserving Right to Light and Air.—Where the owner of property sells a portion of it, and wishes to reserve the easements of light and air to that he retains, he should so reserve them by the deed of conveyance of the portion sold. In the case of *"Ellis v. Manchester Carriage Company"* (L.R. 2 C.P.D. 13) it was held, following several previous decisions, that if a person having a house on his land the windows of which have existed for more than twenty years, sells a portion of the land, the purchaser may erect any buildings he pleases upon the land so sold to him, however much they may interfere with the light coming to the windows of the vendor's house, unless the conveyance by the vendor to the purchaser should have reserved to the vendor the easement of light to the house retained by him. The justice of this decision is apparent, although it appears at the first blush to be against the principle of the Prescription Act, which makes twenty years' enjoyment of light the base of an indefeasible right. But, as we shall have occasion hereafter more fully to remark, unity of possession of the easement and the land over which it comes, is a bar to the running of the twenty years, and the enjoyment during the unity of possession is, in fact, no easement at all, being but the user by the owner of his own property. Besides which, if the purchaser might not build on the land purchased by him from the owner of an adjoining house, for fear of obstructing his light, the land purchased would be less valuable to him on that account, and that would be a consideration which ought to be provided for in the deed of conveyance to him.

* 21 & 22 Vict. c. 27, cited at page 37.

† Cited at page 38.

A proviso has been inserted in some modern Crown leases against the acquirement by the lessees of any right to light or air. It is as follows:—

"Provided always and it is hereby agreed and declared and this demise is made upon the express condition that the lessee his executors administrators and assigns shall not by virtue or in respect of this demise be deemed to have acquired or be entitled to nor shall he or they during the existence of the term hereby granted acquire or become entitled to by length of enjoyment prescription or any other means whatsoever in respect of the hereby demised premises any right of air or light or other easement from or over or affecting any lands or hereditaments belonging to the lessor his heirs or assigns not comprised in this demise. But on the contrary it is agreed and declared that it shall be lawful for the lessors his heirs or assigns and his and their grantees lessees and tenants or any of them at all times hereafter to erect any new building or buildings of any height, or on any land belonging to the lessor his heirs or assigns not included in this demise and to raise to any height or alter any building now existing or to be hereafter erected upon any such land whether any such buildings or alterations shall or may or shall not or may not prevent obstruct or affect in any way the passage of air or light to the premises hereby demised or any part thereof or to any new building which may hereafter be erected upon the land hereby demised."

This proviso is perhaps calculated to prevent a fruitful source of litigation; but lessees should consider, before accepting such a proviso, how seriously the curtailment of their right to the easements of light and air, made possible by it, may affect them.

Unfinished Houses.—It is not a necessary condition to the acquiring of the right to light under the Act of 2 and 3 Will. IV. c. 71* that the house in respect of which light is claimed should be occupied, or even in a finished state, during the twenty years prescribed by the Act for the attainment of the right. If there are windows in the house through which light may pass which would be available for the comfort and enjoyment of the inmates if it were occupied, that is sufficient. This was so held in the case of *"Courtauld v. Legh"* (L.R. 4 Ex. 126) in which Kelly C.B. said: "I am of opinion that no occupation at all, in the sense of personal occupation, is necessary to constitute actual enjoyment within the meaning of the statute. It appears that this house was completed as to its external and internal walls, the roof, and the floorings; and that windows had been put in, capable (as we may suppose) of being opened and shut, and of admitting light. When a house is in that condition, it may properly be said that the owner enjoys the use and access of light to it, and such enjoyment is sufficient to give a prescriptive title under the Act." Channell B., Pigott B., and Cleasby B., concurred in the decision.

Unity of Possession.—Upon the principle that one cannot enjoy an easement coming over land who has that land itself† and upon the further principle that the accruing right to the easement of light is suspended, but only suspended, during unity of possession; it has been held that the twenty years, prescribed by sec. 3 of 2 and 3 Will. IV. c. 71, as the period of enjoyment necessary to give title to the easement of light, must be twenty years during which there has been no unity of possession of the property whose light is sought to be protected, and that over which the easement of light comes; but that it need not have been twenty years' continued enjoyment. *Hatherley L.C.* applied these principles in the case of *"Ladyman v. Grave"* (L.R. 6 Ch. 763), in which he thus illustrated the rule drawn from them; he said, "If it had been shown that the enjoyment had lasted for fifteen years and upwards, and then there had been an interruption by unity of possession, and then the enjoyment had lasted for five years more without the unity of possession, in such a case an enjoyment for twenty years could have been pleaded." His lordship held also that when the plaintiff had shown his right to the easement of light, the

* Cited at page 33.

† An easement is an accommodation or convenience, which one has or claims over the property of another, for the enjoyment of one's own property, such as a right of way, watercourse, light, &c.; so that is evident, from the meaning of the term, that one cannot have an easement over one's own land.

* See particularly *"Smith v. Smith,"* cited at page 49.

ons of proving a unity of possession which destroyed that right rested upon the defendant.

Summary.—We thus have seen that:—

The right to light and the right to air are easements which one man has coming over the property of another to his own; and that these easements are distinct.

Twenty years' enjoyment of the easement of light gives a prescriptive right to it: in the absence of agreement to the contrary.

Obstruction of light, which interferes materially with the comfort and convenience of those affected by it, is an offence which the court is prompt to remedy; but injury to health or other serious effect is considered a necessary ground for the interference of the court in cases of diminution of air.

Possible future damage is now taken into account as well as present damage.

Vendors should reserve to themselves the easement of light when selling land adjoining their house property, in order to secure light to their houses.

The right to the easement of light accrues in respect of unfinished or unoccupied houses, which have windows capable of receiving light during the twenty years of prescription.

There must be no unity of possession of the easement of light and the land over which it comes, during the twenty years' enjoyment of the easement upon which the prescriptive right depends; but unity of possession only suspends the prescription during the unity, and does not destroy or make unavailing the enjoyment of the right before the unity.

Concluding Remarks.—We have thus briefly set before the reader the subject of light and air, and the rights to their use as easements. With regard to light, especially, we may remark that the right to it claimed by various persons upon the removal of old buildings and the erection of new buildings in place of them, has given rise to endless litigation. If the property be large, or affects a large number of surrounding owners, there is almost invariably a dispute about the light: as often as not a dispute raked up for the mere purpose of endeavouring to extort "compensation" by the threat of proceedings. Many writers have adverted to this* and have shown how that owners have had to fight their way to new buildings through expensive litigation: and how, on the other hand, others have spent and lost more in seeking to protect a light than the whole property in respect of which they claimed was worth. Those who find themselves in the position of adviser upon such questions should therefore be more than ordinarily careful; and, we think, should always endeavour to arrange a fair compromise rather than advise litigation. There are well-known instances in which large sacrifices of space have been made in new buildings, because of the right to the light passing through some trumpery little window being set up as a pretext for claiming exorbitant compensation. In all such cases a spirit of liberality should instead be shown: the party whose light will be affected should be willing to receive, and the party proposing to obstruct the light should be willing to pay, a fair equivalent for the light: and it is a disgrace to anything like neighbourliness that so much litigation should be rife as there is in respect of these matters. Easements are so emphatically the concern of neighbours that the law cannot possibly lay down rules which shall comprehend every case: if, therefore, neighbours disagree, they are almost compelled to indulge in litigation and resort to courts of law to have their differences healed. If, however, they are wise, they will be content with a more simple, far less expensive, and eminently good-natured remedy, which is known by the name of "amicable arrangement"; the taking of which they will consequently find to be marked by a saving of time, temper, and money.

Still there are some cases in which litigation must, it would seem, inevitably arise: and we may make a closing suggestion, founded upon the principles of the decisions, as to the evidence to be adduced in support of them. When the obstructive building is already erected, the evidence of persons occupying the premises whose light is obstructed should be obtained, as this will have far greater weight than any scientific theoretical evidence; and the latter will not have

much weight, even though supported by the exhibition of models, compared to the former. But if the buildings are only in course of erection, and there be only a threatened invasion, models should be exhibited to the court, and scientific theoretical evidence given as to the result which would follow from the erection of the proposed buildings.

WOOD PRESERVING BY CREOSOTE.

IN the proceedings of the Engineers' Club at Philadelphia, some useful observations are recorded on timber creosoting to which we refer. Decay is mainly attributable to the fermentation of the albumen of the sap, which commences when heat and moisture are present; and the aim of all wood-preserving processes is to prevent this fermentation by coagulating the albumen of the sap. Various methods for effecting this, known as the chloride of zinc (Burnettizing); corrosive sublimate or kyanising; sulphate of copper (Boucherie's), and other processes of saturation with metallic solutions may be named; but Mr. E. R. Andrews, of Boston, remarks they only retard decomposition by acting chemically upon the albumen, but they will in time redissolve and be washed out by the rain. They do not protect the fibre itself. On the other hand, Mr. Andrews contends that creosoting does more than metallic salts to coagulate the albumen; it forms a protection to the fibre. Being insoluble in water, the creosote oil enters the pores of the wood and clothes the fibres with an impenetrable coating. Mr. Hayford's process differs essentially from the well-known Bethell's process, inasmuch that the latter can only be applied to seasoned timber, while by the Hayford method green wood is preferred. The reason given by the author for this preference is that the more nearly the condition of timber is to that of a living tree, the sap being withdrawn from the pores, the more readily it will absorb oil. We may quote Mr. Andrews' description of the process here:—"To withdraw the sap and moisture without hardening the fibres is the first step in the Hayford process. This is effected by means of steam, heat, and air-pressure. The wood is loaded on iron cars, and run into a strong iron cylinder which is then hermetically closed. Steam is then pressed through a long coil in the bottom of the cylinder, and also, to a certain extent, free steam is admitted into the cylinder itself. But steam alone would not heat the wood sufficiently to vapourise the sap. . . . To secure a greater degree of heat, by means of a powerful air-pump worked by steam, atmospheric air is pumped into the cylinder until the gauge shows a pressure of 30 or 40 lb. to the square inch. Thus a double result is obtained, i.e., a temperature of 240° to 250°, and also this pressure upon the surface of the wood tends to counteract the tendency of the wood to crack in consequence of expansion of the moisture within. . . . Experience alone will determine when the wood has been subjected to the steaming process long enough to heat the wood to a point when the sap and water will vapourise. Then by closing one set of valves and opening others, the air-pump becomes a vacuum pump, by which the vapours are withdrawn from the cylinder and the wood. The wood parts with its moisture to such an extent, that several hours' work of the pump are needed to produce a vacuum of 24 inches, whereas without steaming the wood, the same vacuum would be reached in half-an-hour." We see from this account that the timber is deprived of all its sap and moisture, and remains in a

vacuum with its pores open ready to imbibe the oil which is now admitted, having been first heated to 200° F. "The oil enters through perforated pipes by which every stick is at once bathed with oil which is rapidly absorbed. When the cylinder is full, the contents are subjected to a pressure of 100 lb. to one square inch until the wood has absorbed the requisite quantity." Mr. Andrews then adduces evidence to show that if the process is thoroughly performed, creosoted wood is practically imperishable. In the Philadelphia and central railroads, creosoted pine ties were laid in the road bed in 1875, and are now in capital condition. In the late railways of Belgium the use of creosoted ties has proved a great success, according to C. Coisue, the superintendent of the creosoting establishment. His figures show that in some cases they have stood from 16 to 21 years in use. To come nearer home, the author quotes the experience of Mr. Harrison, the chief engineer to the North Eastern Railway, who mentions one sample of a Scotch fir sleeper, creosoted, which had been laid down near Tweedmouth in 1858, thus having been 20 years in use. It was an average specimen, and was still in good condition, having been run over by all the trains between London and Edinburgh. The sample showed no indentation under the rail. Against the ravages of the teredo, creosote oil has been long acknowledged a protection to piles and submarine timber work. Various specimens of railway sleepers were exhibited by the author, which had been in use 12 to 20 years, and some blocks that showed a partial riddling which had been submerged in salt water after a portion only had been creosoted. Added to other evidence we have before adduced in this journal, the above experience clearly points to the value of thorough oil impregnation.

TITLES TO LAND.

WE have a pamphlet before us bearing the above title, in which the authors, Messrs. Renton and Co., estate and insurance agents, of Manchester, propose certain well-timed suggestions for the simplification and registration of titles to land. These suggestions are made in view of the reappointment of a Committee by the House of Commons to inquire and report whether any and what steps should be taken with the above object in view, and to facilitate the transfer of and to prevent frauds on purchases and mortgages of land. No one who has had any experience in the purchase of property, whether houses or lands, must not have deplored the unnecessary length of deeds, the prolix narration of covenants and prior-titles, and the unintelligible phraseology employed. One of the suggestions we cordially agree with—it is the cutting short of puzzling descriptions of lands, and the resort to tracings of the Ordnance survey. The author suggests if a certain property came to be conveyed, "the Ordnance survey be referred to, and if it were on too small a scale to show distinctly and with precision the subjects referred to, let the scales be enlarged and a tracing of the subjects laid down on the conveyance. That tracing would not require to be repeated, as we will show hereafter, on any subsequent transaction of the property." It is proposed that in every town or district there should be national or statutory landmarks, or *data* points, so that the chief measurements to be set forth on the tracing would be, say, the distance of the north boundary of No. So-and-So-street, from that mark or point. That distance having been determined, and the point fixed, there could be no question hereafter as to the position of that boundary, and relatively to the other boundaries of the subjects. Thus, all lands by this suggestion would be identified by a tracing or plan made and engrossed on the title. In speaking of covenants or conditions under which land is held, the authors distinguish the cases that occur. They say:—"As to the conditions in existing titles which are repeated *ad nauseam* in every transfer, these may be of the following descriptions:—1. Those which, if not complied with, may either cause the estate to revert to the original grantor or his representatives, or subject the holder in payment of a penalty or liability for damages. 2. Those which have been obviated by other circumstances. 3. Those which infer no penalty if not complied with." In the first of these cases it is observed to be quite unnecessary to engross these conditions in every transfer,

* See particularly the finely written preface by the late David Gibbons to the fifth edition of "Gale on Easements," edited by him.

but "that a proper reference be made to them in the transfer, as they are set forth in the title which created them, and in that way they will be incorporated in the transfer, and binding." If the title be in a dilapidated state, a true copy made of it, and attested and referred to, that will serve once for all. These two suggestions, if adopted, would, we consider, wonderfully shorten transfers, and confer a lasting boon on granters and grantees. We have no space here to allude to the other covenants under which real estate may be conveyed to new holders, though, as the authors justly contend, it is absurd that in every building estate being laid out every title to a separate lot of ground—it may be a hundred—be set forth *ad longam*, when the conditions may be the same, or different only in one or two special cases. Of course, it is necessary to have general conditions prepared by the proprietor of the estate, which should be made the basis for grants of title. If altered conditions are to be introduced in the title these can be set forth as exceptional; but it certainly seems ridiculous to repeat those common and general conditions which universally apply. The best mode unquestionably would be to make such general conditions statutory, under which all titles would be granted. A similar mode may be adopted with mortgages. The authors give various forms for transfers of land under particular conditions, and to these, and other suggestions as to registration, we have much pleasure in referring our readers who are interested in divesting legal documents of their present complexity and cost. The machinery of the law is still most cumbersome, and Messrs. Renton will have done some good if, by the timely publication of their suggestions, a simplification of titles can be procured.

COMPETITIONS.

CITY OF LONDON SCHOOLS.—The designs for the new school buildings which are to be erected on the Thames Embankment are still under consideration, and, notwithstanding the Easter recess, the Court has been actively engaged in examining the several plans. We understand that the members are much pleased with several of the plans submitted, and that an award may speedily be looked for. No professional referee has as yet been retained, though possibly the Court may seek professional confirmation of their decision. It is a question yet to be determined as to whether the competition plans will be exhibited or not. We hope both the latter proposals will be carried out, in common fairness to the competitors.

HALIFAX.—The Halifax School Board have decided not to adopt any of the plans submitted in competition for the new higher Board School, none being considered of sufficient merit. This result has been arrived at after calling in Mr. Robson, the architect of the London School Board, to report on the plans.

IPSWICH PUBLIC HALL COMPETITION.—Last week we mentioned the result of the competition for the alteration of the Public Hall, Ipswich, which has given rise to some discussion. Having seen the plans sent in, under the motto "Tria Juneta in Uno," by Mr. H. Cheston, of London, and also the hall in Westgate-street, we are in a better position to speak of the practicability of the scheme. The present hall is a brick-built structure 98 feet long by 50 wide, with a recess for orchestra at one end, and a gallery at the entrance end, which returns for a short distance in a curvilinear form round the sides. The walls are relieved by pilasters, above which is a series of clerestory or lunette lights that pierce the coved ceiling and form groined pendentives between. These admit the light. The flat portion of ceiling is relieved by elliptical-shaped panels, which were formerly intended to be glazed. Mr. Cheston's premiated plan shows an extension southward, making the hall 151 feet long, and the removal of the saloon and other apartments in the rear. He forms an elliptical alcove or recess at the end, and fills the present panels in the ceiling with glazed lanterns. The question is whether this extension, at an estimated cost of £4,500, is the best means of providing for the requirements of the Corn Exchange; in other words, whether the expenditure of this sum will give the town what it wants, equally well with a more costly proposal of building a new Corn Exchange, at the cost of £24,000 on another site. Of course

there are two considerations in such a question, one of means, and the other of efficiency; but we are disposed to think, from an examination of the plan, that the hall will be spoilt for public audiences by the disproportionate length of the room, and also that a wider and more concentrated area would be better secured for a Corn exchange. Unless the hall can be widened as well as lengthened, we are afraid the building will assume the character of a gallery—a kind of *tertium quid* not to be desired.

KENILWORTH.—The first premium of £50 has been awarded by the Local Board of *Kenilworth*, not Cardiff, as stated by us last week, to Mr. G. A. Lundie, M.I.C.E., for his scheme for the sewerage of the town. It is proposed to deal with the sewage on eight acres of land by intermittent downward filtration, and the whole of the works are estimated to cost about £5,000. The Local Board advertised for plans, specifications, and tenders, and there were twenty competitors.

SCHOOLS OF ART.

GLOUCESTER SCIENCE AND ART SOCIETY.—The annual report of this society states that during the past year a piece of garden ground on the north side of the schools has been purchased for £750, in view of a possible extension of the institution, and also to prevent the erection of objectionable buildings close to the schools. The work of the Science school commenced on October 10th, 1877. Four students were enrolled, and 52 presented themselves for examination. The results were hardly so good as last year, though as this appears to be the case throughout the country, it may be assumed that the standard of examination has been raised. In the Art school 229 students attended the various classes throughout the year. 559 works in various stages by 78 students were sent to South Kensington in April for examination. In the National Competition the school obtained one bronze medal and two book prizes. In the advanced Art examination, held in June last, out of 54 candidates 5 were successful, and 3 received prizes.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

GLASGOW ARCHITECTURAL ASSOCIATION.—The opening meeting of the second session of this association was held last week. Mr. James Sellars, I.A., hon. president, who entertained the members, received them in the entrance hall, where the drawings which have been submitted in competition for the gold medal and president's prize given by the Glasgow Institute of Architects were exhibited. Later on in the evening the ordinary meeting of the association was held—Mr. James B. Stewart, president, in the chair. Mr. Sellars addressed the meeting. He urged continued application to the study of the profession they had chosen, and offered some practical advice as to the best means for realising the objects the association had in view for the benefit of its members. He intimated his intention of giving a prize for the best design for a cottage, with specification, to be competed for by the members of the association. Mr. Sellars concluded as follows:—"All of you must know that the mere regular performance of ordinary office work for a given number of hours per day is not sufficient to make you accomplished architects. You must have that enthusiasm for your art which will keep its pursuit constantly before your mind; you must have that devotion and love for it which will engender an ever-increasing desire for more knowledge of its subtleties—an ever-growing wish to emulate the immortal works of those who have gone before you—or your chances of rising out of the rut in the great race for distinction are but feeble indeed. In our profession a position is not to be made without hard, earnest, enthusiastic work. But while all this is true, I know of no profession in which there is more pleasure to be obtained. To the earnest, painstaking architect, who has thrown his whole mind into his work, who has faithfully studied its every detail, what greater happiness can there be than to see the fruit of his thoughts embodied in enduring stone, destined, it may be, to influence and to give a direction to the taste of a whole community, and to hand his name down with honour to posterity?" Mr. Mossman then addressed the meeting. He referred to the relations of architecture with the sister arts,

remarking that the art of the best periods was always characterised by a strict adherence to architectonic principles. He concluded by offering a prize for designs of a vase with figure subjects. The customary votes of thanks terminated the proceedings.

SOCIETY OF ANTIQUARIES OF SCOTLAND.—At the usual monthly meeting of this Society held this week, a notice of an ancient Scottish lectern, now in the parish church of St. Stephen, St. Alban's, Hertfordshire, was read by Mr. William Galloway, architect, Corr. Mem. S.A. Scot. Apart from any conjectures as to its history, this lectern is of special interest as being the only known example formerly pertaining to Scotland which has escaped the disastrous issues of civil and religious commotions. Its history is very singular. About the year 1750, when a grave was being dug in the chancel of St. Stephen's church, the lectern was found buried in the soil. It is supposed to have been thus concealed at some time during the Civil Wars. It is of cast brass, and of a handsome design, consisting of an eagle with expanded wings supported by a shaft decorated with several groups of mouldings, partly circular and partly hexagonal. The eagle stands upon a globe, and the shaft has been originally supported on three feet, which are now gone. In its present state the lectern is 5 feet 7 inches in total height. It bears the inscription—Georgius Creichtoun, Episcopus Dunkeldensis. He died 24th January, 1543, and previous to his elevation to the see of Dunkeld he had been Abbot of Holyrood. The probability, therefore, is that the lectern had been presented to Holyrood by the Abbot on his elevation to the see of Dunkeld, and that it was taken from Holyrood by Sir Richard Fea of Sopwell, who accompanied the Earl of Hertford in his invasion of Scotland in 1543. On his return Sir Richard presented to the parish church of St. Alban's a brazen font bearing a magniloquent inscription, to the effect that though previously designed for the baptism only of the children of kings, it now, in gratitude for its rescue from the fire which consumed Edinburgh and Leith, performed the same service for the meanest of the English. This font, which was doubtless abstracted from Holyrood, is no longer known to exist, and there seems no reason to doubt that the lectern which was saved by being buried during the Civil Wars, was abstracted at the same time, and given to the parish church of St. Alban's by the donor of the font. Mr. Galloway concluded his paper by urging the Society to take some steps to have this interesting relic restored to Scotland. Drawings of the lectern were exhibited. The next paper, also by Mr. Galloway, was a notice of a sculptured stone in the old churchyard of Tullihole, Kinross-shire.

CHIPS.

New schools have been completed for the Thetford School Board, and are to be opened early in May. Mr. J. B. Pearce, of Norwich, is the architect, and Mr. Bardell is the contractor.

A new Calvinistic Methodist Chapel is about to be built at North Risca, South Wales. Messrs. James and Bevan are the contractors, and the architect is the Rev. A. Davis, of Rhymney.

The organ recently purchased for the Wesleyan Chapel, Lewes, was opened on Sunday week after repairs by Mr. Starnes, of Lewes. The instrument was built by Snetzler in 1751, and is one of the many respecting which the tradition exists that Handel used frequently to play upon it.

Mr. Armstead will contribute to the Royal Academy a recumbent tomb-statue in marble of the late Archdeacon Moore, to be erected in Lichfield Cathedral, near the similar memorial by the same sculptor of Dean Howard.

A cocoa house was opened on Friday in the Market-place, Wednesbury. The alterations were carried out by Mr. George Morris, of School-street, in the same town.

At a ratepayers' meeting at Llandilo-fawr held on Thursday, the 3rd inst., it was decided to take steps for raising and restoring the tower of the parish church, and placing therein a town clock. A committee was appointed to act in the matter.

The failure of Mr. Edwin Clark, civil engineer and contractor, was announced in the London Bankruptcy Court on Monday week. The liabilities are set down at £760,000.

The Brighton School Board have instructed the surveyor to prepare plans for proposed new schools at Preston.

The Masonic Hall, Dorchester, has just been re-decorated, &c., by Mr. Gould, of that town.

Building Intelligence.

BELFAST.—New schools have been erected in North Howard-street, Belfast, by Miss Charters as a memorial of her father. The buildings comprise on the ground floor a boys' and girls' school, infants' school, with classroom, cloak-rooms, &c. On the first floor is placed a hall for instruction in cookery to accommodate 120 persons. The main entrance from North Howard-street is placed under the tower, and has deeply moulded joints, from which springs a Tudor arch with a flat label moulding, on which is placed a datestone with pediment and scroll-work. All the external walling is of Scrabo sandstone, with the dressings of windows and doors neatly tooled. The gables are coped with stone moulded barges, and have kneelers and summits finished with stone terminals. The style adopted is a modification of that prevalent in the seventeenth century. Messrs. H. and J. Martin were the contractors. The buildings have been erected from the plans and under the superintendence of Messrs. Young and Mackenzie, and the total cost is about £2,500.

BERRY POMEROY.—The parish church of St. Mary, Berry Pomeroy, Totnes, South Devon, has undergone thorough restoration. The north transept chapel has been carefully cleaned, as also the Star-tomb, which is supposed to contain the remains of Sir Richard Pomeroy, who rebuilt the church in the latter part of the Fifteenth Century, when the south aisle was added. The chancel has been laid with encaustic tiles, and the new altar, which is of massive carved oak, is reached by three stone steps, along the second of which are placed elaborately-traceried rails, also of oak. A stone sedilia has been placed on the south side. A new oak pulpit, on a plain pedestal of Bath stone, is situated on the north-east side of the nave, and a lectern has been presented. The celebrated carved and illuminated screen has been carefully treated; and the removal of some old pews, and a quantity of dirt and varnish, has revealed a number of panels on which are paintings of saints and the four doctors of the Western Church. This screen has formed the basis upon which the whole of the architectural features of the church have been renovated, and where it had decayed or become mutilated, well-seasoned oak has been re-inserted, and now it stands almost as perfect as when it was first constructed. The nave and aisles have been re-seated. The columns, which were from thirteen to eighteen inches out of perpendicular, have been restored to their original positions, and each one has been thoroughly cleaned, the result being that an inscription was discovered on each of the capitals. Eleven new windows, of five lights each, with tracery, have been inserted, and the east window has been lowered to correspond with that at the western end. The floor is inlaid with Minton's tiles. The cost of the restoration is £3,000, and it has been carried out under the superintendence of Mr. Jeffery Michelmores, architect.

DIXON GREEN.—The new Church of St. Thomas, at Dixon Green, near Farnworth, was consecrated on Easter Monday. The church is in the Early English style, built of Yorkshire stone, and is plain but substantial. Internally it consists of nave and chancel, having a total length of 139 feet, and is capable of accommodating some 630 persons. It has cost about £8,000. Mr. J. S. Rawson, of King-street, Manchester, was the architect.

ECLES.—The new church of St. Andrew, Eccles, was consecrated on Wednesday. The designs were prepared by Mr. H. E. Tijou, of Manchester. The length of the building, which will seat 800 persons, is 126ft. 6in. by 55ft.; the height is 60ft. It is built of Durnford Bridge parpints, with dressings of Storton Park stone. The cost of the building is £8,000, but the tower is incomplete, and it is not intended to proceed with it at present.

HARROGATE.—The new chapel erected by the Wesleyan Methodists at Harrogate was opened last week. The building is in the Early Decorated style. The outer wall stones have been supplied from the Killinghall quarry, and the ashlar dressings from Leeds. The chapel possesses a nave, two transepts, and a chancel. The walls are finished in plaster. The chapel is heated by hot water, and Messrs. T. and R. Boote, of Burslem, supplied the tile work. The

cost of the building is estimated at £10,000, and it will accommodate about 750. It is expected that when the spire is erected it will augment the expenditure to upwards of £11,000. All the work has been carried out under the superintendence of the architect, Mr. George Woodhouse, of Bolton-le-Moors.

MELBOURNE.—The Wilson Hall of the Melbourne University, now in course of construction, is the gift of Sir Samuel Wilson, who is a member of the Upper House of Parliament in Victoria and a wealthy landowner, to the University of Melbourne. It is now about four years ago that, actuated by feelings of liberal gratitude to a colony that had handsomely responded to his own energy, he conceived the idea of presenting the colony with a testimonial of his feelings and worthy of acceptance. The want of an examination-hall at the university was greatly felt, and to remedy this inconvenience Sir Samuel Wilson conceived the idea of presenting a sum of money sufficient to build a hall worthy of the institution, to be used for great academical ceremonies. Messrs. Reed and Barnes, the architects of the university, were instructed to prepare the necessary designs and drawings, and to call for tenders for the work. The lowest tender was £36,707 10s. 6d. from Messrs. Nation and Co., builders, Melbourne, and the work is now in active progress. The style of the building is Gothic of the Perpendicular Period. The walls, which stand on a plinth of blue basaltic stone, are of freestone. The exterior face is of sandstone of a good quality, and the interior of a limestone very similar in quality and colour to the French Caen stone. The roof is an open timber one of elaborate design, resting on stone corbels, and covered with slates. It is surmounted with a ventilating lantern, and furnished with ventilating gables. The hall is divided into bays, a larger one forming the dais; the total internal length is 140ft., and the width 47ft. The height of the walls from the ground is 55ft., and the height of the roof 87ft. The bays are divided externally by buttresses surmounted by pinnacles, and each side bay is lighted by a three-light window. The dais is lighted by two large bay windows, that on the east side being octangular in form, and that looking into the quadrangle rectangular. The main entrance is in the north end, and consists of the three doorways shown in the drawing. They open into an entrance-lobby, which is connected with the present university building by a corridor. There is also a side entrance in the western bay window leading into the quadrangle. Above the entrance-door internally is the large archway of the organ gallery; in connection with this gallery is the block of buildings which is designed to connect the new hall with the present building. It contains the rooms necessary for instruction in music whenever a professor of that art may be appointed. The hall is placed at the south-east angle of the present building, and is to be connected with it by the block of buildings above mentioned, the whole forming an extension of the east side of an open quadrangle.

MELBOURNE.—New offices for the proprietors of *The Age*, *The Leader*, and *The Illustrated Australian News* newspapers have been erected in Collins-street East, Melbourne. The new offices consist of five floors, and were erected from designs prepared by Messrs. Reed and Barnes, architects, of Melbourne, the front elevation being of the Corinthian order. The foundations and basement story are very strongly constructed of bluestone and brickwork, the latter being twenty-seven inches thick. The ground floor, which is approached from the street by a flight of stone steps, is devoted chiefly to the general offices, and the publisher's room; the former being thirty-six feet by twenty-one feet, and the latter thirty by twenty-six. The fittings are of cedar. On the first floor are situated the rooms devoted to the use of the proprietors, editors, and sub-editors. Immediately over the literary department, on the second floor, are the composing and stereotyping rooms. The third floor covers about the front half of the composing-rooms, and is given over to the use of the artists and engravers. The cost of the building and plant was about £20,000.

NEWPORT.—Memorial stones of a new Bible Christian chapel were laid at Newport, Isle of Wight, on April 8. The chapel is being built from the designs of Mr. Frederick Mow, architect, of London. The style of architecture is

Gothic. The roof will be opened-timbered, of handsome design, and the chapel will be terminated with an octagon-shaped organ gallery—behind the rostrum—inclosed by a badly-recessed arch. Behind the chapel, in addition to the schoolroom—53ft. long and 21ft. wide—there will be vestries for the ministers and stewards, and kitchen on the ground floor, and class and retiring rooms on the gallery level. The chapel will afford accommodation for about 600. The builder is Mr. Isaac Barton, of Ryde. The cost will reach £5,000.

QUEENSTOWN DEEP-WATER QUAY.—This work, owing to the energy of the contractor, Mr. John Delany, of Cork, who has lately completed his preliminary arrangements, which were necessarily tedious and expensive, is now progressing in a most satisfactory manner; the large concrete blocks, weighing over 100 tons, are being rapidly made at White Point, at which place they will be lifted by means of a powerful floating shears, conveyed to the site of the quay, and lowered into position at a depth of twenty-six feet below low-water mark. Large quantities of material being ready for use on the spot will insure, during the summer months, rapid progress in the work, the completion of which will be of immense advantage to so important a point as Queenstown.

RADSTOCK.—On Tuesday, the church of St. Nicholas, Radstock, was re-opened, after having been restored and enlarged. Mr. Wilcox, of the firm of Messrs. Wilson, Wilcox, and Wilson, architects, of Bath, prepared designs, and from his drawings the affair has been carried out at an expenditure of about £2,550, by Messrs. Wall and Hook, of Brimscombe. The old chancel was taken down and the whole east end of the building cleared away. The church was then extended about 30ft. eastward, and an entirely new chancel constructed. The galleries, which were very unsightly, were removed, new roofs formed, and an organ chamber and vestry built. The style adopted in the original church—Early Decorated—has been adhered to, and such portions of the structure as could be utilised were allowed to stand, so that a portion of the south wall, the porch, and west end remain. The tower was untouched, except that the internal arch is restored. The new structure will seat 113 additional worshippers, besides those who could have been accommodated in the galleries, and altogether there is room for 520 persons in the church.

ST. BARTHOLOMEW'S HOSPITAL.—An addition to St. Bartholomew's Hospital is in course of construction, consisting of a library, practical classroom, museum, lift-rooms, and offices. The frontage to Giltspur-street displays a Classic elevation. The base is composed of Dalbeattie granite, and is 7 feet 6 inches in height. The upper portions consist of Portland stone, with intermediate Aberdeen polished granite panels sunk and moulded. The principal room in the interior is the Turnerian museum, 26 feet 6 inches by 96 feet 6 inches. The height is 26 feet from the floor to plate of roof, and 15 feet from plate of the roof to ceiling. The lighting is effected by a skylight and lantern-light. The staircase to the offices is of Dalbeattie granite. The grand staircase, as well as all the internal stairs, are composed of choice Craigleith stone. The material used in the construction of the offices and lift-rooms is white glazed brick facings, supplied by the Farnley Iron Company, near Leeds. The building has an iron span roof by Messrs. Moreland and Son, who also furnish the girders. The architect is Mr. Edward T'Anson, Laurence Pountney-hill; the contractor, Mr. Deputy Brass, Old-street; the clerk of works, Mr. G. Streeter; and the builders' foreman, Mr. A. J. Pearce.

ST. GILES'S CATHEDRAL, EDINBURGH.—The work of restoring the southern section of St. Giles's Cathedral, Edinburgh, has been in progress during the past two months. The first thing done in the way of restoration was to clear out the Chapman aisle, which is immediately east of the south transept. The restoration committee were surprised by not finding in that aisle the remains of the Marquis of Montrose, which, according to tradition, were interred there in 1661. It was conjectured that they would be found in one of the vaults. As it would be satisfactory to have this point as well as some other points cleared up, an exploration of the vaults was made on Thursday week, and Dr. William Chambers, chairman of the restora-

tion committee, has reported. No discovery was made of the coffins of the Earl of Murray, the Earl of Athole, the Earl of Montrose, or the Marquis of Montrose. Some further examinations will be made, but it is not likely that there will be any fresh discovery. In short, it would appear as if the bones of the great marquis had vanished. It is expected that the restoration of the southern section of the building will be completed in the summer of 1880. The expense is estimated at £1,500.

SNAILWELL.—The parish church of Snailwell, which from dirt, decay and neglect had become utterly unfit for use, was reopened on Easter Sunday after restoration from the designs of Mr. R. Reynolds Rowe, F.S.A., of Cambridge. The roofs have been re-slatted, the walls and masonry cleansed and repaired, and the south aisle and porch have been rebuilt. The chancel, which was whitewashed outside and propped up by miserable brick supports, has now an exterior of flints and wrought stone; the fittings have been replaced by others more in character with the church, and all the windows have been filled with stained glass. The steps are of rubbed Mansfield stone, and the floors of rich tiles, and the patron has presented a reredos of stone and alabaster. The church is seated with oak throughout. A stone pulpit has been built close to the north-west side of chancel arch. Of the new stained-glass windows, one is by Mr. Constable, of Cambridge, and the other ten are by Messrs. Cameron, of Duke-street, Manchester.

STOURBRIDGE.—The new cemetery at Stourbridge was consecrated on Monday week. The Board have borrowed £7,500 to meet the cost of the cemetery, of which the ground cost £1,123, and the tenants' interest in it £120. The contract for the two chapels and lodge amounted to £2,500. The cemetery consists of eleven acres or thereabouts, a little over four acres and three roods having been allotted for consecration. The grounds have been laid out and the buildings designed by Mr. Smalman Smith, architect to the Board, the previous designs sent in competition having been set aside. The chapels are cruciform in plan, the consecrated portion being on the east and the unconsecrated portion on the west, of a central tower with entrance and exit portals. There are two vestries and a crypt. The spire is 100ft. in height, and is covered with English oak cleft shingles. A portion of the interior is lined with brown and white stone. The chapels, lodge, and inclosure walls have been built with brown stone, the gift of Mr. J. Amplett, of Clent, and 6,452 tons of this material have been used. Bath and Grinsell white stone are used for the dressings and weatherings. The style of decoration is that of the Geometric period. Mr. S. Guest is the contractor for the chapels and lodge.

WISBECH.—The new schools for girls and infants at Elm-road, Wisbech, have been opened this week. The elevations as seen from the Elm-road are of the Early Pointed period, and built of white bricks and stone. The north-west elevation has a bell tower terminating with a spire carried by shafts of Mansfield stone with foliated capitals. The school for girls is 5ft. long and 20ft. wide, and two class rooms each 20ft. and 18ft. wide, capable of accommodating 200 girls. The school for infants is 39ft. long and 20ft. wide, with gallery and a class-room 20ft. and 18ft. wide, capable of accommodating 150 infants. The entrance to the schools is 20ft. by 18ft., to be used for a cloak room. The work has been carried out by Mr. Henry Farrow, builder, from plans and under the directions of Messrs. Adams and Son, architects, Wisbech and Lynn.

The Shropshire magistrates received at the quarter sessions last week a report from Messrs. Martin and Chamberlain, architects, of Birmingham, with reference to providing additional lunatic accommodation. The report was in favour of enlarging the present joint asylum at Bieton by 200 beds, of which it is quite capable, in preference to building another elsewhere. The consideration of the question has been adjourned till July.

The *Isle of Man Times* complains of the slow progress of the Battery works at Douglas. The work is being carried on for the House of Keys under the superintendence of Mr. Powell, who receives, so this journal states, a salary of £1,200 per year while the work proceeds. The battery was expected to have been completed at the close of 1878.

More than Fifty Thousand Replies and Letters on subjects of Universal Interest have appeared during the last ten years in the ENGLISH MECHANIC AND WORLD OF SCIENCE, most of them from the pens of the leading Scientific and Technical Authorities of the day. Thousands of original articles and scientific papers, and countless receipts and wrinkles embracing almost every subject on which it is possible to desire information have also appeared during the same period. The earliest and most accurate information respecting all new scientific discoveries and mechanical inventions is to be found in its pages, and its large circulation renders it the best medium for all advertisers who wish their announcements to be brought under the notice of manufacturers, mechanics, scientific workers, and amateurs. Price Twopence, of all booksellers and news-vendors. Post free 2½d. Office: 31, Tavistock street, Covent-garden W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 33s. 30c.). To India (via Southampton), £1 6s. 6d. To any of the Australian Colonies New Zealand, the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

N.B.—American and Belgian subscribers are requested to remit their subscriptions by International P.O.O., and to advise the publisher of the date and amount of their remittance. If the last-mentioned precaution is omitted some difficulty is very likely to arise in obtaining the amount. Back numbers can only be sent at the rate of 7d. each, the postage charged being 3d. per copy. All foreign subscriptions, unaccompanied by an additional remittance to cover the extra cost of forwarding back numbers, are commenced from the next number published after the receipt of the subscription.

Cases for binding the half-yearly volumes, 2s. each.

RECEIVED.—J. L. A.—J. B. and Son.—S. L. B.—B. of T. W. G. H.—J. A. and Son.—C. Bros.—J. T. W. Z. (Yes; full reports have appeared in recent numbers of the ENGLISH MECHANIC).—BROSELEY. (Stanford's patent joint is manufactured by Messrs. Doulton and Co., of Lambeth).

"BUILDING NEWS" DESIGNING CLUB.

DRAWINGS RECEIVED.—Nemo.—J. J. C.

CORVUS (the scale for village school chapel is of course intended to be 1/4in. scale).

The following drawings came too late for review:—Omega, Triangle in Circle, Try Again, Be Mindful, and Amphion. We shall refer to these designs next week.

Correspondence.

THE SOCIETY FOR THE PROTECTION OF ANCIENT BUILDINGS.

To the Editor of the BUILDING NEWS.

SIR,—As there seems to be an impression growing up in the mind of the public that the above society is actuated by feelings of disregard for the structural preservation of ancient buildings, and as such an impression is likely to seriously interfere with the important objects which they have in view, I have been requested by the committee of the society to ask you to insert their most emphatic denial of any such sentiment on their part. The urging on the public of the necessity of doing structural repairs to ancient buildings in time to prevent decay and keep out wind and weather is one of the primary objects of the society, and they have on several occasions had to deplore in the cases of ancient buildings brought under their notice that money which ought to have been expended on the structural repairs have been worse than wasted in utterly destroying the beauty and historical value of the interiors.—I am, &c., WILLIAM MORRIS, Hon. Sec. 9, Buckingham-street, Strand, W.C., April 8th, 1879.

A UNIVERSAL DICTIONARY FOR ARCHITECTS.

SIR,—In the notice which appeared in your issue of April 4 of a Universal Dictionary for Architects, &c., of which I am the author, you state that "the

assumption in the preface that 'excepting the Dictionary of Architecture there is no book which exclusively contains in alphabetical order a fair approach to a complete repertory of architectural and building artificers' phraseology' is inaccurate." I say in my preface that "excepting the Dictionary of Architecture there is no book which exclusively contains in alphabetical order a fair approach to a complete repertory of architectural and building artificers' phraseology and terms." Now, I maintain that, with the exception named, there is no such book—of course I mean published in the United Kingdom—and from the nature of my investigations, for some time past, I consider that I am fully competent to decide on the point.—I am, &c., April 8th. WYVILL JAMES CHRISTY.

Intercommunication.

QUESTIONS.

[5733].—**A Six-roomed Two-Story House.**—I shall feel very grateful to any reader of your journal who will inform me where I can get a book or in what number of BUILDING NEWS I may be able to glean some information in wooden structures, also difference in cost of wood and concrete building? Also the kind of wood best adapted to stand exposure in the outer wall, and if there is not a better and more durable way of building with wood than frame partitions and weather boarding? I purposed making the outer wall of solid 9 x 3 deals, covering the inside with hair felt, and fixing 1in. wrot deal lining as a finish in lieu of plaster, making all main angles, window and door frames and plates 6in. x 6in.—**A POOR COTTAGE, Far West.**

[5734].—**Resin-and-Beeswax Jointing for Brickwork.**—In a biographical notice of Earl Beaconsfield in *Mayfair*, entitled "The Biggest Ben," occurs the following:—"One very curious circumstance should not be forgotten. The house referred to above as that in which Benjamin Disraeli the first 'ate macaroni dressed by the Venetian Consul' was in existence until within a very recent period. It was one of the finest specimens of Jacobean architecture extant. The bricks were of the best quality; they were ground down to a true surface, and instead of being cemented with mortar in the usual way were brought together with a mixture of resin and beeswax. In the terra-cotta thus formed, carvings of no small beauty were executed." Can any of your readers supply any more detailed account of the process, and state whether it is one which is suitable for present workmanship?—Q.

[5735].—**Australia.**—Could any of your readers kindly give any information about architects' assistants in Melbourne or Sydney? What chances they have and what salary they get. Any information will be thankfully received.—S. B.

[5736].—**Softening Plaster of Paris.**—I have a delicate marble structure to remove and re-erect. Will some experienced reader kindly say the best way of softening the plaster, separating the pieces and cleaning down when finished?—A CONSTANT READER.

[5737].—**Load on Beam.**—Would one of your numerous readers give me a simple rule to find the following:—A beam supported at both ends and loaded at a single point; determine the proportion of the load borne at A and B respectively? Also how the constant for fir is

found or derived?—CAVENDO TUTUS.

[5738].—**Attics.**—Will someone kindly recommend from experience a good non-conducting substance with which to line the inside of an attic roof exposed to the sun? The attic is open to the slates, and well ventilated.—W. B. D.

[5739].—**Sewage Way Leave.**—The question of price to be paid for increased size of main sewers having been agreed, the one of way leave now is a debatable point, and a very important one, too, so much so as to nearly upset all past arrangements. Any information from your readers would greatly oblige as to what has been paid for way leave per mile, or how?—R.

[5740].—**English, French, and German Architectural Dictionary.**—Can any reader inform the inquirer whether there is a "Dictionary of Terms in Architecture and Building Construction" translated from English into French and German.—CORVUS.

[5741].—**Shop-Front Work.**—Will some fellow-reader give me the benefit of their experience in shop-front work—viz., is it advisable, when erecting shop-fronts, with brick building over, to build on the front girder (a fifth one) until it begins to deflect, before putting the iron columns under it, or is it best to fix the column before building on girder at all?—CONSTANT READER.

[5742].—**Drainage.**—Will some reader of your paper inform me what the law is with reference to owners of houses draining into sewers put in the public roads and streets by the local authorities where the local rates are already levied? Whether the local authorities are compelled to bring the drain to a person's premises, or whether the owners have to pay for the drain outside their premises so as to connect it with the sewer, no matter what distance or depth in the public road or street it may be laid.—A. C.

[5743].—**Responsibility for Quantities.**—I shall be glad if some of your (quantity surveyors) readers would kindly give me their opinions of the following queries: Has an architect a legal right to make arrangements with the quantity surveyor whereby he receives for himself half the commission without his having done any portion of the work in preparing the quantities? Can he do so and retain a honest position with his client? Assuming the quantities turn out deficient, does he not compromise his position as independent arbitrator in giving his final certificate under the usual clause in contract that it shall be binding on both parties? When the commission is so divided, who is responsible for deficiency of the quantities?—C. A. H.

[5744].—**Removing Grease from Photographs.** Can any reader recommend a sure method of removing lamp-oil marks from photographs without damaging the same? Hot iron and benzine have been tried without success.—M. E. S.

REPLIES.

[5699].—**Driving Sewer Headings.**—To get the dirt out of heading in long distances requires more headroom than short distances. Have a small trolley long enough to hold two skips, one to be landed on trolley whilst the other is sent up shaft—say, in a temporary road with temporary rails or some quartering, with hoop iron on top to prevent the wheels of the trolley from wearing the timber. In filling heading there is no difficulty. Put dirt back in heading and pun it. There is no trouble in getting timber out in moderately good ground. Remove some of the side piling boards first, then the props, then fill up as closely as possible to head tree before removing it.—JOHN T. WELCH, Contractor, Tiverton-on-Avon, Bath.

[5709].—**Perspective.**—In determining the arrangement of lines for an interior perspective, it would be unwise to trammel oneself at the commencement by an endeavour to adhere to a fixed or predetermined number of degrees to be exactly contained in what might not be inaptly called the angle of observation. What is necessary to observe is that such does not exceed 60°, such to include the whole of the picture plane, so far as the horizontal angle is concerned. The degrees in the vertical angle of observation are not usually considered, nor can it be necessary to do so as we are not compelled to cast our eye to the nearest point in the ridge, but the picture requires the roof completed as a rule. In the diagram sent, suppose Fig. 2 2 2 2 to be a church plan taken clear of openings for the purpose of simplicity in illustrating. Let

some special purpose, and to be seen from the distance K P, then A B would be the picture plane, and the lines A P and B P would contain the angle of horizontal observation, being much less than 60°, and K 1 will be the projection of the centre of the east end. Case 2. We could make C D the picture plane still containing less than 60°, and where K 2 will be the projection of K. Likewise may E P, G H, and I J each be made a picture plane, when in the latter K 5 will be the projection of K, and L will in any picture plane nearer the spectator have its projection in the radial line I P. Likewise M in M P, N in N P, and O in O P. Now if angle I P J be measured with a protractor it will be found to contain—say, 60°, and therefore we cannot adopt a picture plane nearer to the point of sight. Then, supposing that we have drawn a perspective on picture plane I J, we could, with a pair of compasses, clip it round its edges so as to become identically the same as the perspective on line G H, and repeat the operation successively for any imaginary number of picture planes drawn parallel to and within I J, and when we should have a complete perspective left, whence it is manifest that a perspective may be drawn with a pyramid of rays, having for its oblique base the section of the interior of the church depicted, and its side which lies on plan not exceeding 60°, but may be less. Finally, with respect to the necessity for the picture plane to be parallel with the east end wall—i.e., at right angles with the axial plane. In our method we have assumed it is always to be so, but many artists don't draw it parallel, and then per necessity all their transversal lines must tend to a vanishing point, not being the point of sight, but in parallel perspective. There is but one vanishing point which is the point of sight, and they are then therefore drawing in oblique perspective and correct in every particular; but by some persons conventional parallel perspective—i.e., with the point of sight without the axial plane—is preferred, although such really is slightly oblique perspective, ignoring one vanishing point and calling the other one the point of sight. True parallel perspective would give an artistic picture with little else but monotony, and at variance with perhaps the first fundamental axiom of all artists—viz., that the point of sight should be to the right or left of the centre of the intended picture. Oblique perspective for an interior will at once prohibit any transversal arcs from being drawn with the compasses. All such would then become elliptical curves in perspective, and would require very much extra time to project them correctly, and then they would not look so well as geometrical arcs drawn from centres. Hence, perhaps, is the principal reason why conventional parallel perspective is preferred—i.e., to save work and gain effect though nothing can equal a good photograph which, if not taken in the centre, must be in oblique perspective, and in such every curve must be correctly projected; and it would be an instructive exercise for anyone having the time to spare to draw a perspective of an interior of a large church on the oblique system to a large scale, and get some church photographed from exactly the same point of sight, height also to an inch, and then get the drawn perspective reduced to exactly the size of the photo by photolithography, and then carefully trace same and make another tracing of the leading lines of photograph and then place one tracing over the other and see the difference. Also might the large drawn perspective be shaded according to the intelligence of the artist, especially with respect to how the light will fall on circular and octagonal Gothic capitals and reduced to the size of photograph and compared, and some startling discoveries might then be made.—HENRY AMBROSE.

[5725].—**Substitute for Mortar.**—If "A. S." desires a stuccoed surface, Portland cement and good clean sharp sand, free from saline impurities, in the proportion of 1 to 2 is the best substitute to use. Francis's cement is reliable. Lime and river sand are the worst possible kind of protection in an exposed or damp situation.—G. H.

[5726].—**Breaking Weight of Girders.**—In the first case mentioned by S. W. Leeds, the useful formula for flanged joists may be taken, or, $W = 7 \frac{ad}{L}$ in which

a = area of bottom flange up to the top of rounded angles, d = depth in inches, L length in feet, and W = breaking weight in tons. In this case the extra plate produces no additional strength worth notice, as the lower flange takes the principal strain. 2. When a plate is added to the top and bottom, I should simply take the additional sectional area of the plate added to lower the flange. In the case of 3, I am not aware of any experiments upon which a reliable formula can be based. The only rational method of considering two such girders united by top and bottom plates is to use the same formula, adopting a slightly lower multiplicity, treating the girder as a box girder. The tables, published by Measures Bros., Rowson, Drew, and Co., Henderson, and other rolled girder establishments, may be obtained for such combinations, and are, as a rule, reliable.—G. H. G.

[5726].—**Breaking Weight of Girders.**—In reply to T. W. Leeds, the best formulae for rolled joists having a plate on the top would be those derived by the average strength of numerous examples from different makers, and not made with a view to their being tested. Perhaps such has not as yet been accomplished, and if not we may arrive at some conclusions more or less trustworthy by considering the known strength of the material and the mechanical nature of the strains to which in such cases it will be subjected. Let us suppose that wrought iron girders could be made in one piece and without rivets, then let us consider the actual strength of the material when subjected to a direct strain, neither multiplied nor diminished by mechanical agency. First let us take tensile strength. It is generally conceded that sound wrought iron of a good quality may safely be subjected to a strain of 5 tons per inch. With respect to the compression of wrought iron its strength is slightly dependent on its being kept straight if in any length, and when under those conditions its known strength or we might, perhaps, with more truth say its unknown strength, is considered to vary according to the quality of the iron, there being several kinds of malleable iron, some of them of near affinity in nature to the soft grey cast iron, and being fit to sustain a safe compression of from 2½ to 4 tons per square inch. It will therefore be likely that the top flange should be greater in sectional area than the bottom flange, and it is usually made about the same, but the rivet holes weaken the bottom flange by—say, 1-3rd, and thus top flange becomes to bottom flange as 3 to 2, and if the top flange

material were of 4-5ths the strength for strain resistance then the ratio of 5 to 4 in areas would give the required strength, but we have the greater ratio of 3 to 2, which we assume to be sufficient. We have, of course, always the difference between a crushing and a safe strain already provided, and which would cover any unexpected deficiency in compressible power of resistance, should such exist. The preceding is based on the assumption that the neutral axis must, per necessity, exist in the centre of the depth, but such may not, may, probably is not, really the case, but, however, let us proceed to consider the rolled joists with plate on the top. A rolled joist has its top flange of the same sectional area as the bottom flange, and therefore as it is of malleable iron it requires the top flange to be greater by at least 1-5th than the bottom flange, and if the metal were only capable of offering a safe compressible resistance of 2½ tons per square inch then it would require to be twice the area of the bottom flange in order that the neutral axis may be kept in the centre, because if the top flange be weaker than the bottom flange it is then evident that the fibres in top and bottom flanges would have to break simultaneously, and that therefore the neutral axis would exist at such place as would give equal power to each flange, and the top one would then be deeper and their proportion could approximately be determined provided we knew the relative tensile and compressible powers per square inch of the iron and the exact thickness of flanges and breadth and thickness and depth of web; but to keep the neutral axis near the centre we shall equalise the strengths of the flanges, and find it very convenient to put a plate on the top, and if such exceeds the proportion of 2 to 1 with respect to the bottom flange, then we have a little excess in strength, or we may consider neutral axis now to be nearer the top. That our theory is correct will be evident from the consideration that if the top flange were to become—say, a foot thick, and the web and bottom flange together an inch, then the neutral axis would necessarily exist in the top flange itself, which would practically in theory become a solid girder. Hence it follows that we may consider a rolled joist with a plate on the top if riveted to same to be

calculated by Fairbairn's formula $W = \frac{cad}{L}$ where W = breaking weight in tons, c is the constant—say, perhaps 65 for a rolled joist and plate on top, but the constant would vary with the proportion of the flanges, also the web, and might be as much as 75 for a broad strong joist of thick metal, and 80 for two or three stout rolled joists with plates top and bottom; a is the area of bottom flange in inches, and from which deduct what rivet holes there are in cross section; d is the depth taken, I should say, from near centre to centre of flanges, which gives the average of their working power, and being in inches, L is the length in inches. Now, where there is a bottom plate find the area of the top plate, and do not, until a better method be found, allow more than about ½ or, say, 2-3rds at the utmost of the area of the top flange to be taken for use in the formula as the area of the bottom flange, and then we should be safe from wasting knowingly any metal or being likely to run short in strength, but the bottom flange must equal the area used. The strength of iron being uncertain, we shall be right in making an allowance for contingencies. There being two, three, four, or any number of rolled joists side by side with a plate on top and bottom, will make no difference to the application of the formula. The calculation of the equalisation of strength of top and bottom flanges would in method vary according to the conditions given when the neutral axis would not be in the centre, but such girders are not fully utilising the metal-saving principle of making the flanges sustain the strains to the best advantage, because taking an extreme case and supposing we had no top or bottom flange, then we must increase the web much to prevent its twisting, when it will at once be apparent that the extra metal in the web could have been disposed to greater advantage in the flange of which we are inquis, but if such were necessary from any cause they could be calculated by integral increments having their origin in the neutral axis. Supposing a girder already made and having its neutral axis evidently not in the centre and knowing the strength of the metal, in order to find its neutral axis we should directly discover that the power in either flange was a function consequent on its unknown distance from the sought neutral axis, but by working on the integral system from an assumed neutral axis, and using a similar web and flanges, we can, after a few efforts, discover a near approximation to what we seek.—HENRY AMBROSE.

[5728].—**Coloured Building Stone.**—I am not acquainted with the stone called "Findon" stone. I should think "W. W." means "Finglas" stone, quarried near Dublin, the colour of which is grey or blackish in tint. It is a limestone, and largely used. I will mention a few stones of a yellow or red colour:—Ancaster, an oolite, cream-coloured, works easily, used in the St. Pancras station; Barnack Mill, Stamford, light brown, shelly, used largely in the Lincolnshire churches, and in N. Suffolk; Casterton, Stamford, light brown in colour, used in Ely Cathedral; Douling, a light brown, a good, easily-worked, and even-grained stone; Combe Down, cream colour, well known as a good material; Haydon stone, of a brownish colour, used about Grantham; Painswick, a cream-tinted stone, used in Houses of Parliament; Puddicote, brownish, used in Oxford; Yeovil, brownish yellow; Ketton stone, cream and pink, a durable stone; Anston stone, a cream brown; Mansfield stone, yellow, and Bolsover Moor, both well known for decorative purposes. All these are limestones. Of sandstones, I may mention Bramley Fall, a brown stone, very durable; Mansfield stone, a siliceous dolomite, of which there are several varieties. The red variety is well known, and makes a very excellent contrast with the greyer varieties. The dark coloured stones are the best. It may be seen used at the St. Pancras Hotel. Bedston, Carlisle, Corsehill, Fulford, Grimshill, Northfield, Parkfield, Kenton, Scotgate Ash, Shipley, Mallow, Money Point, Clure, Tyn-y-Cwm, and Spinkwell, are names of other quarries where brown or yellow-tinted sandstones are met with. I cannot speak here of the cost of transport, but many of them could be supplied at moderate cost.—G. H. G.

[5729].—**Pointing Red Brickwork.**—The material I have found to stand the best for pointing brickwork is mortar made of lime, procured from Barrow, in Leicestershire, mixed with fine sharp sand. It should be made up at least one month before it is used, and instead of adding water to soften it it should be beaten with a stout wooden

K L be the axial plane, and P the point of sight, and K P the central plane. Let lines A B, C D, E F, G H, and I J contain the plans of points in walls and in ridge, which may be shown in perspective. Case 1. Now if (as might be the case) one wished to depict the east end alone for

staff. By this means I have worked the mortar into a proper degree of plianeness after it has lain three months on the brick floor of a shed. Twenty-three years ago I used such a composition for pointing a building in a very exposed situation, and there are no signs whatever yet of any decay in the joints. Just before the pointing is done the brickwork should be saturated with water. The joints should be formed with a jointer of about 3-16in. gauge. In good brickwork, however, tuck pointing should never be resorted to, but the joints should be struck as the bricks are laid. The question of colour is, of course, governed by taste, but if left to my decision I should certainly not select either white or black, for the reason that either immoderately influences the general tone of the brickwork. If a white pointed building be viewed from a spot sufficiently distant to render the joints indistinct, the difference the white joints make in the colour of the general surface may readily be perceived. The gloomy effect of black mortar may be observed under similar circumstances. I think the pointing material for red brickwork should be slightly lighter in colour than the bricks. For the purpose of colouring the mortar I have in general used dust produced by the cutting of red rubbing bricks, together with a little Spanish brown and Indian red, in relative quantities according to the colour I wished to produce.—J. SAVILLE.

STAINED GLASS.

KING'S LANOLEY.—An heraldic stained-glass window, designed by Mr. J. Clarke, F.S.A., and executed by Messrs. Clayton and Bell, has just been placed in the Edmund de Langley Chapel, attached to All Saints' Church, King's Langley. It is the gift of the Queen, in memory of Edmund de Langley, the fifth son of Edward III., and first Duke of York, whose remains lie by the side of those of his wife, Isabel de Castile, under an altar tomb within the chapel.

DUBLIN.—A stained-glass window, erected as a memorial of Balfe, was unveiled in St. Patrick's Cathedral, Dublin, on Saturday afternoon. It represents Erin, with a pensive expression of countenance, lamenting over her son, and placing on the brow of the medallion a wreath of laurel. The other hand of Erin rests on an Irish harp—an accurate copy of that of Brian Borohme, which is preserved in Trinity College. The inscription states that Michael William Balfe—the most celebrated, genial, and beloved of Irish musicians—was born in Dublin in 1808, and that he died in Rowney Abbey in 1870. The artist of the window is Mr. Ballantine, of Edinburgh.

STATUES, MEMORIALS, &c.

MONUMENT TO GEORGE BUCHANAN.—There is shortly to be placed in Greyfriars' churchyard, Edinburgh, a monument commemorative of the late George Buchanan. The late Mr. David Laing determined to carry out, at his own expense, an idea which he had probably been the first to suggest. The eminent antiquary's notion as to the shape the monument should take embraced, as the leading and essential figure, a bronze head of Buchanan, to be copied from the best extant authority in regard to his personal appearance. A design was accordingly prepared by Mr. D. W. Stevenson, A.R.S.A., which, having been approved by Mr. W. Fettes Douglas, R.S.A., who acted as Mr. Laing's artistic adviser in the matter, was put in train for execution. The stonework has just been completed by Mr. James Kerr, Haymarket, and the bronze casting, modelled by Mr. Stevenson, being also ready, nothing remains but definitively to fix upon the site in order that the erection of the monument may be proceeded with. Mr. Stevenson has shaped his design for a structure 10ft. high. The style adopted is Classic. The ground-plan is square, and the basement consists of several courses of masonry, topped by a cornice and cope. On this rests a square block of stone, having in one of its four sides, each of which measures 2ft. across, an oval niche inclosing the bronze casting. In modelling this head, which stands out in high relief against the hollow background, Mr. Stevenson has followed what was considered as the most authentic portrait in existence. The monument is finished atop with triangular pediments, one surmounting each of the four sides.

WATER SUPPLY AND SANITARY MATTERS.

LANGWATHBY.—The Penrith Union Rural Sanitary Authority have just completed works of water supply for the village of Langwathby. The supply is from a spring at Moor Breast, a mile and a quarter from the village. The number of inhabitants supplied is about 300, and the total length of mains is 3,500 yards. There is a small reservoir at the head, and in the mains are sluice, air, and wash-out valves. Messrs. Watson, Ginn, and Co., of Glasgow, were contractors for the supply of cast-iron pipes; Messrs. Hamilton, Woods, and Co., of Salford, for the valves and hydrants; and Mr. J. Jackson, of Penrith, plumber, for the execution of the works. Mr. Watson, of Penrith, engineer to the Sanitary Authority, designed and superintended the works. The total cost was £568.

RETFORD.—A short time ago some gentlemen were boring for coal in a field near Retford, when they discovered a valuable spring of water. They relinquished the coal scheme and floated a company to supply Retford with water, Mr. C. Tomlinson, of Rotherham, being the engineer. The Retford Council refused to let the company break up the streets of the town, so the latter persons introduced a Bill into Parliament. The Council thereupon started a counter scheme, purchased land to the south-east of the town and commenced boring under the direction of Mr. Fairbank, engineer, London. They have now reached a depth of 170ft., and hope to meet with a supply of water. The question of who shall supply the town with water will be fought out in Parliament.

LEGAL INTELLIGENCE.

AN EMPLOYER FOUND LIABLE FOR INJURIES TO A WORKMAN.—At Bolton County Court, on the 2nd inst., before Mr. Crompton Hutton, judge, a man named Alfred Leather sued his employer, Mr. Thomas Peat, iron-founder, Farnworth, for £50, as compensation for injuries alleged to have been sustained through the defendant's negligence. On May 24th last, the plaintiff, who was foreman over the moulders, was sent for by Mr. Peat to assist in placing an iron beam in position. A temporary scaffolding was put up between the mechanics' shop and a shed by a millwright named Hardy, under the superintendence of the defendant. It was supported simply by four wooden crates, and when the plaintiff and other men got upon it the scaffolding gave way, and the beam fell on plaintiff's thigh, breaking it in two places. Plaintiff was laid up for a long time, and for a certain period was allowed by defendant 10s. per week, but when it was proposed to reduce the allowance he brought the present action. Defendant's solicitor admitted that the scaffold was insecure and ought never to have been used. The judge gave judgment for the full amount claimed, with costs.

CHIPS.

The Society House, Dunganmon, the only building in that town in which public meetings can be held, was re-opened on Monday week, after alteration and renovation.

It is stated that the Duke of Norfolk has subscribed £20,000 towards the erection of the new Oratory at Brompton, to be built from Mr. Herbert Gribble's designs.

The annual exhibition of works executed by the students of the Portsmouth and Gosport was held on Monday week.

Sir Anthony Panizzi, K.C.B., for many years principal librarian at the British Museum, died on Tuesday week, at the age of 82.

The Oswestry town council accepted on Monday week the resignation of Mr. E. B. Smith, and resolved to offer his successor £150 a year.

The concrete foundations are being laid at the intersection of Sackville and Abbey-streets, Dublin, upon which will be erected the statue of the late Sir John Gray. Mr. Farrell is the sculptor, and the preliminary work is being carried out by Mr. Toole, builder, of Dorset-street, Dublin.

A bill is printed, bearing the name of the Lord Chancellor, declaring that the New Law Courts shall be styled the "Royal Courts of Justice."

The Theford Town Council have elected Mr. Burke, of Manchester, as borough surveyor.

A stained glass window has been placed in the chancel of Orton parish church, Westmoreland, by Messrs. Clayton and Bell, of London. The subject is the Ascension of Our Lord.

Mr. Edward Freeman has been elected to the Keepership of the Incorporated Society of British Artists.

The dissolution of partnership of Messrs. Driver and Rew, architects, of Westminster, is announced, and also that of Messrs. A. P. Bell and G. F. Roper, architects, of Manchester and London.

The tender of Messrs. Foot and Lethbridge, for building the Oxford-street Schools, for the Plymouth School Board, at the sum of £3,912, has been accepted. Mr. S. Trevail, of Tywardreath, Cornwall, is the architect.

An apse and vestry are about to be added to the modern Church of St. John, Bury St. Edmunds, from Mr. Wyatt's designs, and it is proposed to place in the same church a new east window, at an estimated cost of about £200. A credence table and fold-stool have just been placed in the church; they were carved by Mr. Tooley from the designs of Mr. Wyatt.

The Torquay Local Board have invited Mr. Ernest Turner, of London, to visit the town and advise upon the best scheme for a fever hospital.

Our Office Table.

From a report just issued by the Derbyshire Archaeological Society, we learn that some further progress has been made during the past few months in the opening out of the ruins of Dale Abbey. The clearing of the Chapter-house has been completed, revealing its fine proportions; and the slype to the south has been further excavated, resulting in the discovery of a doorway into the atrium. A halfpenny of George II., dated 1747, was found on the floor, showing that the complete demolition of the abbey buildings is of comparatively recent date. Beneath the dormitory staircase, in the south transept, the saddlestone of the gable, with the socket for the cross, has been found. The precautions taken to protect the many monuments and other stonework from frost were effectual, no injury having been sustained. The excavations are open to the public daily except on Sundays, on payment of a small charge; the nearest station is at West Hallam, two miles distant. The works at the abbey have been suspended for want of money. The same society is taking steps to preserve and restore to its proper position an almost unique wooden effigy of a canon of All Saints', Derby, with its accompanying cadaver, which are at present rotting away in the town vault beneath the church. The tomb which once supported the figure is doubtless familiar to visitors to All Saints', Derby, as the carved arch with a curious row of figures of monks; it forms the front of what is now the archdeacon's seat. As there are probably not twenty wooden effigies in England, the county Archaeological Society urges the desirability of rescuing this interesting memorial from its present ignoble position.

DURING the laying-out of the new garden on the north-east side of St. Paul's Cathedral, Mr. F. C. Penrose, the cathedral surveyor, directed the workmen to search carefully on the presumed site of Paul's Cross, and at a depth of 6ft. below the surface the foundations were struck upon. They are octagonal in form, and in this respect, as well as in size and character, correspond with the old drawings and descriptions. In his lecture before the Royal Institute of British Architects, in January, Mr. Penrose indicated on a large scale map the most probable site of the Cross, and suggested the possibility of some fragments still existing beneath the surface, and it must be gratifying to Mr. Penrose to find that his theories have proved correct, as in the case of the old cloisters on the south, disinterred last summer. The Cross was erected at some period prior to 1287, when it is first mentioned in a writ quo warranto, and was raised to the ground by order of the Long Parliament in 1643.

MR. GEORGE EDMUND STREET, R.A., is to preside at the annual conversazione of the Sheffield School of Art on the 23rd inst., and will distribute the prizes. The Sheffield school has always stood high amongst the schools of art in Great Britain, and none have beaten it as regards the ultimate success of old students, of whom numbers have gone forth and made a name for themselves. The late Alfred Stephens, the sculptor of the Wellington memorial at St. Paul's Cathedral, was closely associated with it from its earliest commencement; and the late Godfrey Skyes was successively a pupil and second master thereat, remaining there until his appointment at South Kensington. The successors of this lamented and talented artist at the museum, Messrs. Reuben Townroe and James Gambles, are Sheffield School of Art men; so, too, are Messrs. Innocent and Brown, the well-known architects, whose score and more of superb School Board schools form by far the finest and most pleasing architectural feature in smoky Sheffield. Hugh Stannus, the decorator, and Harry Hems, the carver, are both old pupils. George Theaker, head master of the Wedgwood Institute, Burslem, Pigott the painter, Glassby the sculptor, and scores of others known favourably in the art world hail from the same veteran school. An exhibition of the works of past as well as present students will take place at the conversazione.

A CORRESPONDENT asks in the *Times* if it not be to the purpose to promote some inquiry as to the reasons which have produced the change from water-colour painting to tempera painting amongst our English painters? Much of the choicest quality of the middle school of water-colour art has unquestionably disappeared with the modern

lavish use of body colour as a white pigment. That the keeping of the paper and the using of washes of colour over its surface resulted in effects much more nearly resembling Nature's handiwork must be well assured to those who remember early works, say, of Hunt and other masters of this school. How, then, came this change of vehicle? It has always seemed that this was effected from the bad quality of the paper manufactured for art purposes. Many years ago the fault was attributed to the quantity of cotton rags then coming into use. Some thirty-five years since Creswick patented an invention for facing the commonest sort of drawing-papers with a thin layer of linen paper. This was particularly successful as to a very thin paper made by this method, but the paper was not quite white; it had a tint of not agreeable yellowness. As against the use of pure water-colour, and in favour of tempera painting, it may be stated that by the latter custom of production there is less danger from mildew than of old; that with common care in avoiding the use of glazing colours over portions of a picture laid in with solid white too hastily, the probability of permanence is added to by our new practice. Further, it seems that one or more of our vegetable colours become permanent from admixture with the Chinese white now used. The production of these works should be incomparably more rapid than could have been the case under the old system, so that it would seem that this change, resultant from the ill practices of our manufacturers, albeit changing our practice of art, has provided us with some equivalent as to durability.

A MEMOIR on the subject of the Croix Gammée or Swastika, by the Right Rev. Dr. Graves, Lord Bishop of Limerick, has recently been published by the Royal Irish Academy, as Part 3 of the 27th volume of their Transactions. Antiquaries do not appear to have published any notes on the occurrence of this disguised form of the cross on Irish monuments. But in this memoir illustrations are given of its occurrence on at least four ancient Irish inscribed stones, and on two of these, in connection with Ogam inscriptions, all of them apparently belonging to the Christian period—indeed, never yet in Ireland has it been found on a pagan monument. The author agrees with De Rossi that it is a very ancient device, which has been used as a symbol by many nations. It is to be found in the sacred books of the Persians, and was employed by the Buddhist priests. Dr. Schliemann has found it on pottery at great depths below the surface at Hissarlik and Mycenæ. It appears on coins of Palestine, Greece, and Sicily, and on gold Scandinavian bracteates, and De Rossi points to a Roman pagan monument on which it appears. "The truth is that the early Christians, finding this symbol in common use, employed it as a disguised cross in times of persecution, when, with their profound reverence for the sign of the cross they were obliged to combine a certain prudence, which restrained them from exposing the emblem of their faith freely to the view of pagans who made it the object of ridicule and reproach." Two of the stones, figured, were found near Glencar, in Kerry; a third, on one of the Blasket Islands off the coast of Kerry; and the fourth, near Minard, also in Kerry.

ON Easter Sunday, at evensong, a panic occurred in St. Peter's Church, Leicester, which created considerable alarm. The church is a new building, designed by Mr. G. E. Street, R.A., and a new ventilating door has just been placed in the tower. The church was crowded to excess, and just as the vicar was giving out his text the churchwarden ascended the tower to open the new ventilating door, which made a loud and startling noise. Just at this moment the gas was turned down suddenly, and some foolish person called out "Fire!" The congregation rose to their feet, and many rushed for the doors, on the way to which a number of ladies fainted. The vicar and some members of the congregation made efforts to quell the alarm, and the gas having been raised, a number of ladies who had fainted were carried from the church. It is stated that there was only one door unfastened and available for egress, and that all the doors are constructed to open inwardly, so that had the panic extended disastrous results must have followed. After an interval of ten or fifteen minutes the service was proceeded with, without further interruption. It is of course impossible to prevent timid, foolish, or mischievous people

from originating panics, but it is as well to provide against the inevitable consequences. From what we have seen of Mr. Street's churches, we believe practical matters such as ventilation, facilities for egress, &c., receive at his hands an amount of attention it would be well if all architects gave to them, and we are surprised to see it stated that it was otherwise with regard to the church referred to at Leicester.

THE United States Signal Service Station at Pike's Peak is the highest signal station in the world; it is also the highest inhabited portion of the globe. It is 14,336 ft. above the level of the sea. On the highest point of the summit stands the signal station—a rough stone building, 2 ft by 30 ft., one story in height. It is divided into four rooms—officers' room, kitchen, store-room, and wood-room. The station is 3 miles from the timber line, where the greater part of vegetation ceases. Short grass, tufted with delicate Alpine flowers, struggles for an existence against the frigidity of the atmosphere, and creeps towards the mountain top; but there are hundreds of acres of cold grey and reddish rocks where not a vestige of verdure exists. Like the dwellers of the arctic regions, the inhabitants of Pike's Peak have but two seasons—summer and winter: two months of summer—August and September—and ten long, cold months of winter. The summer season passes quickly. The atmosphere is congenial; the many visitors to the Peak enhance its social life with joy, wonderment, and mirth. During the summer of 1878 upwards of 900 people, in parties from five to thirty, visited the peak, among them many ladies.

THE development of a taste for art and art objects seems likely, says the London correspondent of the *Leeds Mercury*, to be marked by its destructive as well as by its conservative phase. "Hitherto we have been content to enter pleas for the protection of ancient monuments and against the modernising rage of certain restorers. We have revived the style of Queen Anne, and by precept and example have rehabilitated the Jacobean period. It would seem as if some of our leaders and art critics are anxious to carry their reforming zeal a step further, and to remove from our sight some of the monstrosities of the later Georgian and early Victorian period. It is true that such monuments as the Duke of York's Column and the equestrian caricature of the Duke of Wellington opposite Apsley House cannot be described as things of beauty, but should the new Iconoclasts once begin the work of destruction, our already bare streets and squares would be shorn of nearly every vestige of the past, from the figure of George III. taking off his hat to the cabmen in Cockspur-street to Colonel Cartwright meditating on the decay of life and morals amid the desolation of Burton-crescent."

THE largest library in the world is stated to be the National Library at Paris, which in 1874 contained 2,000,000 printed books and 150,000 manuscripts. The British Museum and the Imperial Library at St. Petersburg both contained about 1,100,000 volumes in 1874, and the relation is probably the same now. The Royal Library of Munich contains 900,000 books. The Vatican Library at Rome is sometimes erroneously supposed to be among the largest, while in point of fact it is surpassed, so far as the number of volumes goes, by more than sixty European collections. It contains 105,000 printed books and 25,500 manuscripts. In the United States the largest is the Library of Congress at Washington, which in 1874 contained 261,000 volumes. The Boston Public followed very closely after it with 260,500 volumes, and the Harvard University collection came next with 200,000. The Astor and Mercantile, of New York, are next, each having 148,000. Among the colleges after Harvard's Library comes Yale's with 100,000. Dartmouth's is next with 50,000, and then come in order Cornell with 40,000; the University of Virginia with 36,000; Bowdoin with 35,000; the University of South Carolina with 30,000; Ann Arbor, 30,000; Amherst, 29,000; Princeton, 28,000; Wesleyan, 25,500; and Columbia, 25,000.

OAK, according to a German technical journal, may be dyed so as to resemble ebony by soaking it for forty-eight hours in a hot saturated solution of alum and then painting it with a decoction of one part Campeachy wood in eleven parts water. This decoction should be first filtered and slowly boiled down to one-half its volume,

when ten to fifteen drops of neutral indigo tincture should be added to every quart. After the application of this solution the wood should be rubbed with a saturated solution of verdigris in acetic acid. The operation is to be repeated till the desired tint is obtained.

WHILE public attention is directed to the improvement of the street lighting of London (at present about the worst-lighted metropolis in Europe), "Fiat Lux" asks what is the advantage of placing the lamps on standards half-way into the street? The mean, unsightly gas-posts are convenient for catching the wheels of runaway cabs, or for a perch whence the little vulgar boy may enjoy the rare sight of a procession of any kind. But in what other way are they useful? They throw a shadow on every side, so heavy a one immediately beneath that on a gloomy night a prowling garrotter might find the lamp-post his best place of concealment. If the gas-pipes were carried up the house walls or the area railings, it would admit of strong reflectors being used, which would double the amount of light and throw it all into the public thoroughfare, collected, instead of, as at present, diffused in empty air.

THE Boston Chapter of the American Institute of Architects has, by invitation, united with the Boston Art Club and with the School of Drawing and Painting, with the object of holding a general exhibition of contemporary art in the new wing of the Museum of Fine Arts in that city. An unusually large proportion of the space available has been assigned to the architectural department of the exhibition. The exhibition is to open April 22, and no contributions can be received after April 12. An opportunity so conspicuous for increasing the public interest in works of architecture and decoration should not be allowed to pass by unimproved. It is worthy of observation, by the bye, that the general presumption that only pictures of architecture, and not plans, geometrical elevation, sections, and details, are acceptable to the public is not sustained, in America at least, by facts. The unexpected general interest evinced in the exhibition of the competitive plans for tenement houses in New York seems to show that pictorial demonstration is not the only way by which architecture can make itself interesting to outsiders.

THE opening of the Shakespeare Memorial Theatre, at Stratford-on-Avon, will be inaugurated next week by a series of festivals, commencing on Wednesday, the 31st anniversary of the poet's birth. A collation is to be provided in the Town Hall, after which appropriate toasts will be drunk, including "The Immortal Memory of Shakespeare," "The Shakespeare Memorial Association," and "The Drama." In the evening the first performance will take place in the Theatre, when *Much Ado About Nothing* will be placed upon the boards; the part of Benedict will be undertaken by Mr. Barry Sullivan, and that of Beatrice by Mrs. Theodore Martin (Helen Faucit). On Thursday evening and Saturday afternoon *Hamlet* will be performed, Mr. Barry Sullivan taking the principal character, and on Friday a miscellaneous concert of Shakespearean music will be given in the theatre. On the following Sunday, the 27th inst., sermons will be preached in the Church of the Holy Trinity, at Stratford-on-Avon, by Dr. Alexander, Bishop of Derry and Raphoe, and by the Rev. Stopford A. Brooke. The theatre, which has been erected from the designs of Messrs. Dodgshun and Unsworth, illustrated in the *BUILDING NEWS*, Sept. 15th and 22nd, 1876, has been finished, with the exception of ornamental details and interior decorations. The amount received in subscriptions has not, up to the present time, been sufficient to complete the whole of the scheme proposed by the Shakespeare Memorial Association, who have issued an appeal for subscriptions to enable them to realise the entire design, namely: in addition to the small theatre about to be opened, a library of dramatic literature, and a gallery to contain pictures and statuary of Shakespearean subjects.

OUR remarks last week on Sunday school planning have created some interest. In the "Wesleyan Sunday School Magazine," for 1876, to which our attention has been directed, we notice a series of articles on Sunday school planning by Mr. James Weir, A.R.I.B.A., who strongly advocates the radiating principle we referred to. Mr. Weir adopts a large central hall or assembly room of semi-circular form, with

circularly arranged seats and a platform in centre. Round these the class-rooms are ranged in vau-soir-like order, the outer walls retaining a rectangular form, the infants' school occupies the space before the platform,—the keystone so to speak, and the library and secretary's rooms form a small projection in front. There are separate entrances for the adult class-rooms; the class-rooms are lighted by windows in the outer walls, and the central hall from above the roof of front ante-rooms. Mr. Weir illustrates some good examples of American schools, which combine the radiatory and rectangular principles, and we shall be glad to find English architects adopting one or two of the lessons our transatlantic cousins have learnt, in economy and classification of arrangement.

ECCLESIASTICAL antiquarians will read with interest in the current number of *Scribner's Monthly* the account of a ruin in Newport, R.I., a very beautiful watering-place in America. It is a roofless, cylindrical, stone wall, about twenty-five feet high, like the remains of a round tower, built upon eight well-formed Norman arches, sustained by eight stout, round columns. It is built of small, broken stones, laid in mortar, generally termed "rubble work." The outside diameter of the tower is twenty-three feet, the walls are about two feet thick. The columns are ten feet in height, and three feet two inches in diameter. The arches are twelve feet six inches in height. The ruin has long been called "The Old Mill." But archeologists have now come to the opinion that it is the ruins of an ancient baptistery, and at least eight centuries old. It is thus the most ancient Christian building in the United States.

AN excavator on the pneumatic principle has just been completed by Messrs. A. Wilson and Co., of the Vauxhall Iron Works, Wandsworth-road, to the order of the New South Wales Government, for the purpose of sinking cylinders in connection with the improvements now in progress at Sydney Harbour. The apparatus, which is the invention of Mr. Reeves, the resident engineer of the Tay Bridge works, consists, according to *Engineering*, of two cast-iron cylinders, each 4ft. in diameter, bolted side by side on a framing, and both connected near the bottom to one suction 3½in. in diameter. The suction is of the necessary length for the work to be done, and has at its outer extremity a cast-iron nozzle of special construction. The delivery of the excavated soil is effected through a trap-door in front of each of the cylinders, which are also fitted with a float and gauge to indicate when they are full. The cylinders are domed at the tops, and are connected at that point by an iron pipe of small diameter, with an air-pump driven by a 4-horse power engine carried on the same framing, both the air-pump and engine being of the overhead type. On the air-pipe is mounted a three-way cock, by which either or both the receiving cylinders can be placed in or out of communication with the air-pump. The suction part of each receiving cylinder is fitted with a self-acting valve, so that either one or

the other or both of the cylinders can be used at the same time. The usual method of working is to use the cylinders alternately, that is, to fill one whilst the contents of the other are being discharged. It was largely owing to this apparatus that such rapid progress was made with the sinking of the cylinders of the Tay Bridge, its use enabling the contractors to effect a large money saving on their contract.

IN an article by the late Professor Hartt, reprinted in the *American Naturalist*, the author observes that among savage peoples generally the art of pottery making is, at first, exclusively practised by women, the reason being that the fabrication of earthenware is primarily and essentially a branch of culinary work—the latter everywhere falling to the lot of the gentler sex. Savage woman not only makes the vessels of clay, she also ornaments them, and if the fictile art has originated with her, and has grown up under her hands, it seems no less probable that the ornaments she uses should have originated with her; and the probability is increased by the fact that to her falls the work of spinning and weaving, and of making and decorating personal ornaments and clothes, and of making baskets, mats, &c. She is everywhere the primitive decorative artist, and to-day it is the exception that man occupies himself with ornamental art, even in civilised countries. Woman covers with ornament everything her hand touches, and the lady in her boudoir industriously embroiders, on some article of mere luxury, the same series of frets and scroll borders that, on the Amazon, the savage unclothed squaw as diligently and with as firm a hand traces with a spine on the damp surface of the clay vessel she is fashioning. The ornaments are in both cases identical, and not only of wholly independent origin, but it may be of very different age. Those of the savage are the mere embryonic beginnings of art life, while those of the boudoir are archaic forms, persisting through the ages, still flourishing unchanged among the varied wealth of derivatives by evolution from the ancient primary forms.

Lamplough's Pyretic Saline is refreshing, most agreeable, and the prevention of FEVER, BILIOUSNESS, SMALL-POX, SKIN DISEASES, and many other spring and summer ailments. Sold by chemists throughout the world, and the Maker, 113, Holborn Hill. Use no substitute.—(ADVT.)

CHIPS:

On Tuesday the business of Messrs. Child and Co., at Temple Bar, was commenced in a temporary building immediately adjoining their old premises at Temple Bar. The old room facing the street, known from generation to generation as "the shop," was at the same time dismantled, and is now doomed to immediate demolition in order to make room for the new banking house which will shortly rise in its place, only being thrown a few feet further back from the street. When this change is commenced, the last remaining stones of Temple Bar on the south and north sides of the street will be finally removed also.

The School Board for Sutton, Surrey, on Tuesday week elected Mr. Appleton as their architect.

The surveyors appointed by the Birmingham Free Libraries' Committee, Messrs. Martin and Chamberlain, and the assessors, Messrs. Thomas Naden and Sons, representing the Lancashire and the Yorkshire Insurance Companies, have completed their investigations, and the total amount of the damage sustained is valued at £20,063 5s.

A new Methodist Chapel at Scholes, Cleckheaton, was opened on Good Friday. The chapel has been built from plans prepared by Mr. R. F. Rogerson, of Brighouse. It is built in the Classic style, faced with ashlar dressings. On the ground floor is a schoolroom, 36ft. by 38ft., which is capable of seating 250. The total cost was £2,250.

At the last meeting of the Wakefield Town Council the resignation of Mr. Pagan, Borough Surveyor, was accepted, and Mr. J. G. Hesling was unanimously appointed Surveyor, at £150 per annum.

Mr. John Creswell, A.I.C.E., architect to the Corporation of Manchester, has been almost unanimously appointed County Architect of Northumberland. There were upwards of seventy candidates.

The Congregationalists of Colne, last week, opened their new chapel, which has been in the course of erection for the last fifteen months. The new building has cost £4,100. It will seat about 650 persons, and has been erected from designs by Messrs. Waddington and Son, architects, Burnley.

The foundation-stone of the second group of Board Schools at Guisborough was laid on Thursday week. The schools, which are intended to accommodate 1,600 children, are estimated to cost about £4,000. The architect is Mr. Bottomley, of Middlesbrough; and the building of the schools has been let to Mr. R. Cass, of Guisborough.

A new Roman Catholic church is being erected at Castlebar from the designs of Mr. J. J. O'Callaghan. It is of Thirteenth Century Gothic character, of a French type. It is built of the grey limestone of the district, with chiselled bands of red sandstone introduced at intervals in the building. Should funds permit, a tower and spire will be added rising to a height of 165 feet.

The Cork Town Council have received a report from a committee with reference to the duties of Mr. Matthias T. O. Keefe, C.E., recently appointed to the combined offices of city engineer and local surveyor, at a salary of £350 a year. The committee recommend that applications for works of improvement, &c., shall be received from any ten ratepayers, and that it will be within the province of the city engineer to suggest other necessary works; for these works half-yearly schedules and reports are to be prepared by the engineer, as well as annual reports on all roads, streets, bridges, public buildings, and public works in the borough. All works to be done by contract. It is further recommended that hock paving be substituted for macadam, and that the practice of renewing the surfaces of footpaths with gravel be condemned, and that the engineer be requested to suggest the best and most economical substitute.

A working stonemason, named John Hatton, in the employment of Messrs. J. Collins and Son, contractors, Warrington, has come into a legacy of about £80,000.

The corner stone of the new church of St. Paul was laid in Ashton-road, Oldham, on Easter Monday. The church is to seat 500 worshippers, and will cost £6,000.

Roofing Felts.—F. Braby & Co.

INODOROUS, SARKING, SHEATHING, AND HAIR FELTS KEPT ALWAYS IN STOCK. MANUFACTURERS OF PERFORATED ZINC, PERFORATED COPPER, AND PERFORATED IRON IN VARIOUS DESIGNS AND GAUGES.

Wrought Iron Tanks.—F. Braby & Co.

PAINTED AND GALVANISED, OF IMPROVED MANUFACTURE

Corrugated Iron.—F. Braby & Co.

GALVANISED AND BLACK IN ALL GAUGES, KEPT IN STOCK. ZINC WORK OF ALL KINDS.

FITZROY WORKS, 356 TO 369, EUSTON ROAD, LONDON.
HATTON GARDEN, LIVERPOOL. GREAT CLYDE STREET, GLASGOW. AND AT CYPRUS.

THE BUILDING NEWS.

LONDON, FRIDAY, APRIL 25, 1879.

THE INSTITUTE OF PAINTERS IN WATER-COLOURS.

THE exhibition just opened to the public at the Institute of Painters in Water-Colours, in Pall Mall, is more than usually full of works by well-known artists, though these are not of high interest or exceptional quality. The growth of a school distinguished by the use of a vehicle resembling in its solidity of effect that of oil is very apparent to the close observer of the pictures in this year's gallery, a very large portion of which are coloured with thick pigments. That this is a gain we have before expressed a doubt, as the essential character of water-colour painting is lost in thick body effects, and the decision of touch required by the old system of clear transparent washes of colour on white paper is lost. Those who admire the drawings of Prout, Cattermole, Hardy, of Hunt, or any of the school of old water-colour painters, some of whose works may now be seen in the South Kensington Museum, will value most the simple renderings in colour by those conscientious disciples of their art who have adhered strictly to its principles. In the exquisite renderings of landscape, such as Mr. E. M. Wimperis's "A Rough Common" (18), or Mr. Whymper's "Woods at Wotton" (155), we come across pictures in which the artist has boldly upheld the distinguishing qualities of transparent colouring. One of the most striking sea-pieces in the gallery is Mr. John Mogford's "Rosy Morn" (7). The sea is alone a fine piece of study; the reflections of the clear sky on the waves are cleverly produced by the local tint, without a particle of Chinese white or any body colour; the little creek, with its glassy calm rippled only by the breeze, catches the misty light of the roseate sky; the rocky cliffs with the castle, and the foreground masses are equally truthful, and the whole effect well sustains the title. There is just that hazy effect indicative of a fine calm morning by the seaside. Near it is a finely painted picture by Mr. E. G. Warren, called "The Mid-day Meal in the Harvest Field," but the handling is of a very different kind. The corn-sheaves are modelled with great care, but the near trees are a trifling finical in manner. Mr. Louis Haghe, the president of the Society, contributes as usual some masterly architectural pieces—we cannot call them sketches—as they have all the appearance of finished oil paintings. The "Interior of the Church of St. Gomar, Lierre, Belgium" (12), is a well-known subject. Mr. Haghe has produced it with all the force and feeling of which he is the master. We cannot overlook a slight crippled appearance in the arcade, the nearer curves of the arches at their points being wanting in fulness. The elaborate screen of late Flemish character, the reflected light and delicate half-tints on the round pillars, are all delineated with masterly effect. In the high lights body-colour is used, and the other drawings we shall refer to by-and-by have almost the solidity of tempera. We must not pass by a cleverly drawn coloured sketch called "A Pinch of Snuff" (10), in which Mr. Seymour Lucas has given a study of Georgian costume; the attitude, and swallow-tailed silk coat, cocked hat under arm, are thoroughly suggestive of the dandyism of the 18th century. In No. 14, "Moel Siabod," that favourite Welsh theme, Mr. O. Vacher contributes a warm-toned mountain effect, rich in body-colour and scumbled effects. Mr. Small's piece, "On

the Road to Falkirk Tryst" (17), lays no claim to water-colour; it is strictly a tempera painting. The water below the bridge is obscure and smudgy, and there is a thick and unpleasant effect. No. 16, "Which will be old maid?" a party of girls playing cards, is somewhat stiff and formal; the coiffure of the young ladies, the short-waisted dresses and sashes, are a sentimental reproduction of old-fashioned dress that seems to be running just now in the heads of artists; even the execution affects the old style. Mr. A. Bonvier's "Nydia" (20) is founded on Bulwer Lytton's "Last Days of Pompeii." The figure is graceful and poetically conceived, but the upper limb of the arm, partly exposed, is unquestionably too long, and the drapery is poorly drawn. Mr. H. G. Hine is as happy a delineator of the calm and softer character of landscape scenery as Mr. Wimperis is of the rugged and wilder beauties of nature. The latter generally chooses wild or desolate commons, marshes, and rocky mountain effects; his handling is rough and vigorous, and in admirable keeping with the subject. Mr. Hine, on the other hand, depicts with great tenderness the smoother features of pastures and downs and lakes, and his "Autumn Evening on the South Downs" (27) is one of his favourite themes. The long shadows of the declining sun and the prominent swellings of the undulating downs that catch the light are admirably truthful in colour. Mr. Collier's "Wide Pastures" (38) is a piece of similar character: the deep hollow with sheep is cleverly managed as regards the shadows. "Plover Church, Cheshire" (36) is a quaint little bit of interior, showing an interesting timbered roof, with curious cut chancel screen of late design; Mr. J. Fulleylove has done justice to it. But we come to another of Mr. Louis Haghe's fine interiors in No. 40, "Interior of the Cathedral of Sienna." This Romanesque building does not lend itself so well to the artist as the last-named by Mr. Haghe. The red-striped pillars are detrimental to that breadth of effect so conspicuous in the Belgian Church. In this work the artist has not been so careful in detail, the arches are not faultless in perspective, and the best parts of the drawing are the rich cornice over the arcade filled with sculptured heads, and the medallion heads in spandrels. The church has a blue star-spangled vault. Mr. Edwin Hayes, R.H.A., is a powerful painter of sea and atmosphere. His picture, "A Signal of Distress in the Offing" (42) is a splendid example of tempest-tossed sea and misty cloud. The boat putting off to the disabled ship, the broad colouring and drawing of figures, the crowding round the jetty make a picture worthy of a Turner in conception and execution. "The Reckoning" (47), by Mr. Townley Green, is an incident which would, if painted in modern costume, be commonplace and uninteresting enough, but the artist has chosen the more picturesque surroundings of an inn as they existed a century ago. Two gentlemen are seated at a table, and have finished their repast; one is asking for an explanation of the bill which he has in his hand. The accessories of the room, the coloured coats and embroidered vests, the cocked hats and wigs of the guests are tellingly introduced, and the grouping is admirable. Mr. Orrock in 54 depicts a wild mountain scene in the Isle of Skye. The blackness of mountain, the rolling clouds and misty distance, are solidly painted, though, withal, too sublime to be pleasing. Near it, a small picture, a lady and little girl at prayers in St. Mark's, Venice (56), is feelingly drawn. No. 57 is rich, but garish in colour; the blossoms of the rhododendrons, and the oak table, are striking in their reality. Mr. P. F. Poole's "Crossing the Brook" is scarcely equal to the artist's reputation, though the drawing

is truthful, and the figures balanced and expressive. In "The Forbidden Room" (68) Mr. John Fulleylove gives a charming bit of drawing and colour; the old-fashioned, wainscotted room, and the painted piano, and the little girl who has entered clandestinely, and looks around half-timorously, are feelingly painted. Mr. W. Wilson, in "Mischievous Float" (74), portrays an amusing incident in his usual lucid style. The group of urchins who have got into a boat, and are trying to row, and the little fellow leaning over the stern, attempting to sail one of his boots, are clever in drawing and colour: but the chief merit is the marvellous liquidity of the rippled water, and the gleaming, limpid effect of the colouring. "In Sunshine and in Shade" (82) there is a keen and delicate sense of the bucolic sentiment; the grand beech trunks, with their leafy shade, and the rich, sunny peep of bright corn-field beyond, are painted with great, almost excessive, care, but the shadows lack transparency and breadth. No. 91, "Interior of the Hall of Justice, Bruges," by the late J. Chase, is an admirable but common subject. The drawing is minute almost to painful excess. The black marble fireplace, with its white frieze and carving, and the elaborate chimney breast, are too mechanically rendered to do justice to this fine example of Renaissance. Mr. C. J. Staniland's "Repose," a child asleep in its cot with a ball in its hand, is pleasing. No. 105, "Steephill Castle, Ventnor," by Mr. E. Hargitt, is a fresh bit of colour. The deep blue sea shadowed by the sunny, verdure-clad cliff, makes a pleasant sketch, admirable in drawing and light and shade. One of the most remarkable pictures is No. 109, by Mr. E. Henry Corbould—"Jehu on his Way to Jezreel." The artist here has attempted to depict the "furious driving" of the grandson of Nimshi. Mr. Corbould has chosen the period at which Joram sends a horseman to Jehu with the inquiry of peace, and Jehu points the horseman behind. The dress, chariot, and trappings, the horses and furious driving, and the distant watchtower of Jezreel display unquestioned archaeological resources, and the painting is rich in colour. The stippled manipulation of the artist has produced an oil-like depth of tone. Mr. L. Haghe's "Hall of the Brewers, Antwerp" (130), we think we have seen before. The grouping of the figures in the picturesque costume of the burghers, the stamped gold leather of the walls and the rich colouring make a pleasing picture. A very striking work is Mr. C. Green's "Bartholomew Fair" (132), in which the artist has graphically depicted a fair of about seventy years ago. In the background we see the erections of itinerant showmen, with the stock paraphernalia familiar to our youth. Organ-grinders and clowns are engaged in front of their shows, inviting a motley crowd of sightseers. We see the dandy of a past generation, escorting two fashionably dressed ladies of the time through the assemblage, card sharps, cheap-jacks, and a variety of other frequenters of fairs, but the most marvellous part of the picture is the expression of countenance, the delineation of characters, and the bright colouring. Mr. J. D. Linton's "Early Scene in 'Gil Blas'" is an episode which will be familiar to the reader of that romance; the expression of the young man at the table, and the scheme of conception and colour are excellent, though the dramatic power of Mr. Linton's work is equally well conveyed in his other picture, "False" (138). Another of Mr. Haghe's pictures, "Church of San Martino, Rome" (135), shows a fine vestibule, through which a view of the interior of basilica is obtained. The processional group introduced makes a picture of a piece that is rather too coarsely drawn to be called an architectural drawing. Contenting ourselves with this rapid glance at the principal

pictures, we have only space left to point to a few others that we have noted. In 142, "Rose Bloom," we have rather a weak conceit, a fair-haired girl amid a bower of rose-blossoms; Mr. G. Kilburne's "Visit to the Studio," is an ordinary incident painted with much feeling; No. 152 is tender in sentiment and cleverly coloured; and Mr. Absolon's episode from "Bleak House" called "Mrs. Baquet" 169, must be allowed to be more clever in execution than in conception. Of landscapes "Southwold, Suffolk" (21) is bold; No. 44, "The Toy Seller," is a bright bit of colour without much aim; Mr. Clausen's "End of the Day" 50, is painted with much feeling; "Water Carriers of the Nile" by Mr. Guido R. Bach, rich in expression and colour; while Mr. L. J. Wood's pieces, such as 53, "Münden on the Weser, Hanover," and No. 163 are picturesque studies of architectural subjects rendered in the artist's well-known style. In the last named there is a tendency to become mechanical, and the foregrounds of Mr. Wood's pieces would all be improved if they were coloured with more vigour and solidity. No. 129, "The Tay from Kinnoull Hill," is a fine piece of river scenery. Nos. 112, 117, 121, 139, 141 and 170 are noteworthy. The screens are rather devoid of interest, though we note No. 174 and 184, both clever studies by Mr. F. J. Skill, also a small but well studied piece, "The Author," by Mr. A. C. Gow; "Under the Mid-day Sun," by Mr. Hubert Herkomer, and 206, by H. B. Roberts. Flowers, as usual, make up some charming bits of colour, and Mrs. Duffield and Marian Chase sustain their reputation in these departments of the art.

LIGHT AND AIR.*

ANY means of estimating the injuries produced by the deprivation of light and air, such life and health-giving elements in our large towns, must be welcomed as one of the most desirable objects of practical legislation. Mr. Banister Fletcher, F.R.I.B.A., has just published a text-book for architects and surveyors upon this somewhat difficult and obscure branch of the architect's practice, and how far he has succeeded in divesting the subject of mathematical theory, and giving a practical exposition of the matter, will be seen as we proceed. It may be unnecessary to inform our practical readers, that two scientific theories at present exist upon the subject of estimating the amount of obstruction: one is that propounded by Mr. Homersham Cox, and to which we have before referred in the BUILDING NEWS, a method which estimates the amount of obscuration made by obstacles of uniform angular width and height, measured by degrees horizontally and vertically from 5° to 90°; the other proposed by Prof. Kerr, some years ago, and which assigns certain lighting values to the surface of the sphere supposed to represent the lighting power of a window; both of which systems we may observe have not met with universal acceptance in the courts of law. Mr. Fletcher dismisses them at once as only worthy of study by the theorist, and observes they have been "rejected, as being too complicated, and not practical." We are quite ready to admit that, after all, common sense and judgment must be brought to bear upon the subject of estimating obstructions to light, and that, as long as courts of law have these questions to decide, evidence will have far more weight than mathematics. At the same time, we cannot be brought to think that some principle of measurement is not the right and rational mode of determining a large proportion of cases, nor to believe that the courts will reject a scientific

method of calculation simply because it is rather complicated. But let us pass on to the author's treatment of the subject. The book is divided into four parts. Part I. treats of the historical aspect, Part II. of the legal definitions of light and air. Part III. treats of the methods proposed for estimating the injury; and Part IV. indicates the course the surveyor should pursue in preparing his case. This division may possess some advantages, though it would have been better if the methods proposed for estimating the obstruction of light were placed first. We shall, accordingly, begin with Part III., in which Mr. Fletcher deals with the methods proposed, and the reason why a mathematical method is not desirable. The case of "Theed v. Debenham" is cited as an important case to show how little the angle of 45° can be relied on, and we may briefly mention it as one of practical interest. The bill was filed in 1875 by William Theed, sculptor, against Messrs. Debenham, merchants, of Wigmore-street, who intended to raise the height of certain premises in Mill Hill-place, whereby it was alleged by the plaintiff he would suffer material diminution of light, and would be deprived of not only a "direct light, but what is technically termed an under or low light"; and the bill prayed that the defendants might be restrained from erecting or constructing any building at, upon, or instead of the said premises. "A point of law was raised which turned upon the distance from each other, and height of the respective buildings. It was admitted that the width of Mill Hill-place from wall to wall was 31ft.; the height of the defendant's old building, No. 1, was 29ft. 3in., and of No. 2 31ft., from the foot pavement to the parapet. The defendants intended to raise their new buildings so that their new parapet would be 38ft. from the pavement, and their new ridge of roof about 7ft. above the new parapet." The centre of Mr. Theed's window and studio was about 13ft. above the pavement. The plaintiff's lights were all ancient, but their windows had been enlarged within 20 years from the filing of the bill. It was contended for the plaintiff that a clear uninterrupted horizontal light was necessary, and that a vertical light was not sufficient, a north light being considered preferable to any other. The defendant's eaves was just as high as the width of the street, and therefore Mr. Theed had an angle of 45°, and the defendants claimed to build to 45°, measured from a horizontal line drawn through the centre of Mr. Theed's window. We may quote that part of Vice-Chancellor Bacon's ruling that bears upon the case: "I take it, therefore, that it has been proved that there will be, if the defendant's buildings are carried up to the height they propose, a serious diminution of the light required by the plaintiff for the purposes he has mentioned, and which he has hitherto enjoyed." And after further observations on the test which had been adopted, of raising a screen to the height of the proposed new building, and letting it suddenly fall, whereby, in the judgment of the court, a very satisfactory illustration of the effect of the proposed change had been afforded, his lordship continued: "One of the witnesses has a notion that if the light is not interfered with to the extent of more than an angle of 45°, the right to obscure one's neighbour's light to that extent is a right which anybody may assert against the owner of any light which is already obscured to a lesser extent. He says in effect: 'I can raise the building to this height. My building obscures you to the extent of 30° only before, I will now obscure you to the extent of 45°; that is enough light for you, and with that you must be content.' . . . The regulation as to the angle of 45° is to be found, I believe, only in that provision of the Metropolis Local

Management Act, in which the width of street is spoken of, and which of itself, measuring the width of street and the height of house, furnishes an angle of 45°. That, be it observed, is from the street, for the statute enacts that in determining the height of such building the measurement shall be taken from the level of the centre of the street; and that must be so, because the position of the windows is so different in various buildings that if you were to search for the point from which to measure your angle of 45° it would be as various as the buildings to which it would be applied." The Vice-Chancellor declared there was no rule about 45°, and thus confirmed Lord Selborne's decision in the City of London Brewery Co. v. Tennant, and said that the plaintiff had proved a statutory right to the enjoyment of his light undiminished. Injunction was therefore granted. The above cited case is a very important one, as it sets at rest much uncertainty and ambiguity regarding the angle of 45°. The author next sets forth a table by which we can estimate damage or injury to ancient light, and, we may observe, this tabular mode of dealing with the subject is preferable to a lengthened statement. We will extract the table *in extenso*:-

MATTERS TO BE CONSIDERED IN ESTIMATING DAMAGE TO ANCIENT LIGHT AND AIR.

1. Quantity of daylight lost. This should be estimated at different periods of the year, because the value of light will differ. For example, take an office in the City. The loss of daylight in the summer when probably it would be after office hours would be of little consequence; but the loss in winter, when it would occur during the office hours, and would thus necessitate the inconvenience and cost of gas, would of course have a different value.
2. The particular use for which light is required, having regard to the fact, that for certain trade purposes, no amount of gaslight can be a substitute for daylight.
3. If for all the time it has existed it has been used for the particular purpose; if not, for what other purpose?
4. How far the enjoyment of the premises is affected.
5. How far by alterations of dominant owners' premises, the diminution of light may be avoided. In case this can be effected, it will be necessary to make a careful estimate of the cost of these works and the quantum of inconvenience they would occasion the dominant owner. This may be set out in the defence, and may influence the jury in assessing the damage; but it must be remembered in law the dominant owner cannot be required to alter his premises.
6. Whether the quantity of light and air is so far diminished as to render the room unhealthy for occupation.
7. How far the injury to dominant owner's premises may be reduced by the use in building servient owner's obstruction of white glazed bricks or facing it with white tiles or other material.

These heads of considerations embrace the chief points the surveyor has to consider. No doubt such a variable thing as light enjoyed under such very different conditions of atmosphere and necessary to different occupations in varying degrees is a very difficult matter to compute. Whenever an action has to be sustained it is necessary to prove a material diminution of light, and the author's advice is admirable in its way where the surveyor is enjoined to "free himself from party ties and look at the matter as a practical man"; but still we contend a method of estimating obstruction is useful as a guide—as a test. For instance, one surveyor or witness may be both practical and honest, and yet estimate a certain obstruction at a very different amount to another equally practical surveyor. Under such circumstances, how is a fair assessment of the damage to be made unless with the aid of some such method as that proposed by Homersham Cox? Mr. Fletcher, in the diagrams appended to his book, himself affords evidence that the court is more ready to take palpable proofs of the amount of obscuration produced by front, lateral, or skylight obstruction than it would *vis à voce* evidence of a conflicting character. The

* Light and Air. A Text-book for Architects and Surveyors. BY BANISTER FLETCHER, F.R.I.B.A., &c. B. T. Bateford, High Holborn, W.C.

author's comments on the items given above are practical and to the point; thus, as to 3, it is necessary for the surveyor to know if the premises are adapted for other besides the present purpose. The ruling of Vice-Chancellor Bacon we have above quoted favours the dominant owner, for he says distinctly the light which he enjoys is no more to be tampered with or taken away than the front wall of his house, and no man can be heard to say he may obscure another's ancient light because he has more than he requires. As to the enjoyment of the premises, it has been ruled by Lord Justice James that the amount of light, to be sufficient, should be according to the ordinary notions of mankind, "for the comfortable use and enjoyment of the house as a dwelling-house."

We pass on to notice the diagrams introduced to explain the amount of obstruction. These are supposed to represent the upper half of the windows, the view being taken with the eye 5ft. 3in. from the ground, and the body removed back one foot from the window. The field of view is divided into squares, and in one diagram the state "as it was" is shown, while another similar area shows the obstruction. By drawing the new buildings by the aid of the squares, the loss of sky or light is estimated approximately at a percentage of the whole area. Front obstructions are similarly shown, though in this case the area of the whole window may be sketched. In these the views are taken from the first-floor window with the eye at a height of 5ft. 3in. from the floor, and the body 1ft. from the window. From the ground-floor window the loss of light is of course greater, and sometimes total. The object of these drawings may be to show either that the slightest diminution is a great injury to the dominant owner, who may have very little light or sky above the opposite houses, or by the servient owner, that the premises are already so obscured that a little less cannot make any appreciable difference. Another kind of obstruction is called by the author a "distant lateral," or where a row of houses at right angles to the plaintiff's house, and on one side of it, are raised. In the case cited, the plaintiff contended that the raising of the houses made his house unhealthy from the loss of the sun's rays; but the author proved, by visiting the premises at different periods, and making diagrams of the effect of the sun on the house-front, that they did not overshadow the plaintiff's house. The last case illustrated refers to skylights. Here the view is taken looking upwards through the skylight, showing in one diagram the sky "as it was," and in the other "as it is" after the obstruction, the new building being drawn thereon. It often occurs that a shop lighted by a skylight is over-shadowed by raising an adjoining building, and such a case is shown by the author. A section is a necessary diagram in this case, to show the actual loss of rays suffered. In the frontispiece the lost rays are indicated by lines in red, the rays still left by blue. It may be necessary, for instance, to show that the raised wall obstructs the most useful light, as, for example, that on one side of a dispensary where medicines are made.

Having devoted a considerable portion of this article to the exposition of that part of Mr. Fletcher's text-book relating to the estimation of obstruction, we may now very generally glance at the other parts. These refer to the historical and legal aspects, with which our readers are probably better acquainted. A comprehensive synopsis of the leading definitions and cases we published last week under the head of "Light and Air," written by Mr. Jas. Ball, and we shall therefore confine the reader's attention to the main features of Mr. Fletcher's treatise. The author quotes very largely from the legal authorities in the matter, and we find the paper of Mr. Locock Webb, read at the Insti-

tute of British Architects, and reported fully by us, has been consulted. There are some injuries sustained by servient owner for which the law provides no redress, such as the diminution of the value of a house caused by its windows being overlooked, and the privacy of the house destroyed. Mr. Fletcher refers to three cases of this kind, and we might mention several others within our own experience. It is a kind of encroachment of daily occurrence, and in view of it the professional adviser should be particularly on his guard in recommending building or purchases on estates. How often a beautifully retired garden is overlooked from a row of tenements erected by the speculative builder; but no court of law will interfere on the mere ground of an invasion of privacy. Table II., given, shows how the right to light and air is acquired. 1. By continuous use for 20 years. 2. By express grant. 3. By implied grant. And (4) by a dominant and servient ownership, distinct from each other. The author cites several important cases bearing upon these items. As to the time, it is necessary to observe that, although twenty years is necessary to acquire the right, "yet, should any one take steps to contest it by erecting obstructions, nineteen years and one day will defeat the attempt." The difficulties of proving an implied grant are discussed. Table III. shows that neither non-completion of building nor non-occupation interferes with the right, a fact of some importance in many cases where the enjoyment of the premises has not extended to the whole period of 20 years. In the celebrated case *Tapling v. Jones*, we have the fact that ancient light may be imperilled by alteration or by variations. This case is quoted in full. Alterations of the plane at which light is admitted, the occupation by the dominant owner of the servient owner's premises, and ownership of both properties in the same parties, may severally jeopardise the right. Table V. shows that ancient lights may be lost "by servient owner obstructing for one year, by agreement between dominant and servient owners, or express release, and by abandonment." The last part of Mr. Fletcher's work is headed "The Fight," in which the author discusses the method of defending the client's rights, and what the respective surveyors may try to prove. These, of course, in effect, comprise the points already mentioned, and the author explains every item *seriatim*. A few useful hints in a tabular form are given, and the advice on the selection of counsel, skilled and other witnesses, will be found of practical guidance to members of the profession who may have a case of light and air placed in their hands, and who may wish to know the usual tactics made use of by the opposite side. The tables are a good feature in all Mr. Fletcher's handbooks, and the practical man will find them useful for ready reference. In the selection of cases and citations, perhaps a little more method might have been observed, and if the reports and rulings had been more condensed by the omission of a deal of unnecessary repetition, the book would not have lost in value. As we have hinted already, we should have liked a little more prominence to have been given to the methods of measurement, impracticable as they are considered, if only for the study of the surveyor, who must be supposed to be acquainted with the mathematical modes of determining the amount of obscuration. Notwithstanding, Mr. Fletcher's text-book is by far the most complete and practical we have seen, and the professional architect or surveyor who may be called in, either by dominant or servient owner, will do well to fortify himself with it, for he will find the *crème* of all the legal definitions and decisions he is in need of, and a practical exposition of at least one mode of determining the amount of injury inflicted. The work has a good index.

ARCHITECTURAL MOSAIC.

VI.—MODERN MOSAIC (*continued*).

IN no department of the art does modern mosaic show so decided a superiority over the ancient than in ceramic work, that is, work where the mosaic fragments are composed of earthenware. Its tesserae are harder and capable of enduring much more severe wear and tear; they are made in a far greater variety of colours, which afford scope for greater elaboration of ornamental design, while the brilliancy and polish of many kinds are not below the brightness of glass mosaic itself, and make it possible to employ the modern ceramic mosaic for wall decorations—a purpose for which, so far as we can remember, the ancient kind was seldom employed, being used almost exclusively for pavements. And the reasons for this superiority are not far to seek. In the first place, the ancient ceramic work was practised only as a provincial or colonial art, at a distance from the centre of the Empire. Nearer home, in Italy and in Greece, there was for a long time a plentiful supply of marbles, and afterwards, when that began to fall into disuse, glass mosaic arose. But in the provinces of the great Empire, when a Roman magnate desired to adorn his house with pavements resembling those of the imperial city, he was obliged to use such substances as he could find ready to hand in his adopted country for the materials for his tesserae, and to depend upon provincial workmen both to manufacture them and lay them down. Hence it follows that while the designs have all the merits—and demerits be it also said—of other branches of ancient mosaics, the ancient ceramic tesserae are mostly comparatively soft and perishable, the preservation of such as have remained to this day being due to accidental causes. But the modern ceramic work is practised under widely different conditions. Instead of being employed only where marble or glass was unattainable, it took its place in the modern revival as substantive mosaic, and being for a long time the only kind practised in this country, its improvement and development has been the constant study of several of our most enterprising manufacturers and our most accomplished artistic architects.

The following is a brief account of the successive improvements which have taken place in the manufacture of the tesserae:—The first modern mosaic pavements were those of Mr. Blashfield, briefly referred to in our opening article, which consisted of cements or bitumen coloured with metallic oxides, which stood exceedingly well under cover, but were found upon experience not to endure the severity of winter frost. These were succeeded by Mr. Singer's method of forming tesserae from thin layers of clay, previously prepared and stained of the desired colour, which were cut into long narrow strips or ribbons by means of a squeezing machine. These ribbons were then cut into squares, which were piled one on another fifteen or twenty high, being previously oiled to prevent adhesion, and then placed upon a frame sliding in two perpendicular grooves, with fine steel wires stretched tightly across, so that by pressing the frame downwards the wire sub-divided the slices into the square, oblong, triangular, or other shaped tesserae required, which were then dried and baked in the ordinary way. Tesserae prepared in this manner, however, would not be more enduring than ordinary earthenware tiles, and if artistic designs were to be employed worthy to last for ages it manifestly became desirable to find a more imperishable material, and this was happily found in the application of Mr. Richard Prosser's "dry process," originally invented for the manufacture of buttons, and which is now, with certain modifications of details, used by all our great manufac-

turers of mosaic tesserae. In 1840 Mr. Prosser discovered that if the material of porcelain (china clay) be reduced to a dry powder, and in that state compressed between steel dies, the powder is condensed into about a fourth of its bulk, and is converted into a compact solid substance of extraordinary hardness and density. Previous to this discovery the power which the hand of the potter exercised over his clay, and which had been proverbial from time immemorial, was limited to clay in its moist or plastic state, but by the new process the necessity of using wet clay is altogether avoided. The earthy material, after being prepared in the usual manner, and brought to the plastic state, is formed into lumps, which are dried until the water is evaporated from the clay. The lumps of dried clay are then broken into pieces small enough to be ground by a suitable mill into a state of powder, which is afterwards sifted, in order to separate all coarse grains and obtain a fine powder, which it is desirable should consist of particles of uniform size as nearly as can be obtained. The powder, so prepared, is the state in which the clay is ready for being moulded into the form of the intended article by the new process. The machine and mould used for moulding the tesserae, is to a certain extent an ordinary screw press, such as is commonly used for cutting and compressing metals for various purposes, but furnished for this manufacture with a hollow mould, formed of steel, the exterior cavity of the mould being the exact size of the tesserae to be moulded. This mould is firmly fixed on the base of the frame, so as to be exactly beneath the lower end of a piston or plug, which is adapted to descend into the hollow of the mould by a screw action, the plug being very exactly fitted to the interior of the mould. The bottom of the mould is a movable piece, exactly fitting the interior, which lies at rest during the operation of moulding, but is moved afterwards by means of a pedal, so as to deliver the article moulded. The operation is extremely simple; the operator first with his right hand raises the plug by means of the screw, quite out of the mould, while with his left he scrapes laterally, from the table near the mould, a small quantity of the prepared powder into the hollow of the mould so as to fill it completely and exactly. Then a turn of the handle brings the plug gently but firmly down upon the loose powder with a great force, which compresses it into about one-third the space it occupied in a loose state. The bottom of the mould is then raised and the tesserae delivered from the top of the mould, when it is found to possess sufficient coherence to enable it to endure as much handling as is requisite for placing a number of them in saggars ready for firing in the kiln. By this process the great contraction which takes place in drying articles that have been moulded from clay in the moist state is altogether prevented, and consequently all uncertainty in the extent of that contraction is avoided. The tesserae are extremely hard, and pavements constructed with them excel the finest works of the Romans in form, in colour, and every other mechanical condition.

The above process was very early introduced to the firm of Minton and Boyle, of Stoke-upon-Trent, by Mr. Blashfield and Mr. Prosser, and the late Mr. Herbert Minton took a lively interest in it, the first tesserae for mosaic work being made at his works in August, 1840. Progress was slow, however, until March, 1843, when a paper by Mr. Blashfield was read before the Society of Arts, and the process of making the tesserae were shown by Mr. Turley, the engineer to Minton's, 290 boxes of buttons, with 3 dozen in each, being given away at the doors. A second exhibition of the kind took place a few days afterwards at the house of the Marquis of Northampton, President of the

British Association, at which the Prince Consort and a most distinguished audience were present. This lecture led to the Prince taking a great interest in the manufacture, and henceforth its success was rapid and assured, the patent being worked until its expiration by Messrs. Mintons alone.

But great improvements in another direction have been also effected by the enterprise of Messrs. Maw and Co., of Bentham Works, Broseley. After the establishment of their works at that place in 1852 they spent several years in a series of costly experiments, with no immediate profit, but they gained experience by which they subsequently profited largely. Their first effort was thoroughly to investigate and experiment upon all the clays of the Staffordshire field, as well as the plastic materials found throughout the kingdom, many of which no one else had before attempted to turn to economic account. The results of these experiments have been illustrated in an extensive series of specimens of the clays or plastic slates of Great Britain, presented by Mr. George Man to the Government Museum of Practical Geology in Jernyn-street, and described in a supplement to the catalogue by Sir Henry de la Beeche and Mr. Trenham Reeks. In 1857, after all these years of patient labour, they commenced the manufacture of tiles and geometrical mosaic on a commercial scale, since which time their progress has been continually marked by the grafting on of new specialities, the yearly production of new colours, and new phases of ceramic art applied to tiles. From the first they laid themselves out for applying the very highest art and architectural talents to their manufactures. In 1856 they published a small volume of designs for geometrical mosaic by Sir M. Digby Wyatt, and in 1867 a much larger volume, which included the designs of such eminent men as Sir M. D. Wyatt, George Edmund Street, J. P. Seddon, J. Burges, Geo. Goldie, and others, as well as reproductions of all the best obtainable examples of ancient tiles, geometrical and Roman mosaic, &c. In 1861 they commenced the manufacture of very small tesserae for the formation of pictorial mosaics, and produced for the Exhibition of 1862 their well-known mosaic of "The Seasons," which is now in the South Kensington Museum, from a design expressly made for them by Sir M. Digby Wyatt. The result of this work was so satisfactory that the firm was afterwards commissioned to execute a mosaic frieze for the inner quadrangle of the new India Office at Westminster. Among the more recent productions of Messrs. Maw may be mentioned tesserae for mosaic work, decorated with rich enamels.

With all these improvements, modern ceramic work enters upon a by no means unequal competition with marble and glass work, as is forcibly illustrated by the splendid series of portraits of artists in the Architectural Court at South Kensington. Out of the whole series of thirty-five pictures no less than eighteen are in English ceramic work by Simpson and Co., Minton and Co., and Minton, Hollins and Co., and these are placed side by side for comparison with the Italian glass mosaic of Salviati, and English glass mosaic by Harland and Fisher, Rust, and Powell and Sons, where the colours are every whit as bright and the general effect quite as good as in the other material, except, perhaps, the gold ground, which is not quite so sparkling and transparent. The most considerable out-door work yet performed with ceramic mosaic in this country is the so-called "permanent fresco" in the great frieze of the Albert Hall, in London. This was executed with Messrs. Minton Taylor's cubes, and the effect is very pleasing and satisfactory. When its permanence is considered, the cheapness of this kind of exterior decoration

ought certainly to form a great recommendation. This whole frieze, containing 5,200 square feet, cost £3,444; but about £3 per square yard is about the average price for coarse out-door work, although some coarse work can be done for as low as 30s., whilst others will run to £4 or £5.

The process of combining ceramic tesserae into the design required is as follows:—

A careful tracing of the design having been made, portions in reverse of about 50in. square, are distributed to the assistants employed to execute the work. With the original before them, they set the various tesserae required to make out the design; at first loose, but afterwards, when a portion is accurately completed, dipping the face of each into gum, in order to make it adhere to the paper. The several portions so completed are then put together, with a wooden border forming a shallow trough round them, into which the Portland cement is poured, which sets the whole. The paper is then removed from the face, and when necessary, an iron band is placed round the work to bind it stronger together.

Tesserae are formed into paving slabs thus. Laid face downwards, on a perfectly flat slate, in the pattern or design required. Size and shape of the slab is given by strips of wood or slate fastened round the tesserae. Portland cement is poured on the backs of the tesserae, and two layers of common red tiles are added in cement, thus forming a flat and strong slab, which is fitted for laying down as pavement.

The better tiles and the larger tesserae for pavements are laid separately, on a carefully prepared foundation of fine concrete, and then set in fine sand.

Another process, the invention of Mr. Minton Campbell, is an attempt to combine the mechanism and durability of mosaic with the freedom of oil painting. It consists in the preparation of a surface composed of tesserae of a hexagon form, held together by potter's flux. The extent of this surface may be either that of the whole picture or of any portion that may be desirable. This surface is painted with vitreous colours by the artist, and the whole is formed into one mass by the usual process of baking. Its advantages are said to be that an unlimited variety of shades can be obtained without the heavy cost of ordinary mosaic. Specimens of this work may be examined by the students on the grand staircase of the ceramic gallery at South Kensington, but it can hardly be called true mosaic, as the joints of the tesserae are almost entirely concealed by the thickness of the painting and the operation of the flux.

In estimating for mosaic, as for everything else, it must be reckoned that there are masters in the art, who can always command superior prices, as well as ordinary workmen. The cost of work also will be much affected by the number and variety of figures introduced into the design, which occupy more time and require higher skill than plain work. The variety of colours also affects the cost, some colours being more difficult to manufacture than others; reds and purples are the most expensive, but gold and silver mosaic, especially silver, are more expensive than common tints. It is not far from the average to say that gold and silver tesserae are about double the value of coloured. The cost of the cartoon also must be added to the account, and it may prove a considerable item when designed, as it should be for important works, by an artist of eminence. In estimating the general cost of decorating the interior of St. Paul's with mosaics, a few years ago, Mr. Penrose calculated that for work at 40 or 50ft. from the eye, where fine work was unnecessary, 25s. per foot would cover the entire cost, including plaster work, and everything, but that the spandrels, each containing about 270ft. of finer work, would

cost about £500 each. The portraits of artists at South Kensington contain about 3sq. yards each, and their average price was about £140, which however did not include any payment to the artists for designs. If we could capitalise all the amount which has to be spent for repairs, repainting, and cleaning of other kinds of decorations, it would appear that although the first cost of mosaic is somewhat higher, its permanence, and fadeless brightness, would render it really cheap in the long run.

OIL AND WATER-COLOUR PAINTINGS AT THE GERMAN ATHENÆUM.

AT the German Athenæum in Mortimer-street, Regent-street, a choice collection of paintings and drawings is to be seen, which will remain on view till the 5th of May. The works comprise pictures and studies by L. Alma Tadema, A.R.A.; Guido Bach, J. W. Bottomley, Carl Haag, Hubert Herkomer, Sir F. Leighton, P.R.A., E. Long, A.R.A., Edward J. Poynter, R.A., B. Riviere, Dante G. Rossetti, S. F. Watts, R.A., Otto Weber, R. Lehmann, J. Whistler, &c. Mr. Alma Tadema is represented by a small cabinet picture of extreme beauty of execution, lent by Dr. Max Schlesinger. The subject, entitled "The Appeal," is conceived in a thoroughly classical spirit. A light-haired girl, in Italian drapery, is resting upon a long marble seat which extends the whole length of the picture. It is, apparently, the parapet of a bridge, for just above the coping a narrow streak of sea is apparent. In a recumbent position, lying full length on the seat by her side, is a dark youth, barefooted, who has put a question to the girl. The meditative mood of the maiden's face, her finger to lip, is exceedingly expressive; but the beauty of the composition, simple as it is, is the ideal sentiment and charming repose conveyed. The marble and the reflected light on the parapet and seat are alone worth inspection, no less than the quiet colouring and transparency. Guido Bach is so well known as an artist, that it will be unnecessary to say his sketches in water-colour are wonderful in their breadth and dexterous manipulation. We note a "Doorway at Plymouth," a sketch of an exceedingly good architectural feature, in which the colours are laid on with excellent effect; the cooler shadows upon the warm-toned surface of the stones are broadly managed, and the effect of roughness produced by some clever dragging of the dry brush. As an architectural sketch in colour this one will well repay the architect. The oil sketches by Mr. H. W. B. Davies, R.A., are freshly coloured; the smaller sketches, of which there are four, exhibit some of the higher excellences of landscape painting. We remark the delicate, yet broad, treatment of foliage and grass; the moonlight sketches are also exquisitely true and careful. Mr. Carl Haag sends a large water-colour three-quarter figure entitled "Eine Druidische Neize." The picturesque costume of the girl carrying a bunch of mistletoe in one hand and a sickle in the other, betokens her office; the face is sweetly expressive, and the gleam of light on the cheek and her golden hair are painted with extreme delicacy. Mr. Hubert Herkomer lends several portraits—all of them characteristic of that power and individuality for which he is noted. The portraits of his father and mother are life-like and vigorous; the modelling of features and texture of skin are masterly. We may particularly call attention to the portrait of "An Old Lady," and that of his child which exhibit in a marvellous manner the power and technical execution of the artist. These, and Mr. Edwin Long's series of studies of heads, painted in Cairo, Baalbec, Damascus, Granada, and Tangiers, of which there are twenty exhibited, form a collection of great interest to the admirer of portraiture and character, that cannot be surpassed. A picture in oil, of considerable feeling, mellow in tone, is Mr. G. Pope's "Daily Bread." It represents a widow artist seated in her studio, painting, a little girl behind her chair, with a picture-book in her hand. Mr. E. J. Poynter, R.A., exhibits four studies. The principal one is a cartoon for a picture in charcoal, representing "Perseus." Mr. Poynter has, apparently, taken the myth in which the son of Zeus arrives at the abode of the Gorgons. The composition is perhaps a little too much

broken up. The charcoal study for a picture is, in our opinion, more successful. Mr. G. F. Watts, R.A., sends a very impressive, though gloomy, picture of large size, called "Death," which certainly, whatever its merits, is rather repulsive to the feelings. In the gloom of night, under a massive arch, like that of Waterloo Bridge, which occupies the whole canvas, crouches a poor, forlorn woman, tightly wrapped in her scanty garments, nestling up to the arch, as if to procure warmth. We might mistake it for sleep, had not the painter given us the drawn and rigid features of death. The hushed quietness of night, the faint outline of a dome beneath the arch, and the reflected lights in the water are powerfully painted. Three studies of heads in red chalk, by Dante G. Rossetti, must be noticed for the poetical sentiment conveyed in the countenance, no less than for the execution. Near Mr. Britton Riviere, A.R.A., exhibits a chalk composition of forcible character, entitled "Acteon." Several smaller pictures call for attention. Mr. N. Chevalier's sketch of a mountain valley or glade is an extremely clever study of tinted foliage, the high lights being opaque upon a charming transparent ground. Mr. W. Kumpel's charcoal drawing, "Sport," is a study of much merit; here the forest of trees and the light and shade are vigorously drawn, and the same artist's "Beeches in the New Forest" are remarkably clever in the telling effect of broad washes of colour. We cannot omit to mention a composition drawing entitled "Spring," a festive procession in the New Forest, by R. Huttula; "In Tow," by Arthur Hopkins, a very clever sketch of water and boat ploughing the waves; and "The Highland Home," by W. Small; and H. F. Bluhm's "Modern Shylock," etchings by L. Lowenstam and J. Whistler, and some works by F. Walker, A.R.A., J. Wolf, and W. Bottomly. For powerful drawing and grouping, precision, and delicacy of technical qualities, the German school of artists, many of whose works are to be seen here, will well repay study.

COL. JAMES FAIRMAN'S PICTURES AND STUDIES.

AN exhibition of pictures and studies by the above gentleman is now open at 9, Conduit-street, the collection comprising chiefly views of some of the richest scenery in the United States. Col. Fairman is a painter of much power, and his pictures, if they do not equal some of those of our gifted landscape artists, have nevertheless qualities that will command attention. The finest is certainly his grand sea-piece, "The Power of the Sea," a study from the west coast of Ireland, which for grandeur of composition and breadth of handling is of considerable merit. A heavy sea is dashing over a rocky coast, the white surf of the waves being set off against a black thunder-charged sky. The painter has seized one of the grandest moods, and the rolling masses of water as they tumble over the sunken reef are painted with impressive force and liquidity. "The Indian's Adieu to his Native Valley, U.S.A." is a similarly large piece, with a touch of sentiment in it. The scene is supposed to be in Maine, a broad fertile valley, backed by mountains upon which sunshine and cloud have thrown an entrancing effect of light and shadow, and is being viewed by two solitary Indians. Rather fanciful, perhaps, it is intended to convey the reflections of the natives who have been driven from their beautiful country to the West by the Government. With good judgment, the artist has not intruded, by size or detail, his figures, which are, in this and other pictures, the least successful part of his work. We notice another picture, called "The Lake of the Great Spirit," suggested by the Indian legend that He appeared in the clouds of the sunset sky. It is a vast plain, lit up by a golden-red sky, the lurid clouds overhead assuming the form of an imagined deity. As a painter of architectural subjects, Colonel Fairman is less at home; yet "The Golden Gate, Jerusalem," is not without merit; the curved entablature of the gateway is carefully drawn. Another pleasing seascape is "Long Branch, near New York," showing the remains of a burnt vessel and some cleverly-painted sea. "The Plains of Sharon from the Mountains of Judaea" is a bright piece of sky, spoilt by the figures. We may notice the "Lake of the White Swan, U.S.A.," "A Mountain Torrent in the Highlands," as showing that

in water and mountainous or rocky scenery Mr. Fairman is *au fait*. A series of fine sketches in ink, chiefly American scenery in that most beautiful of the New England States, Maine, illustrate the artist's undoubted ability for landscape; and we notice one or two clever studies of rock and blue sea from the Massachusetts coasts, in one the stratification of the metamorphic rocks is peculiarly inclined, and appears to have been broken off. Those who are interested in scenery of this description will well be repaid by a visit to the Conduit-street Gallery. The pictures are all studies from Nature, and in the close rendering of some of her grandest aspects the artist has displayed both skill and technical knowledge.

ROTTEN ROADS.

MANY of our suburban roads are a real disgrace to a civilised community, and the cause in nine cases out of ten may be traced to an unsatisfactory adjustment of the parochial boundaries, or to an imperfect system of supervision. It is scarcely necessary for us to mention instances of bad and uncared-for roadways in the metropolis; they are found by hundreds in the outskirts of small residential localities, and though repeatedly brought before the public authorities by letters in the local papers, are destined to remain so. But it is of little use to complain so long as we see miles of roadway formed upon undrained ground, the inequalities of which are made up of rubbish heaps. In South London, no less than in the outskirts of the metropolis on the north-east, we may examine several roads which have been made up of "scavengers' material," utterly unsuited to form road foundations, repugnant to our sense of propriety, and certainly a source of danger to health. In what way such refuse can be deposited for this purpose it may not be difficult to discover; perhaps there is a contract with the scavenger of the district to deposit his rubbish at a certain place; however this may be, we have a right to be informed by whose authority such roads are constructed. In spreading road materials there is also, from want, of supervision a great deal of waste; the layers are not put on regularly, while the rotten substratum forms a soft, squeezable substance that soon produces holes and ruts. Some useful suggestions on this matter are given in Mr. T. Codrington's recently-published treatise on the "Maintenance of Macadamised Roads," lately noticed by us. Speaking of this, he says:—"A cubic yard of stones broken to a 2in.-gauge will cover about 30 square yards, so that 60 cubic yards would only coat about a quarter of a mile four yards wide. In this case each part of the road would be coated once in four years, and it must have sufficient strength to stand the wear of four years." Now in many roads the irregular wear is quite ignored, and we see every now and then a coating of new gravel placed alike on the unworn as well as the worn parts. The effect of this treatment must be obviously to waste material and to add thickness to places thick enough to bear traffic. Materials should only be laid on the parts that require them, and the object should be to bring the road to a uniform thickness throughout. Another weak point in the system of road-repairing or laying is that the hands employed to spread the material are not the most skilled in detecting the weak points of the road or in preserving the cross section of it. We have noticed many roadways upon which the most careless spreading takes place. But one of the principal points to observe in repairing is to apply the fresh material in the least wasteful manner upon those depressions or "slacks" of the road which require it. As in all good workmanship, there is an art here. The common method is to make the patches of new gravel square, by which a large part of the material is wasted at the corners. The worn hollows are invariably rounded or oval, sometimes irregular, and the art is to fill these hollows to their exact size and shape, and these patches will be found to be rather long and spindle-shaped, the ends being tapered to a point or very nearly so. Unless this precaution be attended to there are spots where the water will lie, and the patching in time produces unevenness and rotten roadways. Referring to the kind of material that produces the most economical result, we may observe that the French engineers have assigned certain values to different materials, and these are called "co-efficients of quality," but they have little

practical value, inasmuch as actual wear or traffic must be considered under particular circumstances. The harder limestones have advantages: they bind easily, the detritus mixed with the lime forming a kind of mortar which unites the materials. Chalk flints and gravel make good roads, and in the southern districts these materials are largely employed. Hard quartzose grits are recommended; and the idea of combining the coarser with the fine or cementing ingredients seems to be the correct one. A certain quantity of clayey gravel or chalk is necessary to make a coarse pebbly gravel bind well, and these materials may be sometimes added with good effect.

CAMPANILES AT SOUTH KENSINGTON.*

IN the architecture of other countries there are many features which at first sight do not commend themselves to the English taste. Among these are the campaniles of the North of Italy. With the form of the Leaning Tower at Pisa every educated Englishman has been familiar since his childhood; but he has been brought up to admire it rather as a curiosity than on account of any merits in its design or workmanship. Giotto's tower at Florence he considers a "pretty thing," though he has misgivings as to its architectural "correctness;" and he is usually pleased with the bell tower of the Palazzo Vecchio, in the same city. But there is a type of campanile very common in Northern Italy which few Britons admire until told that it is the proper thing so to do; we refer to the plain-sided, square-based towers, surmounted by open belfries, capped by short spires. A very eminent authority on architecture, Mr. Fergusson, in his *Handbook*, expresses what we venture to think was in pre-Ruskinite days the opinion of our best architects on the subject. He tells us that "throughout the whole of the middle ages the Italians retained the original square form" of tower, "making them as broad at the summit as at the base." And he goes on to say, "with very few exceptions they are without buttresses, or any projection at the angles to give them even an appearance of strength." That they have been strong enough to retain their positions since the middle ages does not seem to have satisfied the great architect. The consequence of their apparent want of support he considered to be that when a spire was placed "on such an edifice as this, it always fitted awkwardly"; and he finds fault with the medieval Italians because "they never understood the art of preparing for the spire," "first by the graduated buttresses of the base, then by the strongly-marked vertical lines of the upper part of the tower, and, above all, by the circle of little spirelets round the base of the central spire that made it an absolute necessity of the composition." Mr. Ruskin was, we believe, one of the first of our fellow-countrymen to go into raptures over these structures; having canonised Turner, he proceeded to beatify campaniles. Without committing ourselves entirely to his opinions on the subject, we agree with him that there is much to be said in support of the beauties of these North Italian bell-towers, despite their non-accordance with English views of belfry-building. Mr. Ruskin describes the campanile of St. Mark's at Venice, which is a good specimen of the style, as owing "none of its effect to ornament," as being built "as simply as it well can be to answer its purpose," with "no buttresses, no external features whatever," "one bold square mass of brickwork." He further describes it as having "double walls, with an ascending inclined plane between them, with apertures as small as possible, and these only in necessary places, giving just the right light required for ascending the stair or slope, not a ray more; and the weight of the whole relieved only by the double pilasters on the sides, sustaining small arches on the top of the mass, &c." A few lines later he adds, "Then, when the necessary height is reached, the belfry is left open, as in the ordinary Romanesque campanile, only the shafts more slender, but severe and simple, and the whole crowned by as much spire as the tower would carry, to render it more serviceable as a landmark." This arrangement, he observes, "is repeated in numberless campaniles in Italy." He then proceeds to compare the aforesaid tower

to one of the usual English type, very much to the advantage of the latter. Indeed his opinion of our native spires or bell-towers is so low that he goes the length of saying that "the four or eight pinnacled things we call towers in England (as in York Minster) are mere confectioner's Gothic, and not worth classing." We have no wish to enter into the merits or demerits of any bell-towers, and our only object in making the above quotations has been to show that Mr. Ruskin is the great prophet in this country of North Italian campaniles, and that we might naturally expect these who introduce them into England to be his disciples. But we shall refer to this presently.

Within the last few years there have been a few attempts at erecting Italian campaniles in this country, but they have not generally been on a large scale. The plainness of their arrangement has probably made some church-builders adopt it for economy sake, and they have, as the modern builder's phrase puts it, "run up" campaniles which are libels on Italian architecture. At last there appeared to be some promise of a satisfactory specimen of the style in our metropolis. Overshadowing one of the most deserted and little cared-for spots in London—need we say that we refer to the Horticultural Gardens?—two square-based masses of building suddenly sprouted from the ground, and out-topped the long line of the unfinished museum. At first even the Ruskinite was puzzled by these twin apparitions; but as they rose higher he fancied he recognised a likeness in them to the bases of his favourite towers, and as they advanced the similarity became more and more marked. It was not, however, until the open work at the tops began to shew itself that he permitted himself to indulge the hope that they were to be as children say, "really and truly" campaniles. Even then he was perplexed. What could they be for? Dismissing the idea that, like the gardens and conservatories beneath, they were to be allowed to become ruins, and like them, were intended to be exhibited to strangers at a shilling a head, after the manner of other ruins, he clung to the hope that they were perhaps destined to summon the neighbouring devotees to the High church and the Low church of the district, a chime of bells in a different key being hung in either tower to distinguish the one from the other. Only two other possible explanations remained—one that bell-ringing contests were to be included among the artistic accomplishments at South Kensington, the other that one belfry was to announce to visitors at the Museum the approach of trains bound for the Mansion House, and its neighbour that of those bound for Bishopsgate-street. But, like all other great works at South Kensington, the towers advanced more rapidly than the thoughts of deliberate thinkers, and before any definite conclusions as to their probable use had been arrived at by the *dilettanti* of Queen's-gate, the campaniles were finished. Their last stones showed a striking peculiarity. Instead of the spires being brought to comparatively sharp points, they were very blunt and curious in shape. As we looked at them, we remembered that the figure of an angel stood upon the spire of the campanile which occurred first to our memories; so we immediately concluded that these broad apexes were intended to support colossal bronzes which should excel even the Albert Memorial in their magnificence. We looked daily for the appearance of the angels, and at last saw something very different at the top of one of the towers. We hesitate to describe what met our eyes; but truth compels us to say that, instead of an angel, we saw a volume of thick and black smoke issuing from the summit of the spire, in a manner which reminded us far more of Birmingham than of Venice, and of the Inferno than of the abode of angels. Rejecting the dreadful thought which at once occurred to us, we endeavoured to persuade ourselves that the campanile was on fire, and were horror-stricken at the thought of the large amount of public money which might thereby be wasted. When, however, after patient watching, the campanile continued to eject dirty smoke in a very professional and chimney-like manner, we became reassured as to the safety of the structure, although we do not know that we were less uneasy about the waste of public money; and when the horrible truth flashed upon us, we should almost have been glad to have seen the building burnt to the ground.

We showed just now that Mr. Ruskin is the

great apostle of Italian campaniles, and that he is the chief authority on their merits. Let us, therefore, test these smacking campaniles at South Kensington by his standard. Writing of the virtues of architecture, he says:—"We have thus, altogether, three great branches of architectural virtue; and we require of any building:—1. That it act well, and do the things it was intended to do in the best way. 2. That it speak well, and say the things it was intended to say in the best words. 3. That it look well, and please us by its presence, whatever it has to do or say." Now with regard to the first of these three rules we have no complaint to make; the chimney evidently draws well enough—too well if anything; but as to the second, we can only say that the tower spoke as plainly as tower could speak, and said it was going to be a belfry and a belfry only, and that it afterwards turned out that in so saying it told what is termed, in schoolboy parlance, "the biggest lie" ever told by tower. Possibly its builders might defend it by saying that it was intended to tell a lie, and that therefore it did "say the things it was intended to say in the best words." How the disciples of Mr. Ruskin can reconcile all this with the "Lamp of Truth," of which he makes such a point in his *Seven Lamps of Architecture*, we are unable to say. As to the third rule, "that it looks well, and pleases us by its presence, whatever it has to do or say," we deny that a thing which is such a gross violation of every sense of art, beauty, or association—we had almost added decency—can possibly look well, or please by its presence, "whatever it has to do or say." The great high priest of campaniles particularly directs his followers not to mix ornament with business, and warns them against using golden ploughshares or binding ledgers in enamel; he tells them not to thrash with sculptured flails, nor to put bas-reliefs on millstones; and here we find them concealing an engine-chimney with the decorations of an Italian bell-tower. After this we do not think that the house-agents at Queen's Gate are likely to let a house to the critic who wrote many pages in praise of the lamp of truth in architecture, and called England "a machine and devil-driven country." The same writer laments that "there is not a tradesman's sign, nor shelf, nor counter in all the streets of all our cities, which has not upon it ornaments which were invented to adorn temples and beautify kings' palaces"; that there is not "the smallest advantage in them where they are," being there "absolutely valueless, utterly without the power of giving pleasure," only satiating the eye and vulgarising their own forms. He admits that "many of these are in themselves thoroughly good copies of fine things"; adding sadly, "which things we shall never, in consequence, enjoy any more." "Shall we ever enjoy campaniles any more?" is a question which those who happen to have windows looking upon the smoking tower under notice may not unnaturally ask themselves. Here is a fine form vulgarised, a form of ornament invented to adorn a temple, absolutely valueless and utterly without the power of giving pleasure. Why, in the name of art, of science, and of common sense a chimney could not be built like a chimney we have yet to learn; nor are we at all certain that a well-built factory chimney is much less graceful in its way than a campanile. It may be replied that its associations spoil it. Why, then, spoil campaniles by giving them the same associations? It is possible, indeed, that South Kensington might indignantly repudiate the authority of Mr. Ruskin, and even declare war against his principles. If this be the case, we congratulate South Kensington on the refinement of its cruelty. To take its enemy's favourite child, and expose it to shame before the eyes of fashionable London, would be a bitter revenge indeed. Perhaps the duties of inflicting torture, which were formerly allotted to the officials at the Tower, are transferred to the authorities at South Kensington.

If the hint thus given by the highest art officials in the kingdom is acted upon by our manufacturing fellow-countrymen, we may expect in a few years, whenever we travel through the Birmingham or Manchester districts, to see volumes of black smoke emerging from models of the dome of St. Paul's cathedral or even St. Peter's, of Giotto's tower, of the spire of Strasburg Cathedral, of the Great Pyramid, of Cleopatra's Needle, and even of those "paltry pinnacled things" the towers of York Minster and Westminster Abbey. Who knows that it

* From the *Saturday Review*.

may not become the fashion to make domestic chimneys also in the form of "good copies of fine things, which things we shall never, in consequence, enjoy any more!" We may live to see the roofs of our houses covered with "tall-boys" made after the pattern of the pinnacles on the roof of Milan Cathedral, and chimney-pots in the form of Etruscan vases. South Kensington will then, we suppose, feel satisfied that it has made England a really artistic nation. In the mean time, during our wanderings at Florence, Venice, or Verona, we shall be haunted by the dreadful thought that, in looking upon the campaniles of the past, we see the factory chimneys of the future.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

AN ordinary meeting of the Institute was held on Monday evening, the President, Mr. Charles Barry, in the chair. The following gentlemen were elected to membership:—As Fellow—William Henry Clark, Leon Chambers, Bristol. As Associates—Spencer William Grant, 14, Duke-street, Adelphi, W.C.; Walter Wheeler, 25, Boscobel-gardens, St. John's Wood, N.W.; Robert Clamp, 20, Seale-lane, Hull; and Isaac Steane, 22, Little Park-street, Coventry. As Honorary Associates—Sir Francis Philip Cunliffe-Owen, K.C.M.G., C.B., Director of the South Kensington Museum, The Residences, South Kensington, S.W.; Henry Stacey Marks, R.A., 15, Hamilton-terrace, N.W.; Edward John Poynter, R.A., 28, Albert-gate, S.W.; and the Rt. Hon. Richard Assheton Cross, M.P., Secretary of State for the Home Department, 53, Eccleston-square, S.W.

The SECRETARY (Mr. White) read a letter from the Metropolitan Board of Works, stating that the board will have great pleasure in complying with the request of the Institute for copies of plans, and forwarding four series of plans: those relating to the proposed Tower Bridge, to building sites offered by the board to be let by tender, to the improvement schemes proposed under the Artisans' Dwellings Act, 1875, and a plan of the metropolis showing the properties condemned under the recent Streets Improvements Act. The Commissioners of Sewers for the City of London had also promised to forward plans of the two schemes about to be carried out under the Artisans' Dwelling Act.

Mr. VULLIAMY, architect to the Metropolitan Board of Works, said instructions had been given him by the board to forward to the Institute all plans of improvements and of vacant land available for letting.

IMPROVEMENTS IN GLASGOW, AND THE CITY IMPROVEMENT ACTS: ORIGIN OF THE ARTISANS' DWELLINGS ACT.

Sir JAMES WATSON, hon. associate, read a paper bearing the above title, and exhibited a series of maps, plans, models, and photographs, illustrating the condition of Glasgow before the passing of the Glasgow Improvement Act, 1866, and at the present time.

It will be generally admitted, he remarked, that if we would seek to elevate the great mass of our industrial population in our large cities throughout the kingdom, we must endeavour to provide them with comfortable dwellings. If the home of the working man be cheerless, dark and unwholesome, the result will naturally be to drive him to the use of intoxicating liquors and too often to the public-house. A strong feeling of this has long existed in Scotland, and with the view of furthering it, movements have been made both in Edinburgh and Glasgow, especially so in the latter, and the movements, although somewhat retarded by the too often injudicious conduct of the workmen themselves, with their strikes and trades unions, have been attended with beneficial results. Every stranger who visits Scotland must be struck with the difference existing between the dwellings of the humbler classes in Scotland as compared with those in England. In England they generally reside in self-contained brick buildings, whereas in Scotland they almost entirely live in large stone tenements divided into separate flats, with more than one family on each flat. But a still more striking contrast consists in the fact that a large number reside in narrow lanes or closes in the older parts of the principal towns in Scotland, and although many of these lanes have been removed there are still a considerable number inhabited by this class of the population. The old style of

building was to erect large stone tenements fronting the street, with gardens behind, but as population increased large blocks of houses came to be built on the sites of these gardens, and stretching back as far as from 200 to 280 feet. Dividing these high tenements were narrow passages, or closes of from three to four feet wide. This system of building long prevailed throughout the large towns of Scotland. In a work published in 1736 giving a history of Glasgow, the author, Mr. McUre, after enumerating the eleven streets which then constituted the entire town, compares it to a comb with teeth on each side, the streets forming the centre or wood of the comb, and the teeth on each side representing the narrow lanes or closes. Maps published in 1776 and 1800 show that in the part of the city then built (and when the population amounted only to about forty thousand) this system then prevailed. One is tempted to inquire what could be the reason which induced parties, when ground was comparatively cheap, to resort to such a style of building. In all probability it was resorted to for protection during the troublous times which so long existed in Scotland when families lived in masses to guard themselves from the raids of hostile clans or the oppression of the feudal barons. The early history of Glasgow is interesting. Originally it was a bishopric founded by David I. in 1120, who built a magnificent cathedral and richly endowed it. Houses gradually clustered around it; a university was founded in 1450, when the population amounted to 1500. As population increased ground rose in value, and builders taking advantage of the old system, and being without any Building Act to prevent them, filled up almost every inch of available ground in the centre of the city. The houses in these closes and lanes were long occupied by respectable people, but gradually deteriorated, and particularly so from and after 1847, by an influx of population from the rural districts of Ireland, bring with them habits which, however innocuous among the bogs of Ireland, were quite unsuited to the densely crowded parts of a large city. This class took possession of the closes, and greatly increased the overcrowding. In some of these closes from 600 to 800 people came to be huddled together. In 1866, when the Improvement Act passed, the density of the population in some parts of the city amounted in some cases to 600, and in others to about 1,000 per acre. The houses in these closes were generally old, dark, and ill-ventilated, without sufficient breathing space, and without family accommodation, there being only one ash-pit, &c., to each close—sometimes even for two closes—and when fever or small-pox broke out the results were appalling. The moral effect produced was not less disastrous. Such was the state of Glasgow when the Corporation, instigated by Mr. Blackie, then Lord Provost of the city, and Mr. Carrick, the city architect, formed the design of applying to Parliament for power to purchase and pull down whole blocks of these buildings, to sweep away these narrow closes, to open streets through the most densely-populated portions of the city, and to see that in lieu of these old and wretched houses buildings should be erected and vacant spaces arranged for, so as suitably to provide for the growing wants of the city. Plans were made with the necessary books of reference for the streets to be reformed and buildings to be taken down, and to every house scheduled notices were given, and an Act of Parliament applied for. The area of overbuilt ground thus scheduled extended to 88 acres, being nearly the whole of the old town shown in the map of 1800. The plans showed the formation of forty-five new streets or enlarged thoroughfares. Powers were sought to expend £1,250,000 on the purchase of these, and to take down, rebuild, or sell in conformity with the plans of the new streets or enlarged thoroughfares. Powers were also sought to borrow money on security of the buildings, and to impose a tax on the rental of the city (to be paid by occupiers) of 6d. per £ for five years, and 3d. per £ for ten years. The Act passed almost without opposition in the Session of 1866. Immediately thereafter a committee was appointed, over which the author presided, for the following six years. A tax of 6d. per £ was imposed for the first year, and a bank credit for £45,000 was arranged for until the tax was collected and money borrowed on security of the trust. A judicious person (Mr. Lamb) was appointed to negotiate for the purchase of property

privately, and as most of the buildings were old and dilapidated, and the owners willing to dispose of them, the committee succeeded in securing a considerable amount of property at very moderate rates. By the end of the first year they found themselves in possession of property to the extent of £500,512, obtained at from 10 to 14 years' purchase for dwellings, and 18 to 20 years' purchase for shops. By this time loans began to come in freely at 4 per cent. The sixpenny tax, which had raised a great amount of dissatisfaction and grumbling, was reduced to fourpence for the second year, at which it continued for four years. The purchasing went on, and by the end of the second year a large amount of property had been secured. Such owners of property as were willing to deal at moderate prices had their property purchased, while those whose demands were exorbitant were left over. A rule was laid down that no great improvement should be begun in any place which would enhance the value of the adjacent property until the whole buildings required for such improvement were purchased, and the adherence to this rule has tended much to the success of the enterprise. For the first two years nothing farther was attempted than putting the dwellings into a fair state of repair, and opening up some of the long closes by the removal of a portion of the back buildings so as to secure sufficient breathing space, and playground for the children. The pressure of the 6d., and afterwards of the 4d. tax, without the necessary changes being seen, gave rise to a crusade against the committee. However, everything was explained, and the good sense of the public ultimately prevailed. The proceedings of the committee were narrowly watched by builders, and when they understood that large clearances were about to be made, and remembered how little had been done for years in the erection of workmen's houses, they immediately commenced operations. The rage for building workmen's houses went on from year to year, whole streets of new houses sprung up, until the supply exceeded the demand. The committee, at first fearing that sufficient house accommodation might not be found for the displaced population, purchased two large lots of building ground in the vicinity, costing, including sewerage and laying out of streets and squares, £80,661, to give off to builders for erecting workmen's houses at moderate rates. The plan succeeded and resulted in a profit of £15,000.

In about two years after the passing of the Act, commenced the demolition of some of the old and dilapidated buildings which had been purchased, such tenements as were dens of fever and disease, and haunts of the criminal classes, being taken down at once. This demolition process, however, required to be gradual, as it was necessary to prove to the sheriff before ejecting more than 500 persons of the labouring class that an equal amount of house accommodation suitable for such class existed or had been otherwise provided. In this, however, there was no difficulty, as the erection by private enterprise of the new went on much faster than the demolition of the old. The clearance thus effected by the committee, aided as it was by certain railway operations requiring similar treatment, had soon a marked effect on the health of the inhabitants, whereby the mortality, particularly of children, was considerably lessened. For the first four years the attention of the committee was chiefly occupied with the purchase of property and removals already alluded to. The rest of the property was put into a sufficient state of repair and let so as to secure a proper income. By 1870 the property secured amounted in value to £735,000, and the money expended to £764,063, and in 1871, £931,231. In 1871 the Act was extended five years, and in the same year the chief constable reports as follows:—"Through the operations of the City Improvement and the Union Railway, the city has been cleared of the foulest dens of profligacy and crime, and their occupants scattered among a population breathing a purer atmosphere, thereby affording facilities to the police for bringing the vicious to justice more easily and certainly, than when the whole formed a concentrated and combined colony of ruffianism." Fears were at one time entertained that the dispersion of the low class to other parts of the city might contaminate these places, but these fears were found to be groundless. On the contrary, the sanitary inspectors have repeatedly reported that the condition of the displaced population has been

improved, and that, although paying higher rates for better houses in other districts they are satisfied of the advantages of the change. About 1871 the improvements began to be carried out by the sale of the ground with its buildings in order to carry out the plans laid down by the city architect. Care was taken not to put much in the market at one time, and the price obtained exceeded expectations. In all cases the ground has been disposed of by public sale. The result of the committee's proceedings to the present time may be enumerated as follows:—

	Property Bought and Paid for.	Ground Sold.
In 1872 ..	985,159 ..	124,307 ..
„ 1873 ..	1,087,365 ..	180,762 ..
„ 1874 ..	1,241,353 ..	513,112 ..
„ 1875 ..	1,315,008 ..	565,136 ..
„ 1876 ..	1,431,593 ..	774,091 ..
„ 1877 ..	1,487,362 ..	883,634 ..
„ 1878 ..	1,538,971 ..	921,538 ..

The property has been all acquired by private negotiation with the exception of three jury trials. The result of the operations has been to reconstruct large portions of the city. Wide and handsome streets with spacious shops and dwellings have in many cases taken the place of narrow streets, and lanes of old and dilapidated buildings. Narrow closes from whence the criminal classes were wont to issue nightly in quest of prey are now all but unknown, and respectable dwellings and warehouse premises have taken their place. Fever dens have been removed, and the death rate which was on an average 29 per 1,000 in 1866, was reduced to 25 per 1,000 in 1876, a saving of life in a population of 500,000 equal to 2,000 annually. Last year the average was 26 per 1,000 notwithstanding the unusually severe weather during the last months of the year. There are still, however, portions of the city requiring reconstruction, which are being attended to by the Commissioners. Ground in the centre of the city was found to be too high in price to allow of the erection of workmen's houses. The buildings, therefore, which were erected there on the site of those pulled down, have consisted chiefly of shops and warehouses, along with dwellings for the middle classes. Those built for the working class have been erected at some distance from the centre of the city, where the sites were less costly. The following letter, received from Mr. White, the Assistant Master of Works, explains one of the plates exhibited at the meeting, and is an average specimen of the class of workmen's houses lately erected:—"Dear Sir,—I send herewith two tracings. Plate 8 is the plan of building erected by the Magistrates and Council in Warwick-street, which is 60ft. in width. It consists of four flats, each flat having two separate dwellings of two apartments and scullery. The arrangement is one of the best that exists; the apartments are large, the ceilings of good height—viz., 10ft., and the height of the building 45ft. 6in. The free space requisite is three-fourths of this height, actually it is much greater, as the plan shows. Plate 9 is the plan of building erected in Dalmarock-road, a street of 50ft. in width. The ground flat is occupied by two shops, each of which has at the back an apartment which may be used as a dwelling. The three upper flats have three separate family dwellings on each flat, two of them having two apartments, and the centre one one apartment. The single apartment I do not approve of, my opinion being that there should be no separate dwelling of only one apartment. The height of the building is 45ft., the ground flat having a height of 12ft., the others of 10ft. The free space necessary, in accordance with the Police Act, is three-fourths of the height. Notwithstanding the great care taken by the Court in examining plans to see that the arrangements for dwelling-houses are as complete as possible, in some instances it is rendered unavailing on account of houses, consisting of three and four or more apartments, and which when the plans passed the Court, were shown as and intended to be occupied as one dwelling, being converted into single apartments. If the proprietors were bound to make application to the Court, it would not allow such alterations without sufficient means of ventilation being provided."

By a clause in the Glasgow Police Act, obtained in 1866, no building in which there are sleeping apartments is permitted to be erected, unless there be a free space in front of the window equal to at least three-fourth of the height of the wall in which it is placed. In streets formed since the Act, the width of the street must be equal to the

height of the building. Where there are no sleeping-apartments, it is in the discretion of the Court to allow the building to be higher than the width of the street by one-fourth. In the old streets, however, formed previous to the passing of the Act, there is no such restriction as the width of the street regulating the height of the building. The consequence is, that large tenements, in which there are no sleeping-apartments, have been erected in several of our narrow streets, thereby excluding to a large extent the sunshine, air, and light of heaven. The restriction as to the free space in front and behind all buildings in which there are sleeping-apartments, amounts on an average to about 30ft. of open ground. As far as the space in front of the building is concerned, it is well adhered to; but as regards the space behind, the Act is frequently evaded by parties who are proprietors on both sides of a square erecting tenements with a space of 30ft. between the buildings in place of 60ft., which would be required if the buildings belonged to different parties. Thus the 30ft. is made to do double duty. This is felt to be particularly objectionable as regards hollow squares, where, as they are closed on all sides, there is a total want of air circulation. A very salutary regulation was introduced into the Police Act, requiring all apartments to be of such a size as to admit a certain amount of cubic feet of open space, as follows:—"If such dwelling-house consists of one apartment, and was used as a separate dwelling, previous to the passing of the Act, unless it contains at least 700 cubic feet of space, or, if it was not so used, unless it contains at least 900 cubic feet of space. If such dwelling consists of only two apartments, and was used as a separate dwelling previous to the passing of the Act, unless it contains at least 1,200 cubic feet of space, or, if it was not so used, unless it contains at least 1,500 cubic feet of space. If such dwelling consists of only three apartments, and was used as a separate dwelling previous to the passing of the Act, unless it contains at least 1,800 cubic feet of space, or, if it was not so used, unless it contains at least 2,000 cubic feet of space." This is exclusive of closets, presses and recesses not exceeding four feet in depth, and not having a separate window therein. By a subsequent clause powers are given to persons appointed by the Board of Police from time to time to enter any dwelling-house which consists of not more than three apartments, for the purpose of measuring, in cubic feet, the space contained therein, and to mark on or over the outside of the door of any such dwelling-house (if the cubic contents thereof do not exceed 2,000ft.), or to affix thereto a ticket on which are marked, in such position and style as the Board see fit, the number of such cubic feet, and the number of persons exceeding the age of eight years who, without a breach of the provision after mentioned, may sleep therein. This provision is, that when apartments are used for sleeping in by a greater number of persons than in the proportion of one person of the age of eight years or upwards for every 300ft. of space, or of one person of an age less than eight years for every 150 cubic feet of space contained therein, every person so using or offering to be used, shall be liable to a penalty not exceeding five shillings a day during which it is so used. The overcrowding which existed previous to the passing of this Act may be learned from the fact that, of 58,003 houses visited in 1866, the year the Act passed, no less than 4,948 were found overcrowded; and such at that time was the scarcity of workmen's houses, that the police were unable to carry out their regulations with effect. The number summoned that year was, therefore, only those of a very aggravated nature—viz., 953. In 1847, the Superintendent of Police reported in regard to the numbers living in lodging-houses of a low class, that were he strictly to enforce the Lodging-House Regulations, he would turn out 6,000 persons nightly to the streets. Since the Improvement Act came into operation, however, with the erection of whole streets of houses for the working classes, it will be seen by the following figures how greatly and gradually this overcrowding has decreased, although from the nature of the population it will always to a certain extent exist. In 1871, the number of cases brought before the police-court for overcrowding, after the magistrates began strictly to enforce the regulations, were, in 1871, 3,143; 1872, 1,741; 1873, 1,162; 1874, 1,540; 1875, 1,623; 1876, 1,446; 1877, 1,247; and in 1878, 1,141. Thus, in 1878, a year of great poverty and want of

employment, the cases were not much more than a third of what they were in 1871. The regulations contained in the Police Act in regard to free space and size of apartments, along with others for securing sufficient ventilation and drainage, have tended so far to the improved sanitary condition of the city; but in this respect they are still found inadequate to cure the evils under which we suffer. An application has consequently been made to the Home Secretary for a provisional order giving additional powers. "If the public health is to be considered, application should be made (our authorities think) to the Court, and consent obtained before houses of four, five, and six apartments can be reduced to houses of one or two apartments. The free space connected with buildings should be made what it was originally intended by the Act, and hollow squares should for the future be prevented. The cubic feet of space in the apartments of small houses should be enlarged, and all drains, soil pipes, and cesspools be constructed and ventilated to the satisfaction of the Dean of Guild Court and the Master of Works." This last is a matter of vital importance to the health of the community. The Dean of Guild Court, to which everything connected with the erection and superintendence of buildings and formation of streets is referred, consists of the Dean of Guild as President of the Guildry, or Merchantmen, along with three master-tradesmen sent by the Trades House, three merchants from the Merchants' House, the Master of Works for the City, the Fiscal or Public Prosecutor, and a legal Assessor. No building can be erected until the plans are submitted, examined and sanctioned by this Court; and all alterations affecting the exterior of any building must also, before being executed, pass this Court. A supervision is kept over all buildings in course of erection, and when buildings become dangerous they are required by the Court either to be rendered safe or taken down. The decision of the Court can only be appealed to the Court of Session; and such is the care taken in these decisions, that very few are ever appealed. This Court has proved of the greatest service to the community. It is evident that no lasting benefit can be derived from Improvement Acts, unless care be taken by sufficient building regulations to prevent the recurrence of such evils as these Acts are intended to remedy. In vain need we spend money to lessen the density of the population, if builders are to be allowed to place erections on every available inch of ground; and in vain do we seek to improve the health and comfort and morality of the people unless we secure for them a free circulation of light and air. We come now to inquire at what cost this has been effected. In a careful estimate made up by the author with the aid of Mr. Morrison, now the chairman of the committee, and Mr. Nicol, the city accountant, the whole cost of these improvements at 31st May, 1877, was found to amount to £178,462, arising from waste rents, interest of ground for a time unbuilt before being sold, parliamentary expenses, and expense of management. The result was made up as follows:—Ground sold and on hand as valued, £1,647,332, and ground sold and paid for, £1,612,501, showing a difference of £34,828. There have been taxes raised, £283,462, and taxes are to be raised at 2d. per pound, £80,000, making a total of £363,462. From this we must deduct price of a public park, £40,000; ground thrown into streets and open spaces, valued at £100,000, and paving streets and construction of sewers, £65,000, in all £205,000. There is thus a net loss of £158,462, which with £20,000 allowed for contingencies, makes the whole charge to the city, £178,462, as already stated.

The last point is the manner in which the displaced population has been provided for. It has been shown by the chairman, Mr. Morrison, that during the first ten years after passing the Act, say until the middle of the year 1877, the population displaced was 28,965; we must add natural increase of population requiring accommodation, say 9,000 annually for ten years, 90,000, a total of 118,965. To meet this there have been provided within the municipality accommodation for 202,302 persons, and outside the municipality, and within half-a-mile radius of the city, accommodation for at least 100,000, in all 302,302, so that the supply is in excess of the demand by 183,337 persons' accommodation. While this provided for all who were able to pay a moderate rent it entailed considerable hardship on a class belonging to a lower strata who lived

in small houses and rental at £2 10s. and £3 per annum. Accommodation has been found for these:—1st. By a number of tradesmen vacating their old and removing into the newly built houses; 2nd. By converting large dwellings in the older parts of the city into single and double apartments; 3rd. By the erection of model lodging houses, where parties unable to keep a house are provided with lodging, including fire, gas, and cooking utensils, at 3½d. per night, or 1s. 9d. per week; Sunday gratis. There are now five of these houses belonging to the Trust, and two more in course of erection. The cost of the whole is estimated at £80,000. They are all well frequented, and are self-supporting. The construction is peculiar and well adapted for the purpose. A shop or store is attached to each house, where the inmates can procure such articles as they require and cook them in the large cooking hall of the house. There are also cooking depôts throughout the city where good food is supplied at very low rates. The proceedings I have described attracted the notice of Mr. Cross, the Home Secretary, who requested information as to details. He afterwards visited the scene of these operations, and as the result brought in and passed the Artisans' Dwellings Bill, which promises, if taken advantage of, to be of great value to our large cities. It is deeply to be regretted, however, that so very few of them have as yet done so, although in many the reforms alluded to are loudly called for.

A discussion followed the reading of the paper, and was continued on Tuesday evening. We are compelled to hold over our report thereof till next week.

THE CARLIOL TOWER, NEWCASTLE.

MR. E. J. SMITH, the Crown Receiver for Northumberland, held an inquiry at Newcastle-on-Tyne on Saturday, on behalf of the Lords of the Treasury into the petition presented against the proposition of the Newcastle Town Council to remove the Carloli Tower in connection with the erection of the new free library. The Sheriff spoke in favour of the Corporation plan, and pointed out that all the alternative schemes had been fully considered by the committee before they decided upon the one they sought to carry out. The Commissioner asked if there was no further point as to how far it was absolutely indispensable that this tower should be extinguished, and as to whether it was possible to adopt a scheme for keeping the tower and still carrying out the objects of the Free Libraries Committee. Mr. T. Oliver said he had such a scheme, and put in a plan showing what he proposed. He said in his design he never contemplated removing the tower. He proposed going round about it, as he did in the case of the erection of the Mechanics' Institute, which he designed and carried out. In his opinion the tower should not be removed. It would cheapen the cost not to remove the tower. Mr. Fowler pointed out that Mr. Oliver's plan was not a correct one, and showed the discrepancies in it. Mr. Oliver said he knew the plan was not correct; it was only a rough sketch plan, but it was only a clerical error. He explained the mistake to the Commissioner when he put it in. The Commissioner said the dimensions could be easily altered; the building could be carried back a few feet. Mr. Fowler: The present Mechanics' Institute cannot be utilised with such advantage as it otherwise would be if you carried out Mr. Oliver's plan. The Commissioner: It is a question of degree on either side. Mr. Fowler then put in a plan showing the scheme recommended by the Corporation, and said he calculated that they would save from £5,500 to £6,000 if it were so carried out. Though it was not for him to say so, they should have also a very handsome building, which would be a great improvement to the town. Mr. Oliver remarked, in regard to his plan, that it was only a clerical error. He got the position of the tower, he might tell them, from one of the surveyors. Surveyors were not, he apprehended, more correct than architects. Mr. Fowler himself having made a mistake of some £10,000. Mr. W. H. D. Longstaffe next addressed the Commissioner, and commenced by reading a document from Mr. Johnson, architect, who submitted that if it were absolutely necessary to erect the Free Library on that site, it could be done so as to preserve the tower, and in a great measure the very valuable open space, by repeating, with

some modifications, the block plan of the Mechanics' Institute. Addressing the Commissioner, Mr. Longstaffe spoke of the line of the old wall round the town, and said its whole history was perplexing, and for this reason he did not want a single stone removed. He also contended that if the tower were pulled down it would offend several gentlemen who otherwise would make handsome presents to the Library. Mr. Gibson Kyle made some remarks in favour of retaining the tower, though had there been no tower he rather liked Mr. Fowler's plan. Mr. W. L. Newcombe, architect, said he spoke in support of Mr. Oliver's plan, first, as an owner of property in Higham-place; and, secondly, as an architect. The inquiry then terminated.

IRREGULARITIES IN INSTRUMENTS OF LINEAL MEASUREMENT.

IN a paper on "The Imperial Standard of Length for Free Public Use," recently read before the Institution of Engineers of Scotland by Mr. A. B. Allan, C.E., the author dwells at some length on the necessity of remembering and providing for probable inaccuracies caused by irregularities in instruments of lineal measurement.

Proceeding to the consideration of long instruments of lineal measurement, the chain may first receive attention. This instrument, whether 66ft. or 100ft. in length, is, from the nature of its construction, peculiarly apt to vary in extent. By the links becoming bent or the joints getting filled with dirt it possibly may be shortened, but either of these disturbances give rise to no very great error, and may readily be detected and removed. The real defects of the chain consist in its liability to elongation, and this arises from two distinct actions which cannot be ascertained by simple inspection, or conveniently set right by the engineering surveyor. These are the wearing of the surfaces which are in contact, and the opening of the joints. The wearing of the surfaces, never very great absolutely, may be relatively great or small, according to the weather during which the chain is used and the care taken in preventing rust. The opening of the joints, on the other hand, may lead to a serious stretching, and this is not to be wondered at when it is remembered that in a chain as usually made there are no less than 503 joints all capable of being opened, and which the using of the chain constantly tends to open. Of course, the extension due to such action increases with the continued use of the instrument, and the combined effect may be an error easily amounting to 5in. or 6in. on a length of 100ft. without the chain exhibiting any apparent symptoms of being out of order. While not prepared to propose a new construction of this instrument, Mr. Allan suggested that there is evident room for some improvement whereby it would be rendered much less extensible.

A course of careful observation leads to the distinguishing of three varieties of tape-lines depending upon the association of different degrees of stiffness, with ultimate strengths, which also vary. Thus there are (1) tape-lines which have small ultimate strength, with a certain amount of elasticity; (2) those which are strong and very elastic; and (3) those which are strong and stiff. The characteristics indicated under the first head are those possessed by inferior tape-lines of flimsy manufacture. The second variety, from its being of a stouter structure, is no doubt meant by the maker to be superior to the first, but is only so in point of durability, not of accuracy. The first loses its elasticity rapidly, and becomes permanently elongated to an extent eventually exceeding the range of elasticity. The second loses its elasticity less rapidly, and takes a set of elongation, increasing so gradually that the tape is most probably otherwise worn out before its elasticity is altogether exhausted. As regards accuracy of measurement both sorts are equally defective, because even with the most careful handling it is impossible to avoid error where there is excess of length or of elasticity in the measuring instrument. It is not uncommon to find a 50ft. tape-line, of the kind first referred to, too long to the extent of 1½ or 2in., after a short time's use. The range of elasticity of tape-lines of the second kind and same length is in some cases as much as 3in. Tape-lines of the third variety are practically inextensible, being stoutly made and devoid of elasticity.

Having thus classified these instruments according to their tendency to extension, it should next be mentioned that they are all liable to shrink on becoming wetted. The amount of this contraction depends on the condition of the surface of the tape-line and the length of time it may have been exposed to moisture. In a new tape, the surface being nearly waterproof, the shrinking is at first very little, but goes on augmenting as the surface becomes worn, until ultimately it may be as much as 2in. on a length of 50ft. However this shortening, although it may appear so at first sight, is in reality of little consequence provided it be observed and set right, as it readily may be by simply stretching the tape to its original length. But care should be taken that this is only done when the tape has been thoroughly dried. If this be attended to, there will be no tendency to shrink again until the tape is once more exposed to the influence of moisture. From the above considerations it becomes obvious that the requisites of a good tape-line are strength, stiffness, and a durable waterproof surface; and as there are no means whereby a tape-line, which is too long, may be brought back to lasting accuracy, it may be said of long instruments of lineal measurement, that contraction represents a temporary variation, whereas elongation is the result of permanent deterioration. Steel ribbon measuring lines, on account of the care necessary in manipulating them, can hardly be said to be in common use. They supply, however, a very reliable means of measurement, their only variations being those due to changes of temperature.

BRITISH ARCHÆOLOGICAL ASSOCIATION.

THE ninth meeting of the session was held on Wednesday last; Mr. Syer Cuming, F.S.A. (Scotland), in the chair. Mr. G. Wright, F.S.A., detailed the progress of the arrangements for holding the congress at Great Yarmouth, and read the programme of places to be visited. Mr. J. Brent, F.S.A., described a cup of Castor ware which had been recently found at the Pan Rock, Whitstable, a site which has hitherto yielded only Samian ware, affording evidence that this remarkable spot was a storing place for Roman pottery, and not a manufactory. He exhibited also several bronze celts from Canterbury, &c. In the discussion which followed with respect to the pre-historic character of some of the articles, the chairman referred to the numerous pre-historic relics found near London Wall. Mr. Myers, F.S.A., exhibited a large collection of terra-cotta objects, collected by him in Asia Minor and Africa, including a photograph of a remarkable aqueduct at Algiers of early Arabic date, recently destroyed to make way for gas works. He was followed by the Rev. M. Maynard, who produced an interesting series of very early articles from Cyprus, among which were some of Egyptian date and style. Mr. Loftus Brock, F.S.A., exhibited a fragment of Gothic tracery work in stone, blackened by smoke, probably the result of great fire of 1666. It was found in some recent excavations at London Wall.

The first paper was by the chairman, and had for its subject the seasonable one of "Easter eggs." After referring to the derivation of the name "Easter" from the Teuton goddess, who was represented with eggs on her head, he traced the uses of eggs by many early peoples and races. In Christian times the Copts suspended them from the roofs of their churches. They are found in terra-cotta in Etruscan tombs; in England they were supposed to preserve the owners from mischief; in early times there is abundance of evidence that they were worshipped by the Celts, and a remarkable custom still extant in Brittany was dwelt upon. Several examples of much interest were exhibited, one with the emblems of Astarte and of Christ, another of iron, of Russian origin, with representation of the Ascension; and a third, of Kentish origin, which had been decorated gaily in colours. The second paper was by Mr. C. W. Dymond, C.E., who described with great minuteness the present condition of the "Hurlers" in Cornwall, and the two other supporting circles, there being three in all. The paper was illustrated by an elaborate plan, which will appear in the "Journal," showing the position of all the stones which now exist and their relation to each other.

ILLUSTRATIONS.

DESIGNS FOR DECORATIONS, BY ALBERT DÜRER.—CARVINGS AT THE NEW PREMISES OF THE ART UNION OF LONDON.—SOUTH VILLA, REGENT'S PARK.—NEW BOARD SCHOOLS, HANOVER-STREET.—NORMAN TOWER, BURY ST. EDMUND'S.

OUR LITHOGRAPHIC ILLUSTRATIONS.

DECORATIVE DESIGNS BY ALBERT DÜRER.

CONTINUING our series from the drawings by the old masters, we publish to-day a reproduction from one of Albert Dürer's own drawings, illustrating some characteristic and spirited designs for decoration in the style of L. Della Robbia. The swag is suggestive, and the cherubs are full of good drawing and vigour. The want of perspective and uncertain way in which the architectural details are shown is quaint, but unworthy of Dürer. The original drawing was slightly tinted with flesh washes and tints of blue and pink to the drapery. The drawing was exhibited this year at the Royal Academy Exhibition of Old Masters, and belongs to Mr. Edward J. Poynter, R.A., who has kindly placed the drawing at our disposal for publication. Dürer's monogram is not given as here shown on the original.

CARVINGS FROM THE ART UNION FOR LONDON NEW PREMISES, STRAND.

A fortnight since we gave the upper and lower portions of the panels between the first or principal floor windows of this new building, and to-day, in obedience to our promise then made, we publish the central portions of three out of the set of four panels. We refer our readers to the remarks already given when the other details and general drawings were published in our pages. Messrs. Mabey, of Westminster, executed the carvings; and Professor E. M. Barry, R.A., is the architect of the building.

SOUTH VILLA, INNER CIRCLE, REGENT'S PARK.

THE Crown lease of South Villa was purchased by Mr. T. J. Waller several months ago. The former house was a work in the Doric style, by Mr. Decimus Burton, which had been added to at various times. After making some attempts in the direction of enlarging the premises, it was finally determined by Mr. Waller that nothing

short of rebuilding would suffice for his wants, and be worthy of the beautiful surroundings, and he instructed Mr. Gundry, architect, of the Adelphi, to prepare plans for the new house, which we illustrate by our double-page view with plan this week.

BOARD SCHOOLS, HANOVER-STREET, ISLINGTON.

One of the most picturesque schools which Mr. E. R. Robson, the architect to the London School Board, has built in London, is that which we illustrate this week. The building is situated in Hanover-street, Islington, and overlooks the canal, as will be seen by the view which we give. This is taken from the drawing which Mr. Robson exhibited last year at the Royal Academy. The style is characteristic of Mr. Robson's work, and the materials used are stock brick for the general walling, with red and cut brick dressings, and red tile roofs. The school provides accommodation for 264 boys, 264 girls, and 300 infants, making a total of 828 scholars.

THE NORMAN TOWER, BURY ST. EDMUND'S.

THIS fine example of Norman architecture formed originally one of the two principal entrances to the grounds of St. Edmund's Monastery; its erection was begun in 1117, and completed in 1130. The other gateway (now known as the Abbey gate), which was probably of similar character, was destroyed during the sacking of the Monastery by the townspeople in 1327, and rebuilt soon afterwards in later style. In the "Journal of the Archaeological Association," will be found a full description of the remains of this interesting Abbey, by Mr. Gordon M. Hills, and in the BUILDING NEWS of August 15th, 1869, a report of a paper on the same subject, read by Mr. Morant before the Royal Archaeological Institute when at Bury St. Edmunds. Our illustration is taken from a drawing by Mr. John W. Simpson, in last year's exhibition of the Royal Academy.

MR. WILLIAM MORRIS IN QUEEN SQUARE.

LAST week, the *World* sketched Mr. William Morris, the decorator and poet, at his studio in Queen's-square, in its gallery of Celebrities at Home. Mr. Morris is described as a middle-aged, thick-set man, broad and deep of chest, and with head curly as to hair and beard, decidedly handsome and barely silvered over. Turning from his easel to welcome the correspondent, Mr. Morris holds out a hand stained dark blue, protruding from the sleeve of a grey shooting-jacket under a wristband still more blue than itself. He explains "You see I dye all my patterns myself, and worked a long time at a dyer's in order to qualify myself practically for this important part of our work." Has he also mastered the art of staining glass? "No, we leave our glass work entirely to Mr. Burne-Jones. He knows so much more about it than anybody else; but I make not only designs, but actual drawings for upholstery, paper-hangings, and tile-work, and am very proud of my technical knowledge. It takes time, of course—but it is now sixteen years since we first began. As I have dyed at the vat, so I have passed months at the potteries, and flatter myself that I now know the capacity of my materials." Mr. Morris chats pleasantly as he works at the drawing on his easel. "You are speaking of imitators. We suffer far more from imitation than most people. Mr. Swinburne's imitators advertise him; our imitators take our property. They appropriate the schemes of decoration which are our real capital, and steal our very patterns. You are aware that in this country we can only register our designs for three years, after which they become public property. This time is too short. English people are slow to accept new ideas, and put off the evil day of submission as long as possible. Hence we find that, just as we have succeeded in introducing anything new it ceases to be our property. There is also the adaptor, who employs a vast deal of ingenuity in stealing the kernel of a design without the tell-tale husk which would bring him to grief. I wonder people are not ashamed—not of dishonesty, for that is common enough—but of their utter poverty of thought, the despicable sterility which compels them to follow the ideas of others in a slavish and tricky manner." Mr. Morris thinks that if art is to form a part of ordinary life in England the American system of patenting designs, so as to give the inventor a

fair chance of remuneration, must be adopted. At present he has to contend against abundant capital and technically clever designers, who are well paid for imitating his work. Amateurs and ladies are, however, in Mr. Morris's opinion, commercially harmless and only artistically a nuisance. Does he study from Nature and then adapt his work to the conventional forms he prefers for decorative purposes? During one period, he replies, he studied closely from Nature, but being endowed with a remarkably good memory for colour, form, and land-scape, he finds it unnecessary in a general way to proceed beyond its stores. For writing poetry or painting pictures he thinks the close study of Nature indispensable, but not so needful for decorative work. The son of a City man, but of Welsh descent, educated first at Marlborough School and then at Exeter College, Mr. Morris lit upon dull times at Oxford, and fell, like many of the young men of that day, into the ecclesiastical groove. It was the fashion just then for thoughtful undergraduates to fancy that they cared about architecture and decoration of the strictly Mediaeval pattern. The influence both of Rome and Ruskin told upon William Morris. After trying for the Newdigate and failing, he took a pass and drifted into Philistia. Before this he had prepared himself for active life by entering Mr. Street's office to study architecture as a profession. Following up this plan of life, he came to town, and devoted himself eagerly to architecture, decoration, and painting, and for five years published no line of poetry. His first volume had not been successful, and he worked at plans, pictures, and designs until he found, as he thought, his vocation in decorative art. To this he has been faithful for the last sixteen years, so far as the five working days of the week are concerned, Saturday and Sunday having been set aside for verse. Mr. Morris considers himself a fortunate and exceptionally happy man. His trade is not only profitable, but affords him infinite pleasure. His first little book, he candidly acknowledges, deserved to fail; all that he has written has brought him, he says with equal frankness, some accession of reputation, and he enjoys writing immensely—almost as much as he enjoys angling in the Thames by Leeclade.

EXHIBITION OF GAS APPARATUS AT LEEDS.

AN exhibition was opened on Monday in the Victoria Hall, organised by the Leeds Corporation, and intended to illustrate the various economic uses to which gas may be applied other than for the purposes of illumination. So large was the number of applications from intending exhibitors that only about three-fourths of them could be accepted. The selection, however, seems to have been carefully made, and as a result we have a display of gas apparatus by between thirty and forty of the principal manufacturers in England, including a large representation of local enterprise. The arrangements have been carried out under the authority of the Gas Committee, presided over by Ald. Bower, and the preparations, involving a large amount of anxiety and labour, have been made under the direction of Mr. Woodall, Gas Engineer. The real object of exhibitions like the present is of course, to equalise the consumption of gas throughout the year, by encouraging its more extensive use for cooking and manufacturing. At present the consumption of gas in Leeds during winter is at the rate of about 6 millions of cubic feet per day, whereas in summer only about 1½ millions of cubic feet are consumed, although the expense of maintaining plant and meeting charges for interest continue throughout the year with little variation. Cheap as gas is already in Leeds (only 2s. 6d. per thousand cubic feet, with a discount of 2½ per cent. for prompt payment), it might be sold still more cheaply if fuller use were made of the manufacturing plant during the summer months, as would be the case if the advantages of gas for cooking were more widely known. The display, which has been conveniently arranged in streets along the floor of the Victoria Hall, includes all kinds of ovens and stoves, burners, brackets, and gaseliers, boilers, grills, kitchen ranges, stew pans, bread toasters, &c., many of which are shown in operation. Some of the heavier articles, and the engines working with gas as a motive power, are shown in the crypt of the Town Hall.

THE SHEFFIELD SCHOOL OF ART.

THE conversazione of the Sheffield School of Art took place on Wednesday evening in the school in Arundel-street. The address to the students was delivered by Mr. George Edmund Street, R.A., who also distributed the prizes. The exhibition of paintings in oil and drawings in water-colours is this year entirely confined to the productions of students. The Science and Art Department sent down a valuable collection of European and Oriental pottery, metal work, and jewellery, bronzes, and electro-types, as well as drawings, etchings, and photographs.

Among the students' works were the designs submitted in competition for a prize of twenty guineas, offered by the Duke of Norfolk, for a casket to contain the Mayor's chain. The design of the prize-winner, Mr. Ernest Thickett, represents on the front panel The Last Judgment, while on smaller panels at the side are figures of Mercy and Justice. The lid is surmounted by two figures holding a shield for a coat of arms. The design is intended to be carried out in silver, with gilded panels. The Mayor's Prize of £10 10s., for anatomical studies, has been awarded to Mr. Austin Winterbottom, who was also successful in carrying the Master-Cutler's prize of £5 5s. for the best design for fish-knives and forks. The Atlas Works Prize of £5 5s., for the best Study from the Life, is won by Mr. F. W. Bramhall. A prize of similar value, from the same donors, for Study from the Antique, has been carried by Mr. John Lawson with a painting in sepia. Messrs. Martin, Hall, and Co. offered £10 10s. for the best design for a claret jug and two goblets. The prize has been awarded to Mr. Stuart Thorpe, whose drawing was purchased by the South Kensington authorities. Mr. Longden's prize (£2 10s.) for the best design for a carved wood picture-frame has been awarded to Mr. Charles Wilson. There were 13 competitors for the Montgomery medal for a drawing of flowers and foliage in outline or shading from Nature. The prize was awarded to Mr. John Fisher, who elected to make a panel instead of a drawing. Miss Annie Yeomans was successful in obtaining a National gold medal for a design for lace-pocket-handkerchiefs, cravat end, borders, &c., painted in Chinese white on a black ground. In addition to the gold medal, Miss Yeomans carries one of two "Princess of Wales Scholarships," awarded to the two lady students who take the highest prizes of the year in the national competition. In this class Mr. Stuart Thorpe also gets a medal for the design for claret-jug and goblet, already noticed. Another silver medal is awarded to Mr. Charles E. Wilson for a design for a ceiling, for which he also obtained the first prize of the Plasterers' Company in London. A bronze medal is also awarded to Mr. John Fisher for his model which carried the Montgomery medal. Twenty third-grade prizes have been awarded to Sheffield this session.

An interesting exhibit in the room is the album presented to the Prince of Wales. On the fly-leaf is printed "Paris Universal Exhibition, 1878. Drawings of the British Section, by Charles E. Wilson, School of Art, Sheffield." It contains 18 remarkably fine water-colour drawings, representing the Princess of Wales's boudoir, the Picture Gallery, the Canadian Trophy, and other views of the more important departments of the Exhibition.

Among the pictures by past students, the most prominent work in the room is a painting by Arthur Wilson, representing one of the grand apartments in the Louvre. Mr. Wilson also shows several other works, among them "the Entrance to Henry VII.'s Chapel, Westminster," a view of the interior of the same chapel, and a painting of a young lady. Mr. R. Hudson, jun., exhibits a river scene, with trees; Miss Habershon, who won the gold medal two years ago, has a domestic sketch; Mr. Reed-Turner exhibits a hunting-scene, representing hunters pursuing sport under the difficulties of one of Kingsley's North-easters: "Glen Massen" is a representation of Argyllshire scenery; "The Old Oaks, Sherwood Forest," lent by Mr. T. Firth; "The Don, Wharfedale Side," lent by Mr. C. H. Firth; and "The Old Bridge and Lock on the Don, at Tinsley," are by the same artist. Prominent among the water-colours is a group in still life, by Miss A. M. Dickinson, which has obtained a national medal; a portrait by Miss Ellen Gilmore; a group in still life by Miss Biram; and

some clever sketches of local men, by Mr. W. J. Stevenson. "Boreatton Hall," drawn by Godfrey Sykes, is from a design by Messrs. M. E. Hadfield and Son; Mr. W. Fisher, J.P., lends several more of Mr. Sykes' works. Mr. Stevenson shows a case of water-colours, with sketches of the reading-room at the Central Free Library, views of Sheffield, &c. W. Topham has several pen-and-ink sketches, also water-colours, illustrating old houses in and out of the town, one being a view of the old hall, Norton Lees. Miss Biram has a sketch of Whitby Abbey, and another of the old mill at Ambleside. W. H. Pigot has several sketches, including some of Haddon Hall and meadows, lent by Mr. Manuel. Amongst other contributors are Miss Habershon; Miss Wornall, whose rendering of cathedral architecture is effective; Miss Seaton, Mr. R. G. Smith, Mr. Arthur Wilson, and Mr. Read-Turner.

Among the other exhibits were some designs by Mr. Edwin Page Turner for tile decoration, and Mr. J. Brook. Mr. William Ellis exhibits marble busts of the Rev. S. Earnshaw and Mr. H. C. Sorby. Mr. R. W. Brookes also has several busts, one of them a medallion. Mr. Harry Hems, of the Ecclesiastical Art Works, Exeter, exhibits his oak coffer, which was shown at Paris and Philadelphia.

Mr. G. E. STREET, R.A., previous to distributing the prizes, delivered the following address:—Your committee, in asking me to distribute the prizes which have been awarded and to speak to you this evening on the subject of schools of art and their work, have given me a task which is specially difficult, I am sorry to say, in my case, owing to my very slight acquaintance with the ordinary work and routine of such institutions. I have, however, willingly responded to their request, for my sympathies have always been with them, and I have hoped and still hope that by their agency, if at all, we English people might be redeemed from a general apathy about art which characterises the mass of the people in all modern European countries in some degree, but most of all those who, like ourselves, boast most of their progress and their advanced civilisation. It is indeed a truth about which we cannot have any doubt whatever, that there is a certain kind of civilisation which, whilst it raises some men, tends to debase the majority to a very low level in all matters of taste, and in all natural artistic development and expression. The reasons for this do not seem to me to be far to seek. The perfection of machinery, for instance, enables an enormous number of men to earn their living by perfectly adapting themselves to one process to the complete exclusion from their thoughts of all others. And such a mode of work involves, consequently, a loss of intelligence which is hardly compensated by the perfection to which the machine—and the man, as part of the machine—succeeds in attaining. The consequence is that at the present day it is to the workmen of some half-civilised country that one has to turn if one wishes to find an example of correct taste in colour, or form, or in the adaptation of both to material; and that these precious gifts are either in part or altogether lost when the uncivilised workman comes too much in contact with the civilisation of the ordinary workmen and merchants of our own country. If you wish to find peasants dressing themselves in such a guise as to make the very sight of them a delight to the eye you must go to some far-off valley remote from railways and from curious travellers, and not to any of the towns or districts which science or manufactures have made their own. In former days the surprising skill which we still see exercised by the makers of stuffs and carpets in those countries or by the fitters and enamellers in Japan, was evidenced just as completely in every work which proceeded from the hands of our own countrymen. And what is so remarkable is that nothing that they did was ever absolutely vulgar, hideous, or commonplace, or false in its mode of dealing with material or in its suitability for its purpose, and that, in short, they reached the same high common and universal standard of excellence that we now see reached by only a few nations throughout the whole habitable globe. The attempt to correct such a state of things as that which we have to deplore, follows naturally on the discovery or realisation of its existence, and though some of their supporters find the use of Schools of Art to be merely the raising of our people to the same power of drawing as some other nation—as e.g., the French—may have at-

tained, I venture to think that the real reason for their existence, and the real claim that they have on men who hold right views, are that they may tend, if rightly directed, so to open the eyes of the many to the perception of what is good and bad in art, as to bring us back in time to something like that universal sense of the true and the beautiful, which is not impossible, because, as we know, the people of this country, from the eleventh to the sixteenth century, undoubtedly possessed it. Of course there are many things which must be made, and which are nevertheless wholly outside our province. A plate for an armoured man-of-war, or so complicated a piece of admirable workmanship as a marine steam engine, does not admit of any kind of decoration; and a vast number of things may come under the same category. Broadly speaking, however, whatever is to be in frequent use and constantly before the eye may be an artistic work, and ought—if it is ornamented at all—to be ornamented well; and though there is no reason for stamping the plates for a boiler or for an armoured ship with good patterns, there is no reason whatever why the door of a safe, the front of a fire-grate, or the crane which raises goods to the top of the warehouse should not be all the subjects of careful thought and design—not to mention the whole of the furniture and domestic utensils in common use in every one of our houses. In this town you have, owing, as I am informed, to the zeal of your Corporation, a means of seeing how in former days almost all men's work was more or less excellent in its character and workmanship. The Weston Park Museum is one of which you may well be proud, and it contains so many examples of work executed in materials which are the staple of your own manufacture that I cannot sufficiently praise the zeal and liberality which have provided them for the improvement of the general knowledge and taste of your people. There you will be able to see how good and well designed a knife and its handle may be—how exquisitely the old German work was hammered in iron, and even the nails of a door were works of art; whilst candlesticks, plates, vases, and cups, chased, stamped, and wrought in charming fashion, were all to be studied there. Or if you wish for something still more refined, you have in the Bateman collection some beautiful examples of the delicate works of the early Irish artists, some of which have seldom been excelled in after ages. And if you want to know how even a thing which was never intended to be seen or exhibited was nevertheless made worth seeing, I commend to your notice the interesting lead coffin in the lower gallery. I augur great results from the constant opportunity of study afforded by this museum, aided as it is by such loan collections as that which you have here now from the South Kensington museum. I desire, in what I say this evening, to devote myself as much as possible to pointing out to you students what I, an older student, believe to be the right way of using the opportunities which such museums and schools of art afford you for cultivating your artistic intelligence. When you begin to study art, unless nature has been exceptionally bountiful, as she is only now and then to young students, it is necessary that everyone should accept a great deal upon the authority of the teacher. At first sight the difference between such sublime work as the sculptures of the Parthenon and the commonplace or affected sculpture of the later Romans may not be perceived. But if the student has been made to draw frequently and carefully from the former, it will almost always be found that he will be less disposed than ever to trouble himself about the latter; and the mere habit of drawing well and carefully from the life or from the purest antique sculpture gives a natural sense of the beauty of lines and curves such as cannot be obtained in any other way with equal certainty. And there is this great advantage in such work that as no line is a repetition of any other, and as no figure seen in the world can ever repeat its lines in any part, the hand and the eye are both being trained at the same time to the most perfect appreciation of form and line—entirely without that mathematical accuracy which produces monotony, and is the most certain evidence of poverty of invention, and want of artistic feeling that I know. The study of the human form is then for the draughtsman the most important study to which he can devote himself. Among other advantages, it will lead him certainly if

insensibly to indifference for some qualities which at the present day have great and the most noxious influence throughout this country. Many of you may think that accuracy of workmanship, exactitude to the minutest point of colour, line, and texture are indispensable in a good article. It is pardonable if you do think so, for the belief is well-nigh universal. But I venture very confidently to tell you that there are varieties within the best works as much as of the very worst, and that just as God makes every man and every animal unlike his brother or the rest of his kind, so the variety which is absolutely incompatible with exact accuracy of execution is really the highest quality which any of man's works can have. You must, therefore, train yourselves to believe that one of the main reasons for insisting on drawing from the life in these schools is that you may learn to depend upon your hand and your eye for everything that you draw and design; the more you do this the more certainly will your work have some good and precious qualities. There is nothing that had done so much harm, and is doing so much harm, to the art of design, as the too frequent dependence on mathematical drawing instruments. If a man wants to design an ornament he brings all his dividers and his bow-pencil. He divides out his ornament with an accuracy which aggravates us, and never trusts to his hand to draw a curve whilst he can get his bow-pencil to do one for him. The result is that his lines and his divisions being all perfect, the design has a tameness and insipidity which deprive it of all the interest which nature's irregular works invariably have. And here I must caution you against accepting as true the attempts which are ever and again made to prove that the best Greek ornament was entirely an affair of the bow-pencil. If you draw admirable curves with your hand it may often be found possible to find a succession of centres which will enable you to draw the whole curve with an instrument; but this is quite a different thing from the attempt to devise the curve with instruments instead of with the hand in the first place. Remember Giotto's round O, and the moral which the story teaches. The greatest artist could draw a complete circle without the aid of an instrument, and this perfect power is what you must first of all possess if your hand is ever to do its duty as the obedient servant of the intellect. I could give you any number of examples in illustration of what I have been saying. But these are hardly necessary, and I must ask you to take my word on this point. The extent to which this practice applies is endless. There is a very common mode of designing ornament to which young students are especially prone. They are too often in the habit of designing a portion of an ornament, and then, by the aid of tracing paper, reversing and repeating the lines already drawn. In this way an eighth of a circle is made to do service for the whole by a repetition which irritates in place of pleasing. Compare it with a good piece of Medieval workmanship, or of modern Eastern workmanship, and you will find that the virtue of the latter is that the hand has drawn the whole, and that no part is a mere repetition of another. In the one the attempt has been made to make a little labour go as far as possible. In the other the work has been a pleasure to the man who has done it, and his happiness in his work reacts on the man who looks at it in exact proportion to its evident reality. No doubt you have had before your eyes from time to time examples of old Venetian glass, and I am led to refer to it now as affording an admirable example of the way in which artistic work depends upon the education of the workmen. You all know that the aims of the Venetian glass-maker and of the English workman are entirely distinct. The latter conceives that absolute uniformity is the one condition of perfect work, whilst the former never troubled himself to obtain anything of the sort. The old Venetian glass has therefore always excited the greatest admiration, and collectors vie with each other in their eagerness to obtain specimens of it. In spite of this, modern fashions so far prevailed that even in Venice and Murano the old practice died out, and it was owing almost entirely to the exertions of a man of our own time—Dr. Salvati—that the old mode of working has been recovered. He set himself to make his workmen think for themselves, and the result is that I never visited any manufactory with a tithe of the pleasure with which I visited his works at Murano. For

there I saw a number of workmen making, often out of their own heads, and always without any guide or model before them, the most exquisite glasses, vases, bottles, and vessels of all sorts—no two of them alike—all probably deficient in accuracy of dimensions and shape, but all of them done with a life and spirit which can be secured in no other way. What Dr. Salvati has been able to accomplish at Murano we ought to set ourselves to accomplish here. He has converted his workmen into thinking beings, has endowed them with a new perception of the beautiful, and has shown that it is still possible to revive in the most real way those dormant powers which we are too apt to suppose to be impossible of revival. Something of the same sort of credit is due to potters who like Mr. Deulton have devoted themselves to the revival of the half extinct art of the potter, whose work when well and tastefully thrown from a wheel is always valuable and interesting. There are rough earthen pots in your museum which have become interesting owing to the varied handiwork of the workmen. The indifference to exactness which marks such works as these is equally admirable when good smith's work is to be done; for here if the work is wrought with a hammer it is really better in every way than the marks of the tool should be perceivable than that the work should have the dull neatness of cast work. This you can see for yourselves if you study and draw the German iron work—in your museum—which you owe to the munificence of Alderman Bragge. Let me now detain you for a brief space only on another equally important subject, that of colour. Here you may indeed obtain from your masters some general information, but to achieve success, you cannot depend on rules, and must again depend upon an eye cultivated by careful and constant study of good examples. It is true, however, that in this matter you must have a natural instinct or taste for what is good. No rules and no amount of study will suffice to make some men good colourists. In my judgment the greatest want of our day is a due sense of the value of breadth and tone in colour. Mere contrasts of one colour with another are never so satisfactory as the combining colours in such a way as to produce delightful general impressions of tone on the eye. Nature here is the best mistress. There are times when the landscape and foliage are full of the most delightful suggestions, and at all times it is a safe rule to observe the way in which colours are combined and gradated in natural objects—such as flowers and the foliage—if you desire to know how to produce the best effects. And let me add that in colour and texture, just as well as in outline, evenness and accuracy are not virtues. Look at a piece of really fine old stained glass, and you will see that no pains have been taken to secure evenness of tint in the white or ruby or green or blue of which it is made up. Look at a really good majolica tile, or at a good Eastern carpet or stuff, and you will always find the same rule observed. I shall now give you a few words of advice on the mode of study which you must adopt when you leave these schools, and have to work or study by yourselves. Your main object must be, as I have shown, to make yourselves masters of that art of stamping your own individuality upon your work which has always been the mark of good workmen. This can, I believe, only be accomplished by cultivating not only your hand, but by pursuing your studies till you have worked yourself into a state of enthusiasm about them. In all good artists there is something of the spirit of the fanatic. To them their own work is the first thing in importance and their own mode of doing it the one thing to be concerned about. Many-sided men are prodigies, and not often to be met with; and unusually it is better not to aim at too many accomplishments, but rather to devote yourself to the perfecting of one thing at a time at any rate. In our great towns the conditions of life, our surroundings, our dress, the very atmosphere itself, are all distasteful and distressing to the artistic eye. But all of you can occasionally, I hope, get away from these depressing influences; and there is one study which you will not be surprised to find that I think supremely important, and which few men have better chances of pursuing than you have in Yorkshire. I would have you, then, whenever you find it possible, make yourselves acquainted with some of the examples of our own ancient English architecture, of which the Yorkshire cathedrals, abbeys, and churches

afford such magnificent examples. I would advise you not merely to make the customary hurried and careless visit, but to sit down before them, to study their variations of style and detail, to read enough about them to be able to understand them, and finally to go to them sketch-book in hand. No study is more improving, or more interesting. And I believe that the accurate drawing of our own Medieval ornamentation and the detail will be found to be as good a training as any that can be suggested. The study of art is never so interesting, never so profitable as when circumstances allow you to see it under the conditions for which it was originally designed. We look at sculptures or paintings divorced from the buildings they were intended to adorn under the gravest disadvantages, and in your case, as with most of us in this country, it is in architecture alone that you can examine the artist's work under the very conditions for which he designed it, in purpose, situation, and surroundings. And, as I have suggested already, what I advise you to do is not merely to look at old buildings, but to make yourselves masters of something of their history, and to learn so much about the variations and development of style in architecture as to be able to distinguish one from another in a real way. It is possible for a well-educated man to say, within a very few years, at what date any of our old English buildings were erected. Try to learn to do this, and you will be quite astonished to find what a different country it is in which you move and live. Things, which to the ignorant man, or to the man without educated eyes were dull and lifeless, are replete with interest to him whose eyes have been opened to their value. You may say that this advice savours somewhat of mere antiquarianism. It is true that it does; but to know anything of any art, you must in these days know something of the art of former days, and that is to say you must be somewhat of an antiquary as well as an artist. When the South Kensington Museum sends you down a collection of examples of works in the precious metals, it is important that you should be able to judge with some accuracy as to the relation which each bears to the other. If, for instance, you are able to arrange them in their proper chronological sequence, and to tell the country in which they have been wrought, you will be able to see what it was that their makers were aiming at, and why new facilities of manufacture led to new forms or works of ornament. And if, when chance happens (as it does not very unfrequently now) to allow of your seeing galleries of pictures, the intelligent enjoyment of them depends not only on your being able to admire those with which you are most in sympathy, but equally in your being able to trace the influence of one master upon another, of one school upon another, and finally of the art of one country upon that of others. You have, no doubt, gathered from what I have said that the work before us is an up-hill business from beginning to end. Indeed, sometimes one feels disposed to despair about that general recovery of taste in this country which it is the object of schools of art to develop and foster. We see how gradually but certainly those old traditions are dying out which, even at the beginning of this century, had not lost their influence on some of our workmen. The country smith was constantly doing work which, being well executed, fitted for its purpose and natural in its treatment, had artistic qualities far above any which we can discover in much of the pretentious metal work of the present day. The country builder frequently also built a cottage or farm house, not wholly vulgar or commonplace, respectable in its honest use of materials, and, at any rate, substantial and useful in its way. And it is this quality of usefulness for the purpose which, in these and other similar examples, is that which most deserves to be noticed and remembered constantly by students. Without it no art is worthy of notice—and where it is the basis of ornament no art is wholly contemptible. In architecture, the first canon is that the building shall do its duty—first as being suited for its purpose, and next as being well and soundly constructed. And what is true of architecture is true of every other kind of work. I remember how Mr. Gladstone, when he lectured on Wedgwood's work, observed on the admirable shape of his plates, so perfect, that he did not doubt the cheese for which a dish was made must have joyed to find itself on so suitable a stand. So if you want to design a cup you must make it of such a shape as will allow of its

being easily drunk out of. Compare a chalice of the middle ages with one of the last century. You will find the former always usable with ease, the latter hardly capable of use at all. Then having got the most useful shape, the object ought to be to ornament the form, and not to conceal it. You should also always endeavour, as far as possible, to let everything explain its use easily; and not follow the example so frequently set now of concealing as far as possible the object, under some silly application of a form or thing with which it has nothing whatever to do. People nowadays hardly allow anything to do its work in a natural way. Even in our gardens a flower is not allowed to grow and flower in a natural way, but must be massed with so many others in what is called a ribbon pattern, which is simply a device for destroying all idea of nature's growth and beauty, and is an unhappy evidence of the bad taste which inflicts such mistakes on the grandest gardens, and leaves to the unsophisticated cottage garden the credit of being the only place where the old and natural use of a flower garden can be seen. Time would fail me this evening if I were to attempt to show you all the bearing of the rules I have suggested to you, and my object is rather to leave you to carry out for yourselves the principles I have mentioned, than to attempt the impossible task of giving a list of examples of their application. I have said nothing hitherto about the study and imitation of natural objects as suggestive of decoration. This is, however, a matter of extreme importance, and to which, no doubt, the attention of most of you has been called at some time or other. There are two ways of using nature in art. The one is the copying her exactly, the other is the giving a conventional imitation of her. The direct copying of natural objects is obviously proper in certain works. If you are painting a picture you must make your tree, and your rock, and your wave as like nature as you possibly can. But as it is wholly impossible to represent every leaf, every line of stratification, and every particle of foam on every billow, you are forced to a sort of conventional treatment which will enable you to produce the general effect on the eye of the things you undertake to paint. If, however, your object is to use a natural form for some purpose of decoration, as it is wholly impossible to make the work absolutely like nature, it is better frankly to accept the conditions, and boldly to give a conventionalised representation of it. Take a leaf, and you will find that its leading features are its outline, the lines of its fibres, and the way in which it grows out of the stem. Your conventionalised leaf must give you the essence of these three facts in the simplest way and with the least complexity. It was in this way that the Greeks used foliage for the decoration of their buildings, and without any knowledge of their work, it was in the same way that the best Medieval English sculptors treated the ornament of their buildings. Descend from this higher kind of work and consider how you should make use of natural objects in the design of a wall paper, of a piece of stuff, or of a merely decorative design for any flat ornament, and you will find the same rule apply. You cannot absolutely imitate nature without her texture and her tints, and therefore you ought not to make the attempt. Such works as that of Grinling Gibbons, admirably skilful as it is, must be condemned where it is used as an applied decoration of a building; for, in the first place, it is not an ornamenting of a necessary feature; and, in the next, is not really a *fac-simile* of the natural object it pretends to repeat. No caution is more necessary than this, for just as nothing is more easy than the making ornament by the combination or repetition of natural forms, so nothing is more common now-a-days, and perhaps it is not going too far to say also that nothing is more contemptible. I have said enough, I hope, by this time to show you not only how much there is to be done by students of art, but equally how difficult it is to do it. Let me give you one or two encouraging suggestions. Your Sheffield School of Art, if it does its work well, may aid in what, believe me, is of vital importance to art; it is adding one more to the local centres which are necessary if the provinces in our time are to be permeated with any proper and universal feeling for art. Such centres existed of old, and from one of them at Norwich, in the middle ages, proceeded a vast number of workmen, painters, carvers, makers of stained glass, and so forth, of whose works so much remains still in the Norfolk Churches as

to inspire one with the greatest respect for their taste and skill, whilst from another came the architects of your Yorkshire Abbeys, buildings hardly second to any in the world. In Italy, every considerable city was, of old, the centre of a school of art, and just as these local centres lost their life and power, the influence of individual painters or clusters of painters waned away, and a country in which every one was at one time an artist has become one of the most debased and backward in its art. Fortunately, revivals are possible. An art dies out altogether, is forgotten, and then, after ages of disuse, again springs into existence and flourishes. Let us hope it may be so here. But let me warn you that the conditions are hard. No man can do anything worth having without love and enthusiasm for his work. These may, however, be cultivated and developed. He can do nothing if his work does not bear the impress of his own thought and his own hand. The human character of all work is the one enduring interest it possesses. The work of a crowd of men, all obeying the orders of one, is, after all, mainly, if not solely, the work of the one whose orders are obeyed. The workmen who built a pyramid are no more to be admired than those who spend their whole lives in making pins; they have, indeed, been less usefully employed. But the workman or the student who has made one really good, original, truthful, and suitable design, has done a good work, for which he deserves all our thanks. May I be allowed to hope that in course of time some of you may find it in your power to do such work, and that all of you will endeavour to make the most of the teaching afforded by this school by training yourselves to admire and properly esteem all good work and to distinguish what is true in art from what is false, and by doing what lies in your power to stem the tide of bad taste and bad work with which on all sides we seem in these days to be inundated. Two reasons may be given for those who advocate schools of art in the centres of manufacturing industry. That which is the least worthy shall be given first. It is that, with a mere view to trade and to profit, to the sale of our goods and competition with rivals, an artistic training of the people cannot be dispensed with. If we ignore the value of the artist's aid in our manufactures others will not, and in the end we shall lose any pre-eminence that we already possess, or fail in the attempt to rival those who have already gained it. From this merely mercantile side, therefore, there can be no doubt of the interest which the manufacturer has, and ought to show, in such institutions. The second reason is of a far higher order, and will commend itself, I am sure, to the generous sympathies of young students such as those to whom I am speaking. It is that where so little is bright or beautiful about them there is no happiness so great as that which may be secured by the artistic culture to which they may here devote themselves. It is not the mere love of gain that will ever make an artist. It is the love of the beautiful and the hatred of what is hideous that lies at the bottom of all a man's real success in art. Devote yourselves heart and mind to art with such views as these, and you will be rewarded by the conviction that you have not only made yourselves happier, but have also given fresh interest and happiness to the lives of those who see and profit by your work.

A vote of thanks, proposed by the Mayor and seconded by the Master Cutler, to Mr. Street for his admirable address was carried by acclamation, and another vote of thanks to the Mayor for presiding concluded the proceedings.

THE AMALGAMATED HOUSE DECORATORS AND PAINTERS' SOCIETY.

THE sixth annual report of the Amalgamated Society of House Decorators and Painters has just been issued. The general secretary, Mr. Shipton, says:—"Fellow members,—This, the sixth annual report of our society, although not showing so much prosperity as in former years, affords us considerable ground for satisfaction. The past year has been one of unprecedented depression in every industry, and, of course, our own included. It has been a most trying and critical period for all trade associations, and yet the position of our society at the close of 1878 gives solid evidence of being able to pass through crucial difficulties, and yet have the capacity to

effect a great pecuniary improvement. During the past year our total income has been £1,000 13s. 1d., which added to the balance in hand at the close of 1877 of £989 9s. 4d., makes a total of £1,990 2s. 6d. From this sum we have expended for sickness £211 6s., and for funerals of members and members' wives £63, making a total for these benefits of £274 6s., and for other purposes £403 5s. 7½d., making a total expenditure of £677 11s. 7½d., and therefore leaving us at the close of 1878 with a balance in our general fund of £1,312 10s. 11½d., being an increase during the year of £323 1s. 6½d. In consequence of the severe and continued stagnation of every trade in the South Wales district, it has been necessary to close the Aberdare, Merthyr Tydvil, and Rhendda Valley branches, as the members had been forced to leave their homes in search of employment in other places.

"We have, however, opened a new and flourishing branch in Eastbourne, and efforts should be made in every town to open new branches in neighbouring localities where they do not exist. The exceptional prevalence of privation through want of employment is made tolerably clear by the fact that during 1877 the expenditure for sickness and funerals exceeded by £68 7s. 9d. the expenditure for the same purposes in the preceding year. After passing through the unusual vicissitudes of the twelve months just completed, we have 21 branches, 700 members, and £1,312 10s. 11½d. in our general fund. It is to be regretted exceedingly that our members have fallen off in number during the same period; but when we remember what serious losses in members and funds so many other societies have had to experience, in addition to heavy trade disputes, and, in too many cases, reduction of wages, it should be gratifying to us to know that we have thus far sustained our funds and made over £323 profit during the year. Should a period of reaction fall upon the building trades, those who leave or remain aloof from their trades organisations will be responsible for any calamity which may befall us through their criminal indifference to the only means by which their just interests can be sustained or their general welfare as men be effectively protected. On every hand, throughout the entire country, the prospects are indeed gloomy for labour. If these who are engaged in industrial toil fail to do their duty to themselves and protect their interests with an organised defence, then let senseless regrets cease, when by apathy they court the disasters they might easily prevent. In the revision of our rules it will be our duty to make such changes as may admit the local societies to become, with great advantage to themselves and others, part of our association; and that before the close of another year we shall have the great satisfaction of showing by our next report such an acquisition of members who, by their ability and influence for good, will enable us to place before the trade the position of an organisation which, for extent, solidity, and useful power will be unprecedented in our history."

TRAMWAYS.

AT a meeting of the Society of Engineers, held on Monday evening, April 21st, in the Society's Hall, Victoria-street, Westminster, Mr. Joseph Bernays, Vice-President, in the Chair, a paper was read by Mr. J. L. Haddan, on "The essentials which should govern the Construction and Working of Tramways." The author observed that when tramways were first introduced, they were a great advance upon the ordinary roads, but that the modern improvement of roadways had, in the present day, led almost to a reversal of the relative positions of road and tramway. In America, the tramways were superior to the roads, because the latter were sacrificed to the former. The tram-rail there, moreover, was available for the moderate ordinary traffic, while the speed of the tram service was about 20 per cent. greater than in this country and on the Continent. Mr. Haddan alluded to the general tendency to employ wood in roadways, and he described a system of construction by which a road could be made with a perfectly flat surface, and yet be well drained, and which should have the tramway incorporated with it. The tram-rails, he said, would be of wood, and the roadway would be kept surfaced with grit, so that the wood would not form the actual wearing surface. This system of tram and roadway, the author observes, would be homogeneous, and

would combine the best possible road for ordinary vehicles, with a perfect tramway for special carriages at less cost than the present method of construction. The author condemned the indiscriminate introduction of railway and omnibus principles into the construction and working of tramways, and described his proposed arrangement for meeting the requirements of a tramway service. This consists of a locomotive engine to be worked by steam and air, the steam being used for compressing, during the journey, its own supply of air as well as that which supplies the continuous motive power for propelling the cars. By reversing, the same driving mechanism acts as a continuous brake, and the same system is so arranged that the driver constantly feels the pull of the train upon a regulator handle. The withdrawal of his hand from this handle is to instantly cause the steam-power to block the train. Thus the brake mechanism would always be in action, instead of lying dormant as in ordinary continuous brakes. The author, in conclusion, stated what, in his opinion, were the technical, physical, and administrative requirements of mechanical traction on tramways generally.

SOCIETY OF ANTIQUARIES.

THIS Institution, pursuant to ancient customs held its anniversary on Wednesday (St. George's-day). The President, the Earl of Carnarvon, delivered the inaugural address. It was his duty, and he did it with sorrow, to mention the loss by death of nineteen members. Among these were Baron Heath, Canon Raines, Mr. W. S. Walford, and the Rev. J. G. Joyce. He then glanced at the events which had more immediately affected the Society during the past year. The first was the discussion with respect to the roof of St. Alban's, with the results of which, he thought, the Society might rest perfectly satisfied. Of the part he had himself taken, he would say nothing; but of Mr. G. E. Street's paper, laid before the Society at the opening of the session, he ventured to affirm that it had remained unanswered, and was, in fact, unanswerable. Whatever the result might be, we could afford to look on with a quiet conscience. His lordship then adverted to Sir John Lubbock's Bill for the Preservation of Ancient Monuments. He could quite understand the objections felt to the exclusion from the office of Commissioners of the Society of Antiquaries for England, of the Society of Antiquaries for Scotland, and of the Royal Irish Academy for Ireland, and of the supersession of one and all of these bodies by the trustees of the British Museum. But as her Majesty's Government had made it a *sine quâ non* that those trustees should be the Commissioners, he felt it would be unwise, as at present advised, to imperil the safety of the Bill by opposition on that ground, and he had therefore consented to take charge of the Bill in the House of Lords, and he hoped the Session would not pass without placing on the Statute Book an Act which might exercise a beneficial influence on the monuments of pre-historic Britain. Turning from the past to the future, Lord Carnarvon proceeded to pass under review some of the objects which he thought this society might with propriety, if not achieve, yet keep in view. Of these, not the least important was an archaeological survey of Great Britain. Nothing, he thought, could more effectually promote the preservation of pre-historic monuments, or facilitate the working of Sir John Lubbock's Bill. After entering into details on the facts which such a survey should embrace, Lord Carnarvon expressed a hope that this great work might be undertaken by the society with the aid of a grant from the Government, and with the use of the materials collected together by the Ordnance Survey. Nor was this the only work which, in his judgment, the society might fitly accomplish. No country, except Italy, was as rich as we were in charters, and yet we were the only civilised community that possessed no national *Codex Diplomaticus*. Everything extant ought to be printed, at least down to the region of Edward I. Then, again, if it was too much to expect what he considered was a great desideratum—a new edition of Dugdale's "Monasticon"—yet a complete series of the chartularies of the various abbeys would be a most useful work, containing, as they did, a mine of information on the social and economic history of this country, and which, if printed in *extenso*, would be put beyond the

risk of destruction by fire. Lord Carnarvon proceeded to show what valuable work might be done in editing the pipe rolls, the subsidy rolls, the episcopal registers, the municipal archives, and other documents, and then expressed a hope that from time to time as occasion might arise, and as the funds might allow, the Society might turn from the labours of the pen to those of the spade, and might contribute—as they had last year contributed to General Lane Fox's excavations—to the encouragement of original explorations conducted on systematic and scientific principles. If it be asked, where are we to find the money for the various schemes he had named in his address, he ventured to think that for any object really national an application to the Treasury would not be made in vain. It would, perhaps, be less easy to answer the question, Where are we to find the men? The labourers are few; and thankful should he be if any words of his could stir up the eminent men among those whom he was addressing to add in the manner indicated to their reputation and to the reputation of the society; but it was also not beyond the sphere of his duty, as he ventured to think, to remind the Fellows how important it was in adding to the members to insist on a high standard of qualification, and to exercise care and discrimination in proposing candidates for election. It was thus, and thus only, that they could gather and keep together a band of men who, in the words of the "obligation," which every Fellow subscribed on his admission, would "do the utmost in their power to promote the honour and interest of the Society of Antiquaries of London."

BLACK MILDEW ON ST. PAUL'S CATHEDRAL.

AT a late meeting of the Philadelphia Academy of Natural Sciences, Prof. Leidy remarked that an English periodical had recently ascribed the blackness on some portions of St. Paul's Cathedral to the growth of a hitherto undescribed lichen, which would appear to flourish only on limestone, and in situations unaffected by the direct rays of the sun. Prof. Leidy stated that his attention was called many years ago to a similar black appearance on the brick walls and granite work of houses in numerous shaded streets, especially in the neighbourhood of Delaware river. Noticing a similar blackness on the bricks above the windows of a brewery, in a more central part of the city, from which there was a constant escape of watery vapour, he was led to suspect that it was of a vegetable nature. On a microscopical examination the black mildew in this case proved to be alga, closely allied to a species which he took to be the well-known *Protococcus viridis*, and which gives a bright green colour to the trunks of trees, to fences and to walls, mostly on their more shaded and northern sides, everywhere about Philadelphia. Probably it may be the same plant in a different state, but until proved to be the same it may be distinguished as *P. lugubris*. It consists of minute round or oval cells, isolated or in pairs, or in groups of fours, the result of division; or it occurs in short irregular chains of four or more cells up to a dozen, occasionally with a lateral offset of two or more cells. By transmitted light the cells appear of a brownish or olive brownish hue. In mass and to the unassisted eye, the alga appears as an intensely black powder. Can this, asked Prof. Leidy, be the gonidial alga of the undescribed lichen of St. Paul's?

ASPHALTE AND TIMBER FLOORS.

A CURIOUS method of laying down floors has been adopted in France, and is said to have obtained a wide application. It consists in putting down flooring, not as hitherto, on joists, but in embedding the boarding in asphalt. The new floors are used mostly for ground stories of barracks and hospitals, as well as churches and courts of law. Pieces of oak, usually 2½ to 4 inches broad, 12 to 30 inches long, and 1 inch thick are pressed down into a layer of hot asphalt not quite half an inch thick in the well-known herring-bone pattern. To insure a complete adhesion of the wood to the asphalt and obtain the smallest possible joints, the edges of the pieces of wood are planed down, beveling towards the bottom, so that their cross-section becomes wedge-like. Nails, of course, are not necessary, and a perfectly level surface may be given to the

flooring by planing after the laying down. The advantages of this flooring, which only requires an even bed on which to rest, are said to be the following:—

1. Damp from below and its consequence, rot, are prevented.
2. Floors may be cleaned quickly and with the least amount of water, insuring rapid drying.
3. Vermin cannot accumulate in the joints.
4. Unhealthy exhalations from the soil cannot penetrate into living-rooms. Asphalt being impermeable to damp, rooms become perfectly healthy even if they are not vaulted underneath. In buildings with several stories, as in hospitals, the vitiated air of the lower rooms cannot ascend, an object which it has hitherto not been possible to attain by any other means.
5. The layer of asphalt will also prevent the spreading of fire from one floor to another in case of conflagration. The flooring here described has been laid in the numerous casements of the newly-constructed forts round Metz, to the satisfaction of the authorities. The cost is about a shilling per square foot. This estimate, somewhat high, would be much lower in districts where oak and labour are cheaper, and the distance from the places of construction less, and especially where there is more competition among contractors than at Metz; and the cost for larger undertakings may be reduced to eight shillings per square metre.

THE IMITATION OF WOODS AND MARBLES.*

IT is useless to preach a high-art doctrine such as that which forbids imitation of natural products, so long as a large and respectable class of our artists practise a style of decoration that is still extensively admired by the public. The question with us now is not whether painted imitations of woods and marbles, such as that produced by painters in "graining" and "marbling," is a legitimate means of decoration, still less a rational one. Such a question we should be obliged to answer in the negative. It is enough for us to know that thousands of our best decorators are so employed, and that many of our best buildings are decorated in this manner. Such being the case, we open the large folio now upon our table, entitled "School of Painting for the Imitation of Woods and Marbles, as taught and practised by A. R. Van der Burg and P. Van der Burg, directors of the Rotterdam Painting Institution, illustrated with numerous engravings and chromolithographs," many of them marvels of imitative skill. The book purports to be a complete course of instruction in the art of imitating wood and marble according to a certain method. The method of the Messrs. Van der Burgs may be summed up as founded upon a close examination of the effects of the light upon various grains; that, in fact, the colour changes its hue according to the direction of the rays of light falling thereon. The authors observe that, "if we take a piece of wood well polished and turn it round so as to make the light fall upon it from different sides, we shall at once perceive that its colour takes different hues, and the so-called 'shine' changes its place, and we may equally convince ourselves that the grain remains unaltered, whilst the 'parties' of light and chief colours, though remaining the same, change their places." The grain, in short, is not dependent upon the colours of the species of wood, but the colour changes its place according to the grain. The tools used are of a special kind, and are illustrated, the authors offering to supply any that may not be procured. It will be unnecessary to say that the work is enriched by numerous examples of imitative painting; there are 36 plates of chromolithographs, with detailed descriptions and explanations of the preparation of the colours and processes of working. Walnut is one of the woods shown. For painting it the primitive colour is composed of white, yellow-ochre, and Turkey or Prussian red. In the process of graining, the palette is filled with colours in the following order: black, Cassel earth, burnt sienna, raw sienna, and a little Prussian blue; the black is ivory black. The graining-brush is flat, with a short handle, and is held in a slanting direction, very slightly raised above the board; it should not be over-

* School of Painting for the Imitation of Woods and Marbles, by GEBR. A. R. & P. VAN DER BURG, Rotterdam. London: Crosby Lockwood & Co., Stationers' Hall-court.

charged with paint, and the side or point of brush should be filled with the darkest hue. Besides the graining-brush, the stiff brush, a comb, sponge, and washleather are employed, the latter to take off the superfluous liquid, or paint from the brush. The several positions the brush should be held in drawing the grain are illustrated, and the authors show that every grain has its beginning and end, with few exceptions; that is, the grain remains uninterrupted, and one curve follows another. We cannot, without diagrams, show the methods adopted to give the effect of oval-shaped veins, but the main secret is to fill the brush only slightly with paint, and draw the grain with the sharp corner of the flat brush. The examples of walnut, plates II., III., are wonderfully true to nature; we may also refer to the specimens of juniper-tree imitation as excellent reproductions. Mahogany, maple, ash, and other varieties are given. But the marbles are perhaps even more faithful as renderings. Thus, we have Brèche (Breccia) marble imitation in which the grey, violet, red veins, and angular crystalline masses are cleverly reproduced. Speaking generally of marble imitations, the authors say, "The paints for marble painting are mixed rather thick, with raw linseed oil; in winter, or in the open air, a little boiled pale linseed oil ought to be added, especially when slow-drying paints, such as marmum caput or coleothar, jet black, &c., are used." Paints should be sparingly used, both for facility of working and durability. Poppy-oil is recommended for the finer sort of work, as more durable, but linseed oil for outside work. The palettes for various kinds of marble are given in detail, and the *modus operandi* explained. Specimens of St. Remi marble (plates V. and VI.) are very fine; different species of white marble, such as Carrara, that from Arabia, Spain, Greece, and Italy, are given, all distinguishable by connoisseurs, by the colour and grain. Sienna marble, Vert de Mer, Waulsort marble, &c., are also beautifully illustrated and treated of in the work before us. The Waulsort marble, plate 36, is a masterpiece of imitative art and chromolithography. It may be of value to remember in wood graining, that the broadest grain lies near the heart, and becomes gradually finer, so that the coarsest comb should be used first, and then the finer by degrees. In fact, there is more rule and method in wood-graining than in marble imitation, in which materials the veins and crystalline ingredients are found embedded in the most capricious manner.

Some useful hints on outdoor painting are given in the Appendix, which, however, we find is introduced in two different places in the book, and the order of the descriptions of wood and marble imitations is somewhat irregular. To prevent cracking, the primings should be made thick; for "if oak or deal be covered with a coat of paint mixed with nothing but boiled oil, experience teaches us that the results will be bad." Brown ochre, mixed with raw linseed oil and turpentine, is said to produce good results as a priming coat. The priming for wood painting should not be too dull, or it is not easy to work upon; for marble painting it is recommended to be thin, and mixed with more turpentine. Some suggestive remarks are given at the end about ceiling and wall-painting. We take leave of Messrs. Van der Burg's work with the conviction that it will be usefully studied by all those who imitate wood and marble, as a comprehensive and somewhat scientific guide to the art. The explanations of the processes, the manipulation and management of the colours, and the beautifully executed plates will not be the least valuable to the student who aims at making his work a faithful transcript of nature.

THE PARISIAN SEWERS.

SOME particulars are given by Russell Sturges in the *New York Nation*, of the great department called "Service de la Vie Publique"—Street Department, in short—which includes within itself a number of "services" which have little in common with the streets. This department makes a wonderful show of itself, its structures, machines, discipline, and organisation. There are models on an enormous scale of the sewers of different sizes and kinds, the models in this case built of the actual materials used in the actual way, with the railways and working models of the little cars used in them, and of the

boats which float in the largest sewers. The system, now thoroughly carried out in all its details, by which all the sewage of Paris is carried to the Seine at Clichy, far below the city, below even the Bois de Boulogne, so that you can swim in the river anywhere, ride your horses into it, or fish in it with the chance of catching something—this great network of sewers, so accessible and traversable that rumour ascribes to the late emperor the intention of using them as military roads in the case of popular dissatisfaction—all this is made so clear to the student that he can escape the regulation journey through them, if he will. Here are immense plans of the water-supply of Paris, as it was anciently at different epochs, and as it is now, together with large scale drawings of new aqueduct buildings and models of some of the more important. Models of the two or three newest bridges over the Seine are also to be seen; of which bridges the very latest built is the little "Pont de Passy," just below the Exhibition grounds—a foot-bridge made necessary by the taking into the inclosure the Pont de Jéna, but which will remain as an added convenience.

Enormous plans, plans in relief and bird's-eye views of different cemeteries and parks, of the Bois de Boulogne and the Bois de Vincennes, hang under the shelter of the outside verandas. Specimens of every sort of paving and flagging, roadways and sidewalks, with elaborate tables setting forth the results of wear on each one of them; plans of street railways, with models of rails and cars; drawings and models of all the different kinds of kiosk and illuminated pavilion used along the boulevards and wider streets, and, finally, plans, views, statistics, and specimens of the establishments of horticulture and arboriculture—all go to make up such a museum of city life as the round world cannot match elsewhere. And the crowning feature, in popular estimation, is the huge model of "the meeting of two ways, a boulevard and a wide street, with the sidewalks, water-hydrants, and sewer-culverts, the paving, rails of tramway, grass-plots and trees, seats, system of lighting, office of cabs, advertising column (illuminated from within), urinoir, and kiosk of news-vender." This affair shows a piece cut right out of Paris and seen through a diminishing-glass. Here are the houses, split right down through floors and roof, showing how water and gas are laid on and how sewage is carried off; under the street-level yawn the open sewers, and the water and gas mains are there, supported by posts within the sewers or bedded in the soil; there, too, is the ingenious system by which parts of each house can be entered from the sewers through an iron grate used only for that service, and the clever invention which prevents the flooding of cellars in the worst cases of "set-back." The thing is complete, even to the gas-meter of each house, in a handy place for consultation, and the waste-pipe from every bath-tub traceable from bath-room to drain-pipe under ground.

PARLIAMENTARY NOTES.

CIVIL SERVICE ESTIMATES.—Votes to complete the following sums were agreed to last week:—£35,510 for royal palaces; £2,975 for Marlborough House; £113,561 for royal parks and pleasure grounds; £32,930 for the Houses of Parliament; £117,255 for public buildings; £15,885 for furniture of public offices; £181,331 for Revenue Department buildings; £46,750 for County Court buildings; £22,018 for Metropolitan police courts; £8,203 for sheriff court houses, Scotland; £120,300 for the new Courts of Justice; £133,500 for the surveys of the United Kingdom; £20,786 for the Science and Art Department buildings; £4,719 for the British Museum buildings; £47,476 for the Natural History Museum; £20,000 for the Edinburgh University buildings; £17,062 for harbours, &c., under the Board of Trade; £198,356 for rates on Government property (Great Britain and Ireland); £10,000 for Metropolitan fire brigade; £12,110 for lighthouses abroad; and £23,216 for diplomatic and consular buildings. In class 2, the following estimates were also agreed to:—£43,244 for House of Lords offices; £50,311 for House of Commons offices; £59,815 for the Treasury, including Parliament counsel; £89,502 for Home Office and subordinate departments; £77,490 for Foreign Office; £39,217 for Colonial Office; £30,604 for

Privy Council Office and subordinate departments.

TRAMWAYS.—The report of the Committee of the House of Lords appointed "to inquire into the regulations which it may be desirable to impose in relation to the construction and use of tramways," was published on Monday. The following summary exhibits such of the regulations which the committee consider it would be desirable to impose at the present time in relation to the construction of tramways:—1. It is desirable that, wherever it is possible, tramways should be constructed and maintained, but not worked, by the local authority. 2. The preliminary consent of the local authority to the construction of tramways by private promoters should be required as at present, with the exception that where the proposed tramway passes through the districts of more than one local authority, and those authorities differ as to whether it should be sanctioned or not, there should be an appeal to the Board of Trade. 7. No absolute *minimum* width of street or road should be laid down, and the veto conferred, under certain circumstances, by Section 9 of the Tramway Act, 1870, upon one-third of the frontagers should be done away with; but as a general rule, there ought to be at least 9ft. 6in. between the edge of the tramway and the kerb, and a *minimum* width of 24ft. from kerbstone to kerbstone; it should, however, be left to the Board of Trade to decide, according to the special circumstances of each case, what width of roadway is required to provide adequately for the safety of the public and the convenience of ordinary traffic. 8. No preference should be given to one gauge over another, but the width of gauge should be settled freely, according to the circumstances of each case, Section 25 of the Tramways Act, 1870, being altered accordingly. 9. The Board of Trade should instruct their inspectors to pay particular attention, in their inspection of tramways, before they are opened for use, to the solidity of the permanent way; and should also, in the case of existing tramways, satisfy themselves, before sanctioning the use of mechanical power, that the permanent way is constructed in a sufficiently solid manner to bear the increased wear and tear. 10. The Board of Trade should have power to regulate the width of groove to be used in the rails, so as to protect the wheels of carriages or other vehicles, as far as possible, from being caught in the grooves. 11. A tramway company which fails to keep its rails and its own part of the road in good condition and repair, in accordance with the requirements of Section 28 of the Tramways Act, 1870, should be made liable to a penalty not exceeding £5 a day.

COMPETITION.

RAMSOATE.—At a special meeting of the Local Board Commissioners it has been resolved that Mr. James Abernethy, vice-president of the Institution of Civil Engineers, should be engaged to adjudicate on the designs sent in for the proposed new road, and that he be paid a fee of 100 guineas. In reply to a member, the chairman said Mr. Abernethy would simply award the premiums, and then it would come before the ratepayers to select a plan.

A new reredos has just been placed in All Saints' Church, Cokermonth. It is constructed of oak, consisting of three panels, in tracery, with buttresses. The centre panel is finished with a canopy and bold finials, and bearing a Maltese cross, with the monogram I.H.S., on either side of which are passion flowers. On each side of the reredos are two panels, in oak, bearing the Decalogue, Lord's Prayer, and Apostles' Creed, illuminated on metal, the dado being formed of Minton's encaustic and majolica tiles. The oak work was prepared by Mr. John Hunter, of Cokermonth; whilst the Decalogue, &c., was the work of Mr. John Scott, of Carlisle; and the carving is by Mr. R. Little, of Carlisle. The designer of the whole was Mr. W. C. Jennings, architect, of Cokermonth. The cost of the work amounted to about £100.

The tender for the erection of the proposed new schools and cottage homes at Withington, in connection with the workhouse extension scheme, has been accepted by the Guardians; but as the amount is £2,000 above the sum which the Board obtained power to borrow, the work, it is feared, will not be proceeded with as early as was expected. The accepted tender, that of Mr. J. Herd, was selected from 11 others. The highest was £19,180, and the lowest, £15,190. That of Mr. Herd was for £16,924.

Building Intelligence.

ADEL.—The church of St. John the Baptist, Adel, near Leeds, was last week reopened. The edifice is one of the most perfect examples of Norman architecture, and is supposed to have been erected about 1140. In the interior, the chancel arch, usually the point of special attention to Norman builders, is remarkable in a small country church for its height, 15ft., and width of span, 12ft. The building having recently fallen into decay, it was resolved about twelve months ago to close it for repairs. It was also resolved to raise the roof of the edifice, which at some period appears to have been depressed—to its proper pitch. This has now been done. A number of modern windows have been removed, and restored to their ancient type, and the unsightly vestry has been replaced by a detached octagonal one. The gallery which formerly existed at the west end of the church has been removed, along with the narrow pews; the nave and chancel have been seated with oak; and the walls have been cleared of plaster. The chancel has also been laid with encaustic tiles, and new doors have been provided in various parts of the church. A new heating apparatus has also been put down. The cost of the work is estimated at about £1,500. The restoration has been carried out by Mr. G. E. Street, R.A. (diocesan architect).

BATH.—The foundation-stone of the new college at Bath was laid on Tuesday. The architects are Mr. T. Hine, of Plymouth, and Messrs. Wilson, Willcox, and Wilson, of Bath; and the builder is Mr. J. Long, of Newark-street, Bath, whose tender was £6,180. The front elevation of the new building will be in the Classical style, to harmonise with Vellere and its portico. It is proposed to have a colonnade to connect the present and new structures, and it will be so formed as at a future time to constitute the entrance of a chapel or lecture-room built between the two. On the ground floor there are to be six class-rooms about 20ft. square, and secretary's, clerk's, and other offices. On the first floor three similar class-rooms will be provided, and a schoolroom 60ft. by 30ft. The same floor will also contain the masters' apartments.

BELFAST.—The new Presbyterian Secession Church, Botanic Avenue, Belfast, has just been completed. The external walls of the church are executed in Serabo stone with strings of Donaldson stone. The façade of the church is relieved by a slight projection flanked with buttresses; a large four-light window, with pointed head and cusped tracery, filling the upper portion of it. The style is Early Gothic. A commodious manse, in keeping with the church and adjoining it, has been lately erected. The general contractor for the work is Mr. Martin Curry. The architects from whose plans and under whose superintendence the buildings have been erected are Messrs. Young and MacKenzie, Denegall-square East, Belfast.

BELFAST.—A new hospital for sick children has been erected in Queen-street, Belfast. The Queen-street front is of cut stone in the Queen Anne style; the rest of the building has been executed of perforated red bricks. Mr. William McCammond, of Brookvale-terrace, Antrim-road, has been the general contractor. The gates and railing are by Messrs. Musgrave and Co., Limited. The cost of the whole has been upwards of £5,000, and all has been done from the designs and under the superintendence of Messrs. Thomas Jackson and Son, architects, of Belfast. The flues to carry off used-up or impure air are in proximity to the smoke-flues, there being influx of fresh air also by means of Sheringham's patent ventilators. Boyle's patent ventilators have been introduced at highest level of each staircase to ventilate them and the corridors.

CHELTONHAM.—A new church of St. Matthew was consecrated at Cheltenham on Thursday in last week. It is constructed of stone, and seats 1,400 worshippers. The style is Early English, with the smallest possible amount of ornament. It comprises nave and aisles, with vaulted entrance porch at the north-west corner, beneath the tower, upon which a spire has yet to be built, a chancel, aisles, and vestry, galleries in the transepts, and an ambulatory on the south side. The nave is 104ft. in length by 40ft. wide, and is divided into 7 bays, the two easternmost ones narrowing

in the width of the nave to that of the chancel, which has an apsidal termination. The nave columns are circular, and of dark grey stone, with a beading of white stone, at the half of their height, the capitals terminating with a plain ogee. Some of the capitals in the chancel are carved, as well as the gargoyles, and the panel over the porch. All the windows are plain, except the rose light at the west end and the large east window, which are worked in plate tracery. The organ is placed in one of the bays of the chancel. The roof is wainscoted in plain wood, and the seats are open and stained. The pulpit is of stone, with Lizard marble panels, and there are panels of the same marble at the apsidal termination of the chancel. The tower and spire, when completed, will rise to a height of 190ft. The present contract for the building amounts to over £14,000, but the entire scheme would involve a cost of £18,000. Mr. Evan Christian, of London, is the architect, and Mr. A. Estcourt, of Gloucester, is the builder.

HAWICK.—The fountain erected to the memory of the late Dr. John Douglas was placed in the Wellgate Cemetery last week. The style is Gothic. The arch is supported by four pillars, with foliated capitals resting on a base 6ft. square at the bottom. Surmounting the arch is an octagonal spire, terminating in a broad mould and finial of carved fern foliage. The height of the fountain is 20ft. The basin, which is of rock-work, is placed between the pillars. Mr. Lawrence Beveridge, architectural sculptor, Edinburgh, is the contractor.

LINTON.—The parish church of Linton, Cambridgeshire, has been reopened after the restoration of the chancel and Millicent chapel, from the designs of Mr. J. Cory, of Carlisle, architect to Pembroke College, Cambridge, the lay improprators. The original open wooden roof which had been ceiled is now exposed to view, windows on the north and south of the chancel and the priest's door have been reopened, the mullions and stone-work repaired, and a new lead roof placed on the chapel, and the windows filled with tinted glass. An oak reredos, carved by Mr. Godbold, of Harleston, from the architect's drawings, extends the whole length of the east end, with returns north and south, in which the only remaining pieces of the old screen have been worked, and new altar rails and prayer desk of carved oak have also been added. Mr. Whitehead, of Saffron Walden, executed the masonry; and Mr. D. P. Day and Mr. Chappell, both of Linton, the carpenters' work, and the glazing and lead work respectively. A new organ has been erected by Mr. Hunter, of Kennington-road, London.

ROSS.—The foundation stone of a new dispensary and cottage hospital at Ross, Herefordshire, was laid on Tuesday week. In the autumn of last year the committee sought by advertisement for designs for their proposed new buildings. Some eighteen architects sent in plans, and after consideration three out of the number, marked respectively "Well considered," "Light and air," "Thorough," were returned for final decision, when the first named, being the production of Messrs. Haddon Brothers, of Hereford, Malvern, and London, architects, was unanimously adopted. The greater portion of the edifice is but one storey high, and contains on the ground floor, ward for males, as also ward for females, having a capacity of 1,200 cubic feet, for four beds in each, fitted with lavatories. The remaining portion of ground floor is occupied by a nurse's sitting-room, a fire-proof staircase, store rooms, kitchen, scullery, and larder, coals and other out-offices, as well as a mortuary. On the upper storey is a special ward for isolated cases, and nurses and servants' bedrooms, &c. The walls are to be built hollow of brickwork, and the roofs covered with Broseley tiles. The contract sum is £1,200, and the work is being carried out by Messrs. W. and J. Crowe, of the City Saw Mills, Hereford.

STRATFORD-ON-AVON.—The Shakespeare Memorial Theatre at Stratford-on-Avon was opened on Wednesday. The building, of which Messrs. Dodgshun and Unsworth, of 13, Buckingham-street, Strand, are the architects, was illustrated and described by us in the BUILDING NEWS of September 15th and 22nd, 1876. The theatre is small but compact. The length from front north to south is 94 feet; from east to west 79 feet, inclusive of projections for tower and turret. The north end is occupied by the stage. On the mezzanine floor there are seven dressing-

rooms. Under the pit, on the same floor, is a spacious apartment to be used for storage purposes. The stage is on the ground floor, and is 37 feet by 46 feet, at the back of which are the property-room and the green-room. The width of the proscenium is 26 feet, the height 27 feet 6 inches. The pit is 36 feet by 38 feet, horseshoe form, supported by massive brick piers and wrought-iron girders. At the back of the pit there are stairs communicating with the south entrance. The pit has on the outside a corridor, 5ft. wide, having three doorways, exclusive of the principal entrance. The pit corridor and vestibule are laid with tile paving. Adjoining the vestibule is a ladies' cloak-room; solid York-moulded steps, having ornamental iron balusters, English oak handrail and moulded dado framing, lead from the vestibule to the dress circle, which affords accommodation for four tiers of chairs. Above the dress-circle is the gallery, consisting of four rows of raised seats, supported by wrought-iron girders, and extending over the pit to the same line as the dress-circle; running round the back is a corridor similar to that communicating with the pit. On the same level are the flies and artists' room. The roof over the auditorium is supported by wrought-iron principals; that over the stage is of a lighter description, the principals and tie-beams being bolted together with iron rods, shoes, and straps. The roof is of Eureka green slates. There is a circular turret on the east side of the building, the height of which is 64ft., and which affords private communication from the mezzanine floor to the dress-circle, gallery and flies, and also communicates with the stage. In the tower are three rooms. A large iron tank carried on wrought-iron girders affords provision in case of fire. The topmost room of the tower gives an excellent view, being at a height of 82ft. The auditorium is lighted by a sun burner. The building is of red brick, with stone dressings. All the stairs and landings are of hard York stone, and the woodwork generally of Christiania yellow pine. There is a dado framing to the vestibule, orchestra stalls, and gallery. From the line of concrete to the finial of the principal tower the height is 113ft. On the south side of the building from the concrete to the eaves is a distance of 42ft., of which there are 34ft. of brick and stone work surmounted by rustic work set out on stone brackets, forming the corridor to the gallery. The walls average 3ft. in thickness, and those of the tower 3ft. 6in. All the doors open outwards. The style of the Memorial is principally Early Elizabethan, which will harmonise in some measure with Shakespeare's House; and room can be made, if necessary, for a thousand persons.

TINSLEY.—On Saturday the Archbishop of York opened a new church at Tinsley. Mr. George Edmund Street, R.A., is the architect. The church is built of stone in the Flowing Decorated style, and contains chancel, nave, north aisle, organ chamber, and vestry. The chancel is 26ft. long, and 18ft. wide; and the nave 63ft. long, and 24ft. wide. The aisle is 10ft. wide. There are two entrances to the main building, through a porch on the south side and a door on the west. Above the porch there are carved crockets, whilst at some distance away is erected a lychn-gate. The church is roofed with tiles, and at the east end is a turret containing three small bells. The church is dedicated to St. Lawrence, and will accommodate 380 persons. The total cost is about £5,000. Mr. Arthur Hodgson has been clerk of the works.

WEST KNOYLE.—The parish church of West Knoyle, near Mere, Wilts, was reopened after complete restoration on Thursday week. The church has been newly roofed, that in the nave being of open timber work, and that in the chancel of pitch-pine pannelled. The chancel is fitted with carved oak benches, and a new tiled floor. A new reredos and a new pulpit of oak have been added, and also a new font of Bath stone. The porch has been entirely rebuilt, chiefly of the old materials. The tower has been repaired and the bells rehung. An organ-chamber and a vestry have been added to the church. Tisbury stone has been chiefly used in the work of restoration, which has cost £1,800. The architect was Mr. J. M. Allen, of Crewkerne, and the builders, Messrs. Osborne and Son, of Shaftesbury, and Mr. Davis. The wood has been executed by Mr. T. Osborne.

Mr. John Day has been appointed surveyor to the Bedford General Infirmary and Fever Hospital.

More than Fifty Thousand Replies and Letters on subjects of Universal Interest have appeared during the last ten years in the **ENGLISH MECHANIC AND WORLD OF SCIENCE**, most of them from the pens of the leading Scientific and Technical Authorities of the day. Thousands of original articles and scientific papers, and countless receipts and wrinkles embracing almost every subject on which it is possible to desire information have also appeared during the same period. The earliest and most accurate information respecting all new scientific discoveries and mechanical inventions is to be found in its pages, and its large circulation renders it the best medium for all advertisers who wish their announcements to be brought under the notice of manufacturers, mechanics, scientific workers, and amateurs. Price Two pence, of all booksellers and news-vendors. Post free 2½d. Office: 31, Tavistock street, Covent-garden W.C.

TO CORRESPONDENT.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 33f. 30c.). To India (via Southampton), £1 6s. 6d. To any of the Australian Colonies New Zealand, the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

N.B.—American and Belgian subscribers are requested to remit their subscriptions by International P.O.O., and to advise the publisher of the date and amount of their remittance. If the last-mentioned precaution is omitted some difficulty is very likely to arise in obtaining the amount. Back numbers can only be sent at the rate of 7d. each, the postage charged being 3d. per copy. All foreign subscriptions, unaccompanied by an additional remittance to cover the extra cost of forwarding back numbers, are commenced from the next number published after the receipt of the subscription.

Cases for binding the half-yearly volumes, 2s. each.

RECEIVED.—J. B.—Mrs. C.—W. G. and S.—E. B. and S.—W. F. W.—T. B. J. C.—R. M. and Son.—G. N.—T. S.—H. J. C.—C and S.—B. S.—T. L. B.—B. Bros.—M. R. C.

BROSELEY. (His address can probably be obtained from the source indicated. We do not know it.)—R. B. HESLOP. (St. Peter's, at Rome, was commenced by Bramante, and continued under the direction of Raffaele, Gisendo, Guiliamo di San Gallo, Peruzzi, Antonio San Gallo, Michael Angelo, Jacopo della Porta, Domenico Fontana, Pirro Ligorio, and Carlo Modona.)

"BUILDING NEWS" DESIGNING CLUB.

DRAWINGS RECEIVED TOO LATE.—"Triangle in Circle." (Piquant, but not good in angle bay.)—"Omega." (A correct and ornate Late Gothic design, with good arrangement of entrance to middle shop.)—"Try Again." (Wasteful, but shows improvement.)—"Be Mindful." (Ditto.)—"Dunwich." (We find your design was noticed under "Norwich" by a misprint.)

Correspondence.

LIGHT AND AIR.

To the Editor of the BUILDING NEWS.

SIR,—I have read with much interest a paper on the above subject in your last week's issue, in which, however, I find it stated repeatedly that a prescriptive right to an easement is obtained by twenty years' enjoyment.

Allow me to ask Mr. Ball if it is not now the case that twelve years' enjoyment confers such a right? The alteration has, I think, been made by an Act passed so recently as last Session.—I am, &c.,

Temple Club, Arundel-street, Strand. T. R. S.

SPECIFYING TIMBER.

SIR,—In the article in your paper of the 11th inst. on "Varieties of Building Timber," you very justly state that the varieties "are not easily distinguished by those who have had little experience in building operations."

My experience leads me to suppose that this difficulty is not confined to novices in the building art; in fact, I much doubt whether any ordinary engineer or architect not specially acquainted with the timber trade can ensure that

he be supplied with any particular brand he may specify; he certainly cannot do so if he has to deal with a shifty contractor without great trouble.

The question has occurred to me whether it is necessary to rely on brands and trade marks at all.

What we require is sound timber, which shall be equal to certain strains, and in some cases be of a given colour, grain, &c. Why not specify the timber, not by its brand, trade mark, or port of shipment, but as of a certain wood, sound, seasoned, free from shakes, sap, &c., &c., and that samples of a certain size shall under certain conditions bear a given strain, transverse or otherwise.

If this was the general custom, the strength required for all ordinary purposes would soon be ascertained by experiment and become generally known; and those superintending building operations would have a satisfactory test that the timber used was suited for the purpose intended.

The present system seems to me very vague and unscientific.—I am, &c.,

HAMILTON TOVEY, Major R.E.
Waltham Abbey, Essex, April 21st.

DANGER OF CREOSOTING TIMBER!!!

SIR,—After making a study of creosoting timber for over 13 years, and collecting a vast amount of information on the subject, both *pro* and *con*., and finally settling down to the belief that, if properly carried out, it is a good and just thing to do, judge of my surprise upon reading on p. 412 of your last number that a witness, in speaking of a fractured post, says "the rotten condition of it was due to its having been creosoted, as the process caused timber to be hermetically sealed, and thus the juice of the wood was not allowed to pass off, and rottenness in the centre was the unavoidable result."

These strictures must really apply to a post which has simply been paid over with a coating of tar on the outside only, regardless of the interior condition of the timber. There is a wide difference between this and creosoting, for, if the witness has studied the subject at all, he ought to know that the juice (sap) and air are extracted before the creosote is injected. As for the assertion, "it had been found by experience that creosoting was a failure," I am more than amazed by it, for our dock and harbour engineers, railway contractors, telegraph engineers, &c., &c., use creosoted timber to a very great extent.

There must evidently be something very wrong either on the part of witness or else on the side of these engineers and contractors, for why do they continue its use if the process has been proved a failure?

If this gentleman, or any of his friends who have formed an adverse opinion to the virtues of creosoted timber, applied to the Secretary, I feel sure he would, in his usually kind and obliging manner, send them a copy of Mr. Brain's paper, read before the Society, and fully criticised by a large meeting of members, which contains a very good description of the process and the very good results attained by the use of CREOSOTED TIMBER.—I am, &c.,

A MEMBER CIVIL AND MECHANICAL ENGINEERS' SOCIETY.

7, Westminster Chambers.

SIR,—For the first time in my experience, I learnt on reading the article on page 412, last number, that creosoting detracted from the strength and durability of timber.

On the 26th ult., Mr. James Siveright, Superintendent of Government Telegraphs at the Cape, read a paper before the Society of Telegraph Engineers, in which he says, "Fir grows around Cape Town, but nothing short of creosoting will make it last."

Now, whom am I to believe—the gentleman who gave evidence as stated in your article, or Mr. James Siveright above mentioned? One or the other must be wrong.—Which is it?

On asking my chief, he says "Creosote your piles with 8lb. (sp. gr. 1,000) per cubic foot, and see that you get it."—I am, &c.,

ASSISTANT ENGINEER.

BUILDING MACHINERY.

SIR,—Under the head of "Building Machinery," in your issue of April 18th, I noticed the following remarks on the subject of "scaffolding":—

"To name another clumsy, blundering plan, rendering our workmen liable to all manner of accidents, just look at our system of scaffolding with fixed poles and cords. How long will this muddling plan prevail, we wonder? Here there are signs of improvement, however, as an excellent invention has been introduced for using square timber Something far better, and by no means difficult to arrange, would be a platform of light ironwork, raised six inches, say, at a time by hydraulic pressure or a simple rack and pinion."

If some particulars of what has been done of late, without the employment of the usual scaffold-pole, or the square timber arrangement referred to by you, will be of interest to your readers, I shall be glad to forward a description and sketches of a scaffold used in the erection of one of my buildings—a Gothic church.

This building, including a tower about 90ft. high, was built with merely one stage of scaffolding, instead of a series of stages, as is ordinarily the practice.

After the foundations had been put in, and as much walling built as could be conveniently accomplished by the workmen whilst standing on the ground, the scaffolding was placed in position—that is, a single stage of scaffolding only—the top of the work then built being about 12 inches above the level of scaffold boards. Two feet six inches of walling was next built from this scaffold platform; then the whole range of scaffolding was screwed up a distance of 2ft. 6in.; another height of walling (2ft. 6in.) was then added, and the scaffolding screwed up another 2ft. 6in., as before; and so on, until the full height of wall had been built as required.

On the tower, where I more particularly timed the work, it was found that the workmen could cease walling, screw up their scaffold the required 2ft. 6in., and be at work on the walls again, in from 12 to 16 minutes—this being accomplished without clearing the scaffold of a single piece of stone, hoisting tackle, or mortar-board, the scaffold, workmen, and materials all travelling up together.

I may state that the work was double scaffolded—that is, it had the scaffolding platforms on both sides of the wall—an arrangement which, I think, would be more generally adopted where the scaffold-poles prevail, were it not that such a duplication of the parts about doubles the cost. In the case I am describing, the cost entailed was represented by the price of the extra scaffold platforms and a few slings—nothing more.

With a view of placing the "wallers" in as good a position as the "shed-men," a portion of the scaffolding was covered in, and the work was carried on in wet weather the same as in dry, the covered scaffold being as easily and as quickly screwed up as the other portions.

This covering in of scaffolds opens up a question for the careful consideration of the builder. If machinery is to pay a fair dividend for the money invested in it, it must be kept running; and if builders are to secure a good return for the money spent upon plant, they should be able to keep that plant at work, instead of letting it lie idle whenever there is a day's rain. The general adoption in towns of such an arrangement as I am here advocating, by facilitating building operations, would be a boon to the public at large, and cause us to hear less of the "hoarding nuisance."—I am, &c.,

JOSEPH J. LISH.

1 and 2, Bucklersbury, Cheapside, E.C.,
April 22nd, 1879.

HOUSES AT MANCHESTER AND NORTHAMPTON.

SIR,—Your *exposé* of architectural piracy last week did not surprise me. I was struck with the transparent coolness of the matter some years ago, but after calling Mr. Godwin's attention to it I thought no more of the affair. I believe Mr. Godwin considered it beneath his notice, or, at any rate, would not "trouble the waters" himself. Still, I think every lover of fair-play in design will endorse your action. I can almost guess the "excuse" that the Manchester architect will offer:—"Purely a coincidence"; "Similarity of mind in the authors"! Surely this sort of thing is worth the serious attention of the Manchester Society of Architects. Let us hope the "unfortunate imitator" will receive proper chastisement from his fellow-members, for clearly he has not too much

modesty, from the fact of his actually building this house to live in. After all, it is evident he preferred Mr. Godwin's ideas to his own.—I am, &c.,
BIRCH ROB.

SIR,—“Murder will out,” even in architectural copyism; but before condemning the lively and spirited architects who have come out in such brilliant colours, one ought, I think, to inquire whether they have any arrangement with Mr. E. W. Godwin to reproduce his design.

Churches by the score bristling with originality have emanated somehow from this enterprising firm; but of all their creations possibly this house is one of their best, still “they all do it.”

Strange to say, I know of an admirer of a chapel of theirs, once taking the liberty of sketching it from the road, when the gentleman who never used other people's ideas approached and saucily ordered him off. Other characteristics might be added; but perhaps the Manchester house is a pill large enough for the present.—I am, &c.
HARRY.

WESLEYAN CHAPEL COMPETITION, SWINDON.

SIR,—I see by the *North Wilts Herald* of last Saturday date that the foundation stone of this chapel was laid on the 16th inst., and a public meeting was afterwards held in the Corn Exchange of that town, when, in the course of some remarks, the chairman stated the buildings would cost £4,891 8s.

Some time ago the committee advertised for plans for this chapel, and one of the conditions stated the buildings were not to cost over £2,000. I ask, is it justice to the other competing architects for a plan to be selected, the cost of carrying out the same being more than £2,000 above the stipulated amount?—I am, &c.,

April 23rd, 1879. A LOVER OF JUSTICE.

CHIPS.

A new Congregational Church was opened at Mount Pleasant, Hastings, on Tuesday. Mr. T. Elworthy was the architect, and Messrs. C. and E. Harman were the contractors.

The Burton-on-Trent Rural Sanitary Authority have under consideration plans, prepared by Mr. Walker, C.E., of Cannock, relating to the sewerage of Barton-under-Needwood. Mr. Walker recommends that an entirely new system of sewerage be laid down, and that the sewerage should be disposed of by irrigation. The cost of the scheme is estimated at £2,700.

The credit allowed in the timber trade on the Clyde has been shortened since the commencement of the present month from six months, or a discount of 3 per cent. for cash, to four months' credit, or a discount of 2½ per cent. for cash.

Works of sewerage are being carried out at Catthorpe and Holymoorside, Derbyshire, from the plans of Mr. Gould, surveyor to the Brampton Sanitary Authority.

It is proposed to raise £1,000 in shares in the town of Romford for the purpose of altering the old Congregational Chapel in North-street, in that town, so as to fit it for use as a literary and mechanics' institute.

The county magistrates of Essex have approved plans prepared by the county surveyor (Mr. Stock) for the erection of a new recreation room and dining-rooms at Breatwood Pauper Lunatic Asylum, at an estimated cost of £4,500.

The town commissioners of Surbiton-on-Thames have accepted the tender of Messrs. Turner, of Liverpool, to do 5,000 yards of asphalt at 1s. 9d. per yard.

A provisional order has been granted by the Board of Trade to the North London Suburban Tramways Company, who are the promoters of a new line of tramways, of about ten miles in length, from Stamford Hill to Cheshunt, via Tottenham and Edmonton. An exceptional clause in the order is that the Edmonton Local Board have secured powers requiring the promoters to use in that parish such materials and mode of construction for surface and foundation of road as they shall judge best. The Middlesex county magistrates will also compel the promoters to maintain the whole of the bridges and 100 yards of the approaches on either side which may be crossed by the line.

The *Temps* announces that the boring of an artesian well for the purpose of investigating the nature of the chalk layers through which the submarine tunnel between France and England is to pass, was resumed on the French coast at Sangatte on the 1st of March last.

Intercommunication.

QUESTIONS.

[5745].—**Wood Roofs.**—Will any reader kindly inform me the following:—After having ascertained the strains on the various parts of a roof truss, how am I to get the scantlings of the various parts in a wooden roof to bear the strains? I should like a reliable formula.—NIL DESPERANUM.

[5746].—**Plastic Slate.**—I have several times lately come across the term “plastic slate roofing” in American specifications. Is this “plastic slate” some new Transatlantic building material or only a Yankee name for roofing felt?—KAPPA.

[5747].—**Geological Tour in Wales.**—I am desirous of taking two weeks' tour through North Wales for the sake of information on geology. Will some one tell me the best route to take so that I may see the most natural sections?—W. F. W.

[5748].—**Museum Plans.**—Is there any work showing plans, &c., of British, South Kensington, or Peel Park, Salford, Museums, or any book giving assistance in designing such structures?—R. A. P.

[5749].—**Quantities.**—I have a short time ago prepared plans, sections, and quantities. On the day for the tenders being sent in my employer said he objected to me receiving the usual 2½ per cent., therefore none of the tenders were accepted. A few days later the employer himself wrote copies of the quantities furnished by me, and sent them to various contractors to obtain tenders which in many cases failed so to do. He has objected to pay me anything more than for the plans. I likewise gave him a copy of the quantities, &c., before they were sent out, of which he approved. What shall I do?—A. B. O.

[5750].—**Litigation.**—Will some one kindly tell me—1st, whether there are some or many instances when architect appears in court against his client and in favour of the builder as to extras, and, if so, please cite some of them! The particulars of my case are as follows:—I was commissioned by a public Board to prepare plans and specifications for certain buildings, and to superintend over the erection. The contract was £500. At the completion I made an appointment and met the builder and two gentlemen of the Board to inspect the building. I found everything done to my satisfaction. But as there were some deviation from plans made according to the wish of the Board, I made a statement of the same, naming in detail on one side “as per plan,” and on the other “as built.” The balance was in favour of the builder of something under £5. I gave the builder a certificate of completion, but the Board refused to pay the balance. 2nd. Is my reputation not at stake if I do not go to court (at the request of the builder) in favour of justice, and prove that I am right in my statement?—A YOUNG ARCHITECT.

REPLIES.

[5726].—**Rolled Joists.**—ERRATA.—In last week's reply for $W = \frac{cad}{L^2}$ read $W = \frac{cad}{L}$. L is the breaking weight in tons on the centre.—H. A.

[5728].—**Coloured Building Stone.**—Like your correspondent “G. H. G.,” I do not know any stone by the name of Findon. Possibly “W. W.” means Finsdale, which is brought by water to London and is a light grey ferruginous sandstone of a warm tint. Speaking of coloured stones, your correspondent “G. H. G.” I think rather overdoes the matter, as I assume that “W. W.” wishes to have variegated colours for decorative purposes. It would be better to class them as red, blue, white, and grey. Commencing with the red (brick red) the best in colour are Corshill, Mansfield, Dornfries, Dumbarton, Carlisle, Woolton, Runcorn, Ardrossan, Upper Arley, and Newbiggin, some of which are hard, fine, close-grained sandstone, others soft and friable. Blue stones: Blue stones range in colour from a fine dark blue to a soft or French grey. The following are a few of their names:—viz., Pennant, Dean Forest, Cunliffe, Haadsworth, Thorpe Lane, Greenmoor, Robinhood, Knottingley, and Maninghen. White stones: Craigleith, Dalmeny, West Pines, Coxbench, Ambersley, and Hollington. Grey stones (warm grey): Wild Carr, Spinkwell, Scothall, Finsdale, and many others. The whole of the foregoing are fine-grained sandstones. The colours of the Oolitic limestones are too well known to need repetition. There are many variegated marbles and granites, but these are not generally enumerated under the head of coloured stones. If your correspondent will communicate with me I will show him numerous specimens of coloured stones.—SAMUEL THICKETT.

[5737].—**Load on Beam.**—The relation between the forces of weight and support is determined by the proportion between the segments. If a beam be supported at both ends and loaded as in the figure, the pressures on the

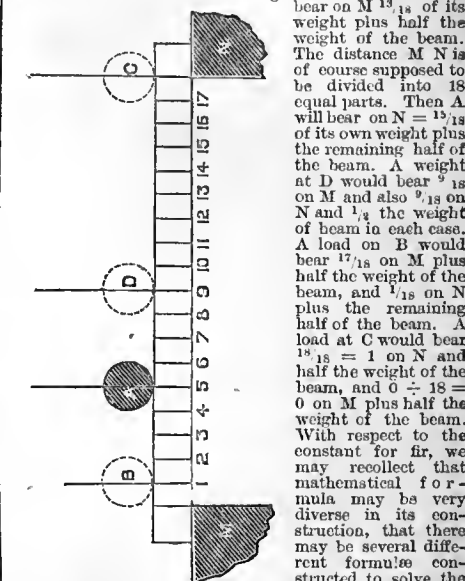

supports are as the segments. Thus if the two segments of the beam are called m and n , the pressure on the left support equals weight $\times \frac{n}{m}$ and that on the right weight $\times \frac{m}{n}$. In a beam the breaking weight is inversely proportional therefore to the product of the segments.—G. H. G.

[5737].—**Load on Beam.**—Let the beam A B be

regarded as a lever, on which the force is applied at the point W, the fulcrum being at A, then by the principle of the lever, the proportion of the load or reaction on B $\times 18$ = the total load $\times 5$, therefore the proportion of the load on B = $\frac{W \times 5}{18}$, and the proportion on A is, of course,

the difference between that on B and the total load. The constant S, for fir or other materials is given in tables or can be found by experiment. Given the breaking weight = W, the length = l, the breadth = b, and the depth = d of a piece of fir. Then S can be found from the formula $Wl = S b d^2$. The weight must be suspended from the centre of the specimen.—J. L.

[5737].—**Load on Beam.**—The pressure of the load will be inversely as its distances from supports. An enunciation of the principles involved belong to a lever of the first order, where the fulcrum is between the weight and the power. In our case the fulcrum will be represented by the load. Let us take the case where the distances are 5 and 13, then the weight A as per sketch will bear on M $\frac{13}{18}$ of its weight plus half the weight of the beam. The distance M N is of course supposed to be divided into 18 equal parts. Then A will bear on N = $\frac{13}{18}$ of its own weight plus the remaining half of the beam. A weight at D would bear $\frac{9}{18}$ on M and also $\frac{9}{18}$ on N and $\frac{1}{2}$ the weight of beam in each case. A load on B would bear $\frac{17}{18}$ on M plus half the weight of the beam, and $\frac{1}{18}$ on N plus the remaining half of the beam. A load at C would bear $\frac{18}{18}$ = 1 on N and half the weight of the beam, and $0 \div 18 = 0$ on M plus half the weight of the beam. With respect to the constant for fir, we may recollect that mathematical formula may be very diverse in its construction, that there may be several different formulae constructed to solve the

same problem, and that a letter, a symbol or constant fitting one formula might and probably should be considered as inapplicable to any other unless proved otherwise.—H. AMAROSE.

[5742].—**Drainage.**—An owner or occupier can only be compelled to drain his house into any sewer which the local authority are entitled to use, and which is not more than 100ft. from the site of such house (see Public Health Act, 1875, sec. 23).—WEST DERBY.

STAINED GLASS.

CAMBRIDGE.—The Society of King's College have just completed two important additions to their collegiate buildings. The great west window of the chapel, which has hitherto remained plain and uncoloured, unless a very doubtful tradition is to be believed, has been filled with stained glass in the style of the other windows. The composition, which is one of the largest ever executed in England, represents “The Last Judgment,” and will fairly bear comparison with the rest of the stained glass, which dates from the reign of Henry VIII. The window is the gift of Mr. Francis Edmund Stacey, M.A., formerly a Fellow of the College, and has been executed by Messrs. Clayton and Bell, who have been engaged upon the work for nearly two years. Besides this window, a fountain with the statue of the founder has been erected in the centre of the great court. King Henry VI., clad in Royal robes with crown and sceptre, holds in his hand the charter of the College. He stands on a pedestal of considerable height, and below him on each side are sitting figures of Religion and Philosophy. The water issues from the mouths of two dolphins ridden by *amorini*, and falls first into a basin fringed with dolphins, and finally into a third basin on the level of the turf. The money to provide the fountain and statue was given to the College some fifty years ago by Mr. Davidson, one of the Fellows, and has since been allowed to accumulate. The work has been executed by Mr. Armistead, R.A., the well-known sculptor of the bas-reliefs of the Albert Memorial.

The west window of Willingale Church has recently been filled with stained glass. The window is of three lights with tracery over, and in the perpendicular style of architecture. In the centre light is painted the subject of the Resurrection, and the side lights are respectively filled with the Raising of Jairus's Daughter and the Raising of Lazarus. The tracery is filled with angels, while beneath the side lights are kneeling angels facing towards a memorial catafalque, which occupies the lower portion of the central light. The design was made by the Rev. Ernest Geldart. The work was carried out by Messrs. Saunders and Co., of 75, Endell-street, London.

STATUES, MEMORIALS, &c.

CITY-ROAD WESLEYAN CHAPEL.—A new departure in the fashion of memorials to Methodist worthies is marked in the memento of the late Rev. Samuel Dousland Waddy, D.D., just placed in the old chapel in the City-road by his son, the well-known J.C. and M.P. The pillars which supported the gallery, and the pilasters on either side of the communion recess were mere stucco shams. These Mr. Waddy has had removed, and replaced by massive granite and marble masonry. The shafts of the pillars, weighing about one and a half tons each, are of polished Aberdeen red granite, in monoliths. The capitals are of statuary white marble, carved in the Corinthian order. The pedestals are in polished red Devonshire marble, the moulded caps and bases being of black Devonshire marble. The recesses for the pillars are lined with polished marble. A memorial inscription is incised in gilded letters on the left-hand pedestal. The statuary work has been executed by Mr. John Palsford, of Barnstaple, and the builder's work by Mr. Jessie Chessum, of Shoreditch, from the designs and under the superintendence of Mr. D. Alexander Lander, architect, of London and Barnstaple. The cost of the alterations has been about £700.

CHIPS.

At a meeting held at Eastbourne on Saturday it was resolved to endeavour to raise £4,000 in subscriptions for a cottage hospital, "as a memorial of the late Princess Alice."

Another stage has been reached in the artisans' dwellings scheme at Dublin, the award of Mr. Posnett upon the claims for compensation in respect of the unhealthy area in the Liberties to be cleared for this purpose, having been lodged. The gross sum awarded is greatly in excess of the estimate of the committee of the Dublin corporation and its officials.

At the Easter vestry held at Charlecombe last week a vote of thanks was passed to Mr. J. B. Wilson, of Bath, for his gratuitous services as architect during the improvement and restoration of the church, now almost completed. At the same meeting a new font cover was promised to be added to the church furniture.

The commemoration stone of the parish church of St. George, Gloucestershire, was laid on Wednesday week by the Mayor of Bristol. The fine old parish church, which was completely restored in 1876, was destroyed by fire at Christmas last. It is now being rebuilt from the plans of Mr. P. E. Massey, architect, of London. The estimated cost is £6,000.

Mr. Eli Johnson, a pupil of Mr. Boehm, is engaged on a bust of Dr. Moffat.

The Local Government Board inquiry on the Newmarket sewerage scheme, for which the local board of that town seek to borrow £5,000, was concluded by Mr. S. J. Smith, C.E., inspector, on Saturday, when Mr. J. F. Clark, the engineer of the scheme, explained his plans and the proposed utilisation of the sewage on the land.

According to a daily contemporary, Exeter Hall is likely ere long to exist only in the memory of attendants at May meetings and frequenters of monster concerts and great political gatherings. Negotiations have been in progress for the acquisition of the site for a great theatre, and these have been chiefly impeded by the onerous condition of rebuilding the adjacent houses, a large new hotel being part of the scheme. The hall was built from the designs of Mr. Dering about fifty years ago. It would be missed, for London is but ill-provided with convenient places for great gatherings. It is not, however, the most scientifically constructed of London buildings, and its facilities for allowing the rapid egress of a crowded audience in case of a panic would hardly be approved of in these days by the surveyor of the Lord Chamberlain's office if a theatrical licence were applied for.

An Elizabethan door in a cottage near Hoo, at Minister-in-Thunet, which has been illustrated in Vol. XII. of the Kent Archaeological Society's *Journal*, has been sent to Bifrons by order of the Marquis of Conyngham, the cottage having been pulled down.

The Town Council of Derby held a special meeting on Monday, at which it was decided to carry out a scheme under the Artisans' Dwellings Improvement Act, 1875, in three parts. By this plan it is proposed to remove blocks of dilapidated houses in the neighbourhood of Willow-row, Goodwin-street, and Wright-street, and to replace them by new and habitable structures. The total cost of the undertaking is estimated at £86,000, at twenty years' purchase of the properties.

The construction of drainage works was commenced in the town of Briton Ferry on Monday. Messrs. Hill Brothers, of West-town, near Bristol, are the contractors.

Our Office Table.

The following information in regard to the great value of the ailanthus as timber, is taken from a paper on the subject by Prof. C. S. Sargent:—In experiments made in the French dockyard at Toulon, where the wood of this tree was tested as to its tenacity, or ability to resist a strain, in comparison with the timber of European elm and oak, an average of seven trials showed that the ailanthus broke with a weight of 72,186 pounds, while the elm in a similar number of trials yielded to 54,707 pounds, and the oak, in the average of ten specimens, broke under a weight of 43,434 pounds. Evidence as to the value of ailanthus timber in exposed situations and as to its durability when set in the ground is yet meagre, but the little that we have is favourable. Of its value for interior work and for cabinetmaking there can be no doubt, the wood possessing properties remarkable in so rapid-growing a tree. The wood is at first of a pale straw-colour, but grows somewhat darker with age, and takes a high polish. When cut to show the silver grain it presents a satiny lustre, and as regards freedom from warping and shrinking it is superior to walnut and fully equal to mahogany. It is said to cut up economically, seasons readily, is easily worked, is free from unpleasant odour, and has no ill effects on the tools. For the treads of stairs, the floors of offices, mills, and other buildings, where constant use requires a hard, strong wood, it is probably superior to any of the woods commonly employed in such situations. There is one use for which its freedom from tendency to shrink will especially commend it—i.e., interior finishings. Its warm colour will make it very effective, when used with both lighter and darker woods.

An important link is about to be added to the Midland and Northern railway system by the opening of the line just completed between Swinton and Ferrybridge. The line which will be formally opened for passenger traffic on the 2nd of June will run from the North-Eastern line at Ferrybridge, near to Knottingly Station, joining the Midland system about one mile from Swinton, on the main line north and south, and by the opening of this connection a clear saving of some thirteen miles will be effected in the journey from York to London, as the passenger will travel this way instead of *via* Normanston, Sheffield, and all the towns in the Midland counties too will also be placed in easy communication with York, Newcastle, and the Scotch trains by means of the joint lines. The contract for the making of the line was let in the autumn of 1875 to Messrs. Dransfield and Co., of Liverpool, the first sod having been cut on the 8th of September of that year. The consulting engineer was Mr. T. Harrison, C.E., London, the resident engineer being Mr. Francis Liddell, under whose superintendence the works have been carried out. The total of Messrs. Dransfield's contract will be about £450,000. The line is a little over fifteen miles in length.

INQUIRIES are made from time to time for the best methods of rendering pencil drawings ineffaceable. The *Papier Zeitung* recommends that the paper be prepared in the following manner:—Slightly warm a sheet of ordinary drawing-paper, then place it carefully on the surface of a solution of white resin in alcohol, leaving it there long enough to become thoroughly moistened. Afterwards dry it in a current of warm air. Paper prepared in this way has a very smooth surface. In order to fix the drawing, the paper is to be simply warmed for a few moments. This process may prove useful for the preservation of plans or designs, when the want of time will not allow of the draughtsman reproducing them in ink. A simpler method than the above, however, is to brush over the back of the paper containing the charcoal or pencil sketch with a weak solution of white shellac in alcohol.

PROFESSOR DOREMUS, of the Buffalo Medical College (New York), recently performed an interesting and instructive experiment before his class. A block of sandstone such as is usually employed for window caps and sills, and about twelve inches square and four or five inches thick, had a panel one half an inch deep sunk in each side. In each panel was fitted a block, which was perforated by a piece of common gas-pipe, and this was cemented about the edges. The whole was then coated with an impervious varnish.

Air now entering the pipe on either side had access to the clean surface of the stone beneath the panel, and it was found that if the mouth be applied to the protruding pipe on one side, and a candle be placed in front of the opposite one, it could very readily be blown out by the air, which, with very little effort, was forced through the stone. When a rubber tube was connected with the house gas-pipe on one side of the stone, and a burner was attached on the opposite side, the simple pressure from the gas mains was sufficient to force the gas through the stone till it was lighted at the burner on the opposite side. When by any means the pressure was increased, a very large flame was thus produced. This shows the permeability of building stone. Brick walls and the plastering of rooms are much more porous, and it may be readily seen that unglazed tile, or stone, or brick sewers afford but little security against the escape of sewer gas.

MR. EDWARD CHALLINOR, the oldest earthenware manufacturer of the Staffordshire Potteries, died on the 16th inst., in his eighty-seventh year. Born at Leek, and a son of Mr. William Challinor, a solicitor of the town, he went at an early age as an apprentice to the manufactory of the late Mr. Riley, of Burslem. After his apprenticeship he commenced business himself in 1819 at the earthenware works formerly belonging to Mr. Wood, at the Overhouse, Burslem. These works he subsequently purchased, and in 1839 erected on the site the present manufactory, where Mr. Ralph Hammersley carries on business. Subsequently, having dissolved partnership with Mr. Wood about the year 1841, he built a new earthenware manufactory at Tunstall, being the one now occupied by Mr. Enoch Wedgwood. Here he carried on business until about the year 1863, when he retired temporarily from trade. In less than a year, however, he commenced again at the small works in Tunstall, now occupied by Mr. Ralph Hammersley, where he continued as a manufacturer until about 1873, when, being upwards of eighty years of age he finally retired from business.

At the last meeting of the board of the National Gallery of Ireland a letter was read from Sir Richard Wallace, Bart., M.P., who has lately become a member of the board, offering an interesting picture by Salvator (a portrait of Guercino, the painter), for presentation to the gallery. The director of the gallery, Mr. Doyle, was requested to accept the gift with thanks. Among the principal donations of works of art received for and placed in the gallery during the past year are, a marble statue of Apollo, by F. M. Poncet, a French sculptor of the last century, formerly the chief ornament of the ball-room of Leinster House, from the Duke of Leinster; a "Seapiepe," by Abraham Storck, next to the younger Van de Velde, perhaps the best marine painter of the Dutch school, from the Earl of Portarlington; "St. Cecilia with the Angels," one of the works of Carlo Cignani; "Lucretia," by Elizabeth Serrani, and a portrait of the time of Charles II., said to represent the Duchess of Portsmouth, by Nicholas Maas, all three from Sir Henry Barron, Bart.; and a large portrait group of the Ely family, by Angelica Kauffman, from the Marquis of Ely.

THE new collection of oil and water-colour paintings exhibited in the picture gallery at the Crystal Palace is, on the whole, a better one than that of 1878. The foreign exhibitors still, however, contribute a majority of the more noteworthy pieces. The hanging of the pictures has been accomplished under the direction of Mr. C. Wass. On Wednesday Mr. W. B. Frith, R.A., Mr. J. C. Horsley, R.A., and Mr. G. H. Boughton, acting as judges, awarded the medals offered to exhibitors by the Crystal Palace company. The awards included six gold medals, valued at 25 guineas each, twenty silver medals, valued at 6 guineas, and fifteen bronze medals, valued at 3 guineas. In the competition the works of English artists were divided into three classes:—A, History or figure subjects in oil; B, Landscapes, sea-pieces, animals, and other subjects; C, water-colour drawing, irrespective of subject. In class A, Mr. E. R. Taylor gained the gold medal for "The Cloister Well," the silver medals going to Mr. A. Stocks, Mr. J. C. Waite, Mr. J. Hayllar, and Mr. E. G. Girardot, and the bronze medals to Miss E. Conolly, "Covenanters on their way to Prison," Mr. Haynes King, and Mr. J. Morgan. In Class B, the gold medal was awarded to Mr. A. L. Vernon for a country

idyll, the silver medals to Mr. D. Cameron, Mr. Y. King, Mr. H. Caffieri, and Mr. F. W. Meyer; and the bronze medals to Mr. R. Gallon, Mr. J. Peel, and Mr. L. C. Nightingale. In Class C, Mr. W. Hall's "Ullswater Lake—Moonlight" brought him the gold medal, the silver medals being gained by Mr. Henry Moore, Mr. D. Law, Mr. Hughson Hawley, and Mr. L. L. Pocock; and the bronze by Mr. T. C. Dibdin, Mr. R. Rasell, and Mr. E. Hargitt. The special gold medal open to the competition of artists and collectors for the best picture exhibited, without regard to school, style, or subject, was gained by Mr. T. Davidson, for his "Dowsabell." The works of foreign artists were also considered in two classes. In class D—for History or Figure Subjects in Oil—the gold medal was given to Mr. B. Nordenburg for the "Marriage in a Swedish Village Church;" the silver medals went to Mr. Charles Frere for his group of wheelwrights "Firing the Wheel;" Mr. H. Sondernmann, Mr. L. Vollmar, and Mr. C. Kronberger, and the bronze to Mr. T. Cederstrom, Mr. J. A. Neuhuys and Mr. G. Meyer. The gold medal in Class E—landscapes, sea pieces, animals, &c., was adjudged to Mr. C. Kroner; the silver medals were awarded to Messrs. J. Bauck, V. St. Lesche, H. Baisch, and E. Weichberger, and the bronze to Messrs. O. Jernberg, H. Dieters, and F. Heimerdinger.

CHUBB'S

WROUGHT IRON DOORS,

Fire and Thief-Resisting Strong Rooms, Safes, and Iron Linings.

THREE PRIZE MEDALS

And Honorable Mention at PARIS EXHIBITION, 1878.
Illustrated Price Lists post-free.

CHUBB & SON, Makers to the Bank of England,
128, Queen Victoria-street, St. Paul's, E.C.; and
68, St. James's-street, Pall Mall, London.—[Ave.]

CHIPS.

A new Baptist chapel was opened last week at Westbourne, near Bournemouth. It is Gothic in style, and measures 40ft. by 20ft.; it is built of brick, with stone corbels, and a roof of open timber, varnished. Attached is a schoolroom 20ft. by 15ft. The architects were Messrs. Burton and Stephens, and the builder was Mr. M. Carpenter, all of Bournemouth. The cost has been about £850.

At the last Commencement of Washington and Lee University of Virginia, the diploma of LL.D. was *honoris causa* conferred on Mr. Beresford-Hope, M.P. This diploma was, on Tuesday, presented to Mr. Beresford-Hope at his residence, Connaught-place, Hyde-park, by a deputation from the Rector, President, Faculty, and Trustees of the University.

The Committee appointed to carry out the extension of the Burial Ground attached to the parish church of Southwick have accepted, out of several competitors, the tender of Mr. Charles Curd, builder, of New Shoreham, for building the enclosure boundary walls, &c., for the new ground, and the work has commenced and is being carried out from the plans of Mr. Arthur Loader, architect and surveyor, of Brighton and Shoreham.

The office hours for all clerks in the Queensland public service have been extended from four o'clock to six o'clock in the afternoon.

At a meeting of the creditors of William Wainwright Williams, brick manufacturer, of Bordesley-green, Birmingham, held on Monday, the debts were shown to be £4,236, and the assets £105. A composition of 1s. in the pound was accepted.

A stained-glass window has been placed in the east-end of the south aisle of the chancel of St. Giles's Church, Reading, by the present Mayor of the town, in commemoration of his silver wedding.

The Brougham centenary festival at Cannes was closed by the unveiling of a marble statue, which occupies a site facing the sea, and near the Town Hall.

The memorial to Bishop Heber in the church of Malpas, in which parish he was born, will probably take the form of a stained-glass window.

Mr. George Baker, of Great Yarmouth, has been presented with an electro-plated tea and coffee service, in recognition of his honorary services as architect for the new Primitive Methodist Chapel at Halvergate, Norfolk.

Last Friday a new Masonic Hall, which has just been erected at Ipswich, was opened. The new buildings are built of red brick from the designs of Mr. H. Luff, and have been erected in about four months by Messrs. E. and C. E. Gibbons.

A new Board School in Stinchley-street, Birmingham, was opened on Saturday. The school has been erected by Mr. Walter Brooks, Sheepcote-street, Birmingham, from the design of Mr. W. Hale, architect, Colmore Row, Birmingham. It is built of ordinary brick, in a simple Gothic style, the woodwork being of stained deal. The total amount of the contract was £1,893.

The Monument on Fish-street Hill, London, is at present undergoing several repairs. Among other things, the top of the monument, which was designed to represent a flame, is to be regilded. The work is being done by direction of the Corporation, and it is stated the cost will exceed £500.

Some school trustees confuse the duties of architect and teacher, if an American paper is to be trusted. One recently visiting a school remarked: "Well, Mr. Syntax, you have a very fair school here." Mr. S. "Yes, sir, the school's well enough, but the curriculum is defective." New Trustee. "What, the curriculum defective? We must see the architect at once about it, and have it raised a few feet higher."

Six tenders have been received for the restoration of the nave and muniment room of Bangor Cathedral, but all being much above the estimate, the plans of the late Sir Gilbert Scott will, it is said, probably be modified.

On Easter Monday afternoon the memorial stone of a new Wesleyan chapel at Haxby was laid. The new building will provide sitting accommodation for about 300 worshippers, and Sunday school room for 100 children. The total cost will be about £1,200. The architect is Mr. E. Taylor, of Stonegate.

On Easter Sunday a new Wesleyan chapel at Cottingham was opened. Mr. C. H. Payne, of Kettering, was the architect. The style is Classic. The principal elevations of the building are faced with Harborough pressed brick. The contract was taken by Mr. Crisp, of Harborough, at £423.

The present restoration of the Priory Church, Bridlington, having been brought to a conclusion, the event was celebrated on Thursday week. The Archbishop of York, who preached, said that a former restoration had cost £10,000, the present one £17,000. The restorations are from the designs of the late Sir Gilbert Scott, who took a special interest in the work, which has been continued since his death by his sons, Messrs. G. G. and J. O. Scott. Mr. J. Thompson, of Peterborough, has been the sole contractor, and has executed the work under the superintendence of Mr. J. Wills, the clerk of the works.

A new Cottage Hospital is being built at Maidenhead by Mr. W. Woodbridge, from the designs (gratuitously supplied) of Messrs. Henry Cooper and Son, architects, 86, High-street, Maidenhead. The materials used are red and grey bricks, with Bath stone lintels and sills; the roof to be covered with Broseley tiles. The buildings are intended to accommodate four male and four female patients, and are all on the ground floor. The contract is £1,350.

The foundation stone of a new Oddfellows' Hall, at Launceston, was laid on Easter Monday. The building will comprise a hall, 45ft. by 25ft., lobby, lavatory, ante-room, &c., with rooms underneath for a curator to reside in. The style is to be Romanesque. The steps and plinth will be of granite, and the walls of the best red bricks, with Portland stone dressings. The plans were prepared by Mr. C. P. Wise, architect, of Launceston, and the building is to be erected by Mr. Wm. Burt, contractor, of the same town.

We are glad to hear of the recovery of Mr. C. J. Phipps, who was seized with a sharp attack of congestion of the lungs recently, while in Aberdeen.

Plans have been prepared by Mr. F. Chancellor, of London and Chelmsford, for the restoration of the parish church of Writtle, Essex. The estimated cost is £1,100.

A new bridge erected over the Sutton-drain, at St. Mark's-street, Hull, was opened on Wednesday week. It has been tested to 50 tons, and supersedes a narrow brick arch, built by the late George Liddell. The platform is supported on nine wrought-iron plate girders, each 3ft. apart, and from 1ft. 7in. to 2ft. deep, and on two outside bit girders of like depth under the parapets. The former are covered with buckled plates, and the latter support curved plates, which extend from plate girders, and carry the footways. A layer of concrete is spread over these plates, on which is laid the flagging and wood pavement. The parapets are formed of cast-iron latticed panels, fixed between newels, and terminated by Bramley Fall stone pedestals built on the abutments, which are of white brick. The estimated cost of the bridge was £2,500, and it has been completed for £2,593. It is the fourth bridge constructed during the past five years from the designs of Mr. J. Fox Sharp, the borough engineer. Mr. Malono was the contractor.

The annual meeting of the Association of Sanitary Inspectors of Essex and neighbouring counties was held at Chelmsford, on Thursday, the 17th inst., Mr. A. F. Ginn, of Chelmsford, in the chair. Discussions took place on a paper read by Mr. Bell, of Epping, relating to hospital accommodation for infectious diseases, and on the Public Health Amendment (Water) Act, introduced by Mr. Boulter, of Halstead. Mr. F. Godfrey, of Braintree, was appointed president for the ensuing year, and Mr. Hamilton, secretary.

Steps are being taken to complete the restoration of the parish church of Burnham, Somerset. The work proposed includes the repewing and repairing of the north aisle, and the removal of the present unsightly gallery.

The parish church of Ulceby is to be re-opened on the 29th inst., after the restoration of the south aisle, and the erection of a south porch.

A new reredos has been placed in the parish church of St. Mary, Chelmsford, in memory of the late Archdeacon Mildmay. It consists of an oak frame carved in the Perpendicular style. In this are three panels, each occupied by an oil painting executed by Miss Mildmay, from Italian works; that in the centre represents the Crucifixion. A parclose of carved oak, also in the Perpendicular style, has been placed on the north side of the chancel, and a similar screen is to be placed on the south side.

The first exhibition of the Woodford Industrial and Art Society was held on Tuesday and Wednesday in last week, and proved so successful that it is proposed to make it an annual institution. The exhibition, which originated with Mr. S. J. Taylor, was divided into three sections: 1st. Works of art, containing 29 classes; 2nd. Industrial work by women, containing 21 classes; and 3rd., works of children, containing 15 classes. Besides these a good loan collection was contributed by friends.

A Local Government Board inquiry was held at Southend-on-Sea, on the 17th inst., before Mr. Harrison, C.E., respecting an application from the local board, for permission to borrow £1,000 for new works of sewerage in Porter's Town, Milton-street. The plans have been prepared by Mr. R. B. Harrington, the surveyor to the board. It was stated that the board had already borrowed £12,400, and that further sums of £1,100 for the Hamlet Valley sewerage, and of £1,000 for the eastern esplanade scheme would shortly be required.

Mr. John James has been appointed bridge surveyor for the town and county of Haverfordwest, South Wales.

In celebration of the completion of a new wing to the hospital, at Mereton-in-the-Marsh, the workmen were entertained at supper on Monday week. Mr. Calloway is the architect, and Mr. Gill, the contractor.

The foundation stone of a new Wesleyan church was laid in Bath-road, Swindon, on Wednesday week. The chapel is being erected by Mr. T. Barrett, who has taken the contract at £4,891 ss. 6d.

At Beccles, Suffolk, on Monday, the 14th inst., the foundation stone of a new Congregational Sunday School buildings was laid. The architect is Mr. Edward Bondman, of Norwich, and the scheme includes a principal building seating 300 adults, and 8 class-rooms.

The Town Council of Colchester unanimously decided at a meeting held on Saturday week, to purchase the waterworks from the private company in which they are now vested.

The Wesleyan chapel, at Belper Pottery, has been reseated and refloored; the contract has been executed by Messrs. Wheeldon Brothers, of Belper. A new schoolroom, 48ft. by 21ft., with class-room beneath, has been erected for the same Wesleyan community, by Mr. Loomes, contractor of Belper, and both chapel and schoolroom were opened for services on Easter Sunday.

The Duke of Westminster and Sir Robert Cunliffe visited the sewage farm of Col. Jones, V.C., at Hafodywern, near Wrexham, last week, in order to see in operation the sewerage ejector, invented by Mr. Shone.

A cocoa-house was opened last week, at Rhoslanerchrnog. The alterations have been carried out by Messrs. Jenkins and Jones, builders, of Johnstone, Raibon, and the decorations by Mr. Coplestown, of Wrexham.

The foundation stone of a new Congregational church was laid at Sawston, near Cambridge, on Easter Monday. The church will be Gothic in style, will measure 74ft. by 37ft., and is estimated to cost about £1,500. The architect is Mr. J. Sulman, of London, and the builder Mr. Garwood, of Haverhill.

A new Roman Catholic church, dedicated to St. Patrick, is about to be built at Walton-le-Dale, from designs by Mr. Pugin.

THE BUILDING NEWS.

LONDON, FRIDAY, MAY 2, 1879.

ARCHITECTURE AT THE ROYAL ACADEMY.

FIRST NOTICE.

TO-DAY the private view at the Royal Academy is being held, and deference to the general rule precludes our noticing the works in detail, even if we had time this week to write at length about them. It may, however, be interesting to say a few words generally about the Exhibition, and certainly, at the outset it cannot fail to be observed how very few architectural drawings are this year exhibited. Out of the fifteen hundred and eighty-six exhibits at the Royal Academy only one hundred and fifteen have been selected to represent architecture, a selection hardly equal to two-thirds of the number generally allotted to what Mr. Street called, the other evening, at the Institute Dinner, the "Mother of the Fine Arts." Surely the secondary Arts have ousted their mother, judging from the small collection of drawings permitted this year to represent the "parent art of architecture." And especially is this the case when the comparatively large number of decorative, competition and ideal designs are taken into consideration; for these are this year unusually numerous. The merit of the works shown is, no doubt, as a whole, of an average order, though several representative names are absent from the Exhibition altogether. It seems from the experience of the past that architecture must inevitably take a very second-rate place at the Royal Academy, and, indeed, in the annual exhibition at Burlington House; from the nature of the case probably this must always be so, but we see no reason why the few drawings of architectural works which are exhibited should not illustrate as far as possible the best and most important examples executed during the year. It is true that the past year has by no means been a prosperous one for architects, and their buildings have perhaps been few, but, on the other hand, the rejected drawings from the Royal Academy Exhibition have been very much more numerous on this occasion than ever before, including several works of a high order, and by well-known men. If it be intended to raise the standard of merit in selecting works for the Exhibition no one can complain, but evidently this has not been the case, while, as we have already said, the decorative and ideal designs are by far too numerous in so small a collection. Mr. G. E. Street, R.A., is well represented by no less than six works, four of which are churches, viz., St. Mary's Church, Monmouth; Holmbury St. Mary, Surrey; the parish church of St. Peter, Bournemouth, showing the spire; and the new church of St. Mary, Speenhamland, Berks. All of these are characteristic of the author's work, full of pure and good detail, and evincing the master's hand. The remaining two drawings will, however, attract the most attention, and deservedly so, as they illustrate one of Mr. Street's earliest domestic works and one of his very latest. They do not in themselves present any leading points for comparison, the buildings being so different in size and intention. The former drawing is a large bird's-eye view of St. Margaret's Convent, Chapel and Schools at East Grinstead (1143); the latter shows mansions about to be erected on the Hans-place estate in Cadogan-square (1174). All the drawings are by Mr. Street himself in his peculiar manner, though perhaps less careful than

usual; but then the wonder is that the author should have found the time to make the drawings at all. We shall return, of course, to these works later on. Mr. Norman Shaw, R.A., has only one drawing this year. It is his diploma picture of Adeote, Shropshire, a work already known to our readers by the illustration given by us just after it was made, in the Christmas number of the BUILDING NEWS last year.* Mr. Shaw could not have chosen a better subject for his diploma work as it illustrates him in that particular phase of Late Gothic, which he had made his own before he lent his hand to the more debased style known as Queen Anne, and considering the lengths to which this last named style have been already carried, Mr. Shaw's truest admirers must certainly desire that he should return to the Gothic work, such as that so charmingly illustrated by Adeote, Shropshire. Even in the present exhibition at Burlington House, where so-called Queen Anne is conspicuously absent, it is refreshing to turn to Mr. Shaw's lone work at the end of the room. Mr. Alfred Waterhouse, A.R.A., has three water-colour drawings, illustrating the Prudential Offices, in Holborn; the New Court Chambers Quad in Lincoln's Inn, and Pembroke College, Cambridge; this last being to our mind the best work of the three as an example of architectural design. Neither Mr. Pearson nor Mr. E. M. Barry send any works, and we miss the drawings of Messrs. W. Burges, Bodley, Gibson, Talbert, and Seddon. Turning to the catalogue Mr. Ewan Christian heads the list, with rather a commonplace though quiet house in Sussex, called Glyndebourne, and immediately below Mr. J. J. Stevenson has rather a striking subject in Ken Hill, Norfolk, shown by a singularly poor water-colour drawing. The house is in stone, treated in "Free Classic," picturesque enough and quaint, but not very like a gentleman's house. Denton Hall, Grantham, by Mr. Arthur Blomfield, M.A., is a more satisfactory and extensive work, though perhaps a little broken up. The drawing is exceptionally cleverly executed in pen-and-ink. The School Board and Municipal Offices (1,080 and 1,114), at Leeds, by Mr. Corson, are shown by very coarse pen drawings, which are deservedly hung rather out of sight; and here we may say, with reference to the hanging, that the pictures are well balanced in the massing on the walls, and with few exceptions have been judiciously appropriated; but why the place of honour in the centre of the long side of the room should have been given to 1,144, a student's aerobatic design for a provincial town hall, by Mr. W. Scott, in which almost all the styles of Gothic have been introduced, we cannot conceive; neither can we understand why the hot and heavily-tinted drawing (1,145) just over the last-named should have been hung where it is, crushing rather than crowning all the adjacent drawings. It represents, too, a very overdone interior, with decorations and furniture in a rather used-up style. Mr. W. Hensman is the author. Messrs. Dunn and Hansom have a neatly-finished view of Downside Monastery and College (1,081); and Mr. E. F. C. Clarke sends a boldly-drawn, if crudely-designed, alteration to the ugly old church of St. Mary at Woolwich (1,082). Skipness is a Scotch house in Argyllshire, by Mr. John Honeyman, which, from the small, quiet view, might be overlooked; it is an unusually good and artistically correct rendering of a much-abused and misunderstood style. Passing a pleasing view by Messrs. Herbert Carpenter and Ingelow, of Knowle House, Wilts, we come to two of the series of four drawings by Messrs. Ernest George and Peto—viz., the "Coffee-house, at Streatham," and "Barrow Point, at Pinner" (Nos. 1,026 and

1,087), the others being "Some Almshouses at Guildford" (1,140) and (1,149) "Some Cottages at Pinner." Of these we may say that all are exceptionally piquant examples of that simple domestic style in which Mr. Ernest George has hitherto practised with so much taste and appropriate feeling, and of the class to which they belong are second to none in the Exhibition. Mr. Eldon Deane's wild and singular design for a convalescent hospital is not badly drawn, but seems out of place in the show, and so does 1,072, a small, uninteresting house at Godalming, by Mr. Ralph Nevill; indeed, we only name it as an example of what should not have been exhibited. Mr. T. E. Coleutt's work is always good, and thus the three lodges at Easton Park (1,093) are in every way suitably treated in half-timber, without fuss or finery. 1,138 shows some stone houses at Nightingale-lane, Wandsworth, by the same artist, though we like these less than the first-named. The interior of Mr. Coleutt's Paris house, 1,176, is very good, excepting the soffit of the staircase, which seems rather heavy.

Mr. Isaac Barradale has some good houses at Leicester, and Messrs. Dodgshun and Unsworth a skilful residence in half-timber, at Shepherd's Spring, Hants. Their staircase from the Stratford Memorial Theatre is less happy. Mr. R. W. Edis has a red brick new house at Eastbourne, shown by a not very pleasing water-colour view, but his principal exhibit is a large pen-and-ink drawing, by Mr. Maurice B. Adams, of the conspicuous new building in Bond-street, at the end of Conduit-street, a work of considerable merit, to which we shall again recur. Of the several designs exhibited of the new Oratory Church at Brompton, the selected design (No. 1,099) deserves to be first named, and, indeed, it has the chief place in the end of the room fronting the entrance. We have this week reproduced Mr. Gribble's drawings, so that our readers may study the work in detail. The interior is the only drawing of this design exhibited, and we regret the unpleasant colouring of the picture, which in other respects is clever, and having an effect of vastness about it not found in the interiors of the other designs which have been selected for exhibition. These include two drawings by Messrs. G. G. Scott, M.A. (1,100, 1,122), A. J. Adams (1,157); Geo. Nattress (1,097), and 1,110 by Messrs. Goldie and Child. To these we shall refer again, and also to Mr. Emerson's beautiful drawings (1,113) of the Tukhtsingji Hospital at Bhavnagar, India, and (1,172) St. Mary's Church, Brighton, showing the tower and spire. No. 1,103 is Mr. Gilbert Redgrave's interesting house from the Paris Exhibition, rather, perhaps, too ornate for a typical example of English half-timber. It is worthy of exhibition here from the importance of the subject; but we fail to gather why the design of Cocoa House, Festiniog (1,106), should have been awarded so conspicuous a place; and certainly Mr. Samuel How's design for a hall (1,109) is utterly below ordinary merit, yet it has a very good place. Mr. Ernest C. Lee just over the last-named has his cottages at Midhurst, in every way good, but, notwithstanding, it is one of last year's rejected drawings. His other accepted work this year is one of the most interesting in the room; we published it the week before last, No. 1,182, "The New Bank at Colchester," nicely drawn by Mr. Gregg. Mr. John O. Scott has but one drawing, it is by Mr. W. Weatherley, of "The Tower of St. Paul's Church, Manchester" (1,112); and Mr. Basil Champneys exhibits close by (1,117) a not very good drawing in brown ink of his "New Divinity Schools at Cambridge," in Late Gothic, treated in a free and masterly way, far beyond any other new work of the kind in Cambridge that we have seen; the drawing, however, does it spare justice. Mr. T. H. Wyatt has a view (1,120) of his "Hospi-

tal for Consumption at Brompton," in a sort of Free Classic in red brick and stone, boldly and simply treated. Here we reach an inky drawing of a design for "The Consumptive Hospital at Hampstead" (1,125), by Mr. W. Tasker, occupying a large space without any apparent reason whatever. "The Grange at Ramsgate," by Mr. Pugin, would be of interest if we could only see it, but at present it is skyed. Mr. T. G. Jackson exhibits one of the most charming interiors in the way of woodwork and colour, that we have lately seen; we refer to 1,126. St. David's College Chapel, Lampeter, a study in late Gothic in green. His other drawing is a sepia view (1,161) of the proposed buildings at Merton College, Oxford, a work not equal to his Examination Schools in the same town. Mr. James Brooks has but one drawing, a nice pen-and-ink interior of St. Modoc Scotland (1,129). Of old work here, we may just name one or two examples in passing as of special merit. (1,098) The Giant's Staircase, at Venice, by John Bunney, a fine drawing in colour; (1,121) by Mr. Charles H. Rew, in pen-and-ink, of the Market Hall, Malines, not Meehlin, as in the catalogue; and the Church of St. Père sous Vézelay, France, by Mr. P. J. Marvin, next to which is an interesting sketch by Mr. J. Twigg, of the Hotel de Ville, Beaugency. By a very red drawing, Mr. Phené Spiers does not flatter his mansion on the Thames Embankment, at Chelsea, a work in Queen Anne of much refinement and character. (1,163) Carlyle House, Chelsea, by W. Adolphus Croft, is hard by, and so claims notice here as a similar work. Mr. E. R. Robson for once has forsaken "Queen Anne" in his Town-hall at Loftus-in-Cleveland (1,152), a simple Gothic building, beautifully drawn by Mr. W. Rushworth. The Grange (1,159), by Mr. J. D. Sedding, seems rather the study of an old work. The Church of Our Lady with Priory, at Marychurch (1,166), by Messrs. J. A. Hansou and Son, is an important work, and (1,173) The Consumption Hospital, at Hampstead, by Mr. T. Roger Smith, deserves notice, and so does Mr. J. Langham's Country House (1,168). As for 1,169, 1,179, and 1,183, the less said the better; they should never have been hung if good work alone is to be exhibited. We have only one more drawing here to mention (1,178). It is Mr. G. G. Scott's design for the new front, or rather alterations to the front of Mr. Haweis' church, St. James, Westmoreland-place. There is much that is novel in Mr. Scott's proposal, and we are not favourably impressed with his design, however ingenious the arrangement of the bells may be in the series of arched openings at the top of the façade on either side and over the clock, where there is a sort of bell turret arrangement. There may, however, be some occult reason for the treatment adopted, as we know that Mr. Haweis is an authority on bells.

Next week we shall notice at greater length both the architectural drawings and the pictures.

THE GROSVENOR GALLERY.

THE exhibition of paintings at the Grosvenor Gallery this year, if it does not surpass, at any rate equals former displays. The present collection affords a varied bill of fare, in which composition, portraiture and genre hold conspicuous places. In the large gallery several important works are to be seen upon the walls, including pictures by Sir F. Leighton, P.R.A., W. B. Richmond, Carl Haag, E. Matthew Hale, H. Herkomer, T. Armstrong, Walter Crane, J. M. Strudwick, P. R. Morris, A.R.A., J. E. Millais, R.A., R. Lehmann, R. Smallfield, A. Legros, G. F. Watts, R.A., J. D. Linton, J. Tissot, J. M. Whistler, and other well-known painters. Mr. W. B. Richmond con-

tributes a few remarkable portraits and studies. We must place his "Sitting in Judgment" (5), "A Study of Light and Shade" (9), and "The End of the Story" in the highest rank for careful colouring and execution. "Sitting in Judgment" has a touch of humour; it is a portrait of a little girl seated in a dark arm-chair with an air of judicial calmness and child-like simplicity. The black dress and dark sombre drapery behind enhance the solemnity of mien with which the child is invested. A "Study of Light and Shade" is certainly clever in the shadow cast by the brim of hat over the face of the young girl, and the face is transparently painted. The portrait of Miss Ada White Thompson is a dreamy face; the eyes are languid and expressive, but the fingers of the hand are evidently too long. More pleasing is "The End of the Story"; a girl seated upon a table has closed her book, and reposes in a pensive mood. Mr. Carl Haag sends two highly finished water-colour heads, one a "Nubian Warrior," admirable in drawing and the finish of the chain armour, and another "An African Beauty." We cannot praise Mr. A. Stuart-Wortley's "Moonlight View of Charing-cross Bridge," it is badly drawn, to say the least, and we have seen better pictures from him. Mr. E. Matthew Hale in "Psyche's Toil in Venus's Garden" (17) has been inspired by a passage in the Story of Cupid and Psyche in Morris's "Earthly Paradise," where Psyche labours in sorting the seeds in Venus's garden. The picture has undoubtedly poetical sentiment in its composition, the figures of the damsels are graceful, and the colours of drapery harmonious, though rather tawdry. The dark background of trimmed hedges of the garden, and the blue pavement, make up a large canvas, somewhat crude and sensational.

Mr. Cecil Lawson's "Kent" (19) is a large picture of a landscape, with a plantation of hops in the foreground, but it is evident the poetic allusion intended to be conveyed of the "jovialman of Kent, as through his golden hops he went," has been lost in the surroundings. It is simply a landscape, with a vast deal of labour thrown away upon it. For composition and sentiment, Mr. W. G. Will's contributions, "Ophelia and Laertes," and "The Spirit of the Shell" (20 and 21), stand high; the latter is a clever, poetical idea, painted with considerable power. Mr. W. B. Richmond has painted a fabulous conceit, called "Sarpedon," but the idealisation is disappointing, in spite of considerable power and careful painting. Perhaps one of the most remarkable, because natural, pictures, no less wonderful for its execution than for the sentiment introduced, is Mr. Herkomer's "Light, Life, and Melody" (24). It is painted in pure water-colours, though it has all the solidity of oil, and, we believe, is partly intended as an experiment to test the capability of the former vehicle. The scene represents Bavarian peasants seated in a Kegelbahn, listening to the strains of a zither being played by a hunter. Behind the player is the standing figure of a girl, moved by the melody, while peasants are seated round, listening and conversing together. Beyond, in the distance, are seen blue hills. In conception, Mr. Herkomer has seized upon a subject that brings into full play his marvellous aptitude for character portrayal. The old men conversing are yet enthralled by the music, and the artist has produced every effect but the sound necessary to the realisation of the scene before us. The figures are relieved by sharp lights scratched from the paper, the tanned countenances of the old men and the reflected light on their faces are realistic, though broadly handled. Several sheets of paper were necessary, we are told, to produce so large a picture, and these have been joined in the lines of contour of the figures. The same painter has sent a life-size

portrait of Alfred Tennyson (49), in which the poet-laureate is shown dressed in a cloak. The execution has all the depth of oil and dark background, setting off the fine head and flowing hair. His other contributions in water-colour are of minor interest. "Auf der Alm" (251) is forcible in colour and the drawing of the mountain peaks. A few spirited etchings are also exhibited in the sculpture gallery. In decorative or ideal subjects the present exhibition is full of interest, if we cannot say excellence. Mr. T. Armstrong, Mr. Walter Crane, and Mr. E. Burne Jones this year carry off the palm. Mr. T. Armstrong's "Fountain" (27) is graceful in conception; the colouring is harmonious and refined, and the painter has wisely selected tints of a low scale. We cannot say we are much entranced by Mr. Walter Crane's piece of "The Sirens" (28). Can we call them siren-like? The three figures in a light subdued tone of colour, are certainly wanting in contour; in the centre and right hand figures the lines of neck and shoulders are ungraceful. The other contributions by this artist are better, and to some of them we shall refer further on. Mr. Britten, in "Musie" (32), has scarcely given us the ideal sentiment suggested by his theme; the figures are wanting in grouping and composition, and the faces wear a wild expression that looks out of harmony. We hardly know how to estimate at its real worth Mr. C. E. Halle's subject "To God and My Lover's Right Arm." If it is intended to be figurative, it certainly misses the mark: we cannot call it idealised; yet there is a Titian-like richness of colour, breadth of light and shade and manipulation, that give evidence of power, irrespective of the scale attempted. It forms at least a striking subject from the Vestibule gallery: the mounted female figure is illumined and painted with effect, and distance certainly "lends enchantment" to the picture. For idealised and refined sentiment Mr. J. M. Strudwick's work always charms. His subject No. 35, from Solomon's Song, v. 2, "My beloved is gone down into his garden, to the beds of spices, to feed in the gardens and to gather lilies," is a small picture, in a low scale of colour and in a conventionalised style of drawing, that reminds us of the earlier Italian school. There is much delicacy and tenderness in the treatment. His "Isabella" is also a composition remarkable for a pre-Raphaelite mannerism and fine, almost mechanical, execution, combined with emotional tenderness in the piteous look of Isabella; the architectural detail is weak. "Night and Sleep" is the title of a large painting by Miss E. Pickering, displaying much imaginative power. The composition, drawing, and colour are skilfully managed in the trailing garments of Night and the falling blossom from Morpheus. The little panel subjects by Mr. C. Fairfax Murray (38 and 39) are rich in composition and colour; while in another branch "Ship-building" (43) is a clever study of figures and river-side, painted with much truthfulness. We note also near Lady Waterford's picture of "The Wise Woman's Briar," founded on an old superstition, rich in colour, though crude; and Mr. J. R. Weguelin's "Tired Dancer" (45), graceful in composition the flowing red tarlatan drapery of the dancer being well drawn, and with dramatic effect. But we must pass on, noticing "The Widow's Acre" (51), by Mr. G. Boughton, a vigorous mellow landscape, and Mr. R. B. Browning's "Unanswered Question" (52), an old man holding a skull deep in the thought it inspires—the last powerful and touching; a portrait by Mr. Millais (53), till we come to two remarkable life-size studies by Mr. J. M. Whistler, that will probably attract attention, if not admiration. No. 54, "Arrangement in Brown and Black—portrait of Miss Rosa Corder," is a gracefully painted portrait of a young lady in the two sombre colours, quite intelligible; but the

next, "Harmony in Yellow and Gold—portrait of Miss Conno Gilchrist," excepting the harmony produced by two shades of yellow—raw sienna is the nearest approach to the tone—can scarcely be deemed more than an unfinished picture in which the artist had only rubbed in the shades of colour for after-finish. The drawing is coarse, stiff, and formal. Very dreamy and streaky is the same painter's "Harmony in Green and Gold": the harmony is certainly there, but it is the harmony nearly every painter's work assumes that is not finished. But we believe Mr. Whistler belongs to the school of "Impressionists"; we therefore beg pardon. Mr. Lawson's picture (57), "A Silver Mist," Mr. R. Lehmann's "Convent Dole," are both clever; the latter is very feeling and rich in tone, and sustains this master's reputation as a figure-painter. Mr. A. Legros sends a large canvas, "Jacob's Dream," powerful in colour, though the recumbent position of Jacob is awkward. His "Study of Head" (64), painted on the bare canvas, is clever. Mr. Morris, A.R.A., exhibits, as usual, some pleasing subjects, one, "The Holiday," girls skipping, and "Autumn." Mr. Macbeth's "Our First Tiff" (70), a young lady and gentleman under a huge yew-tree; the latter is reading a newspaper, and does not respond to the attention of his fair partner. The subject is pleasingly painted and minutely finished. At the end of the large gallery we come to two striking pictures by Mr. G. F. Watts, R.A., both classical, and exhibiting masterly composition. "Paolo and Francesca" is stiff in the drapery, but the gray tints and the handling are forcible and suggestive. "Orpheus and Eurydice" (74) is grandly conceived; the figure of Orpheus, who is apparently represented bearing his dead wife, is finely drawn; but the undraped figure of Eurydice is painted unnaturally, and can hardly be called successful. The same artist exhibits a portrait of Mr. Gladstone. Mr. J. D. Linton's "Les Emigrés," is one of the best of his pieces, and there is some clever painting in it, stamped by much feeling and expression. His "False," and "Early Scene from Gil Blas," are highly-finished pictures, with much dramatic power. We have before alluded to the latter. We remark "Little Elaine" (71), a softly-painted, childlike face, executed with considerable feeling, by Mrs. Anderson; "A Decorative Centre-piece," by Mr. W. Crane (72), symbolic of the seasons; and some highly finished studies by Mr. James Tissot, whose "Orphans" make an attractive picture on the walls. The "Hamnock" is a pleasing study of home life, carefully and brightly painted. In the east gallery we note casually a broad bit of foliage called "Mark-Ash, New Forest," by W. Kämpel, a life-size full length sitting portrait of Thomas Chapman, Esq., F.R.S., by Mr. E. J. Gregory; "Perdita," by F. Sandy; "Weed Burners," by David Carr, treated decoratively; Mr. Mark Fisher's "Spring," (137), a cleverly handled study of blossom; "Dorothy," by Mr. G. F. Watts, R.A.; but Sir Coutts Lindsay's "Ariadne," is the lion of this gallery: it is boldly conceived and luminous—scarcely the ideal figure we have in the Homeric account certainly—but still refined in drawing and in the treatment of drapery. The blue sea makes a good background to the draped figure, and the pose, modelling, and turned head are graceful. We must not overlook a charming monochrome painting by Mr. J. D. Connor, "Staircase of Burgos Cathedral." The handsome scrolled ramps and flights of this interesting Renaissance church are drawn with exquisite care and feeling. Refined in sentiment is Mr. Stillman's "Pametta Singing" (158), while Mr. Staple's "Not at Home" is clever in drawing, light, and shade. Mr. Walter Crane's "Panels for Decoration" are bas-

reliefs conceived in a thoroughly Classical spirit, and intended to be executed in bronze. They are perhaps rather severe in outline, and the panel representing "Evening" is one of the best of the four. Mr. E. Burne Jones occupies a large space of the east gallery; one subject he has chosen is a classical fiction, the story of Pygmalion, told in four tableaux. The first, "The Amuniation," is a life-size representation conceived in too prosaic a spirit to commend itself to us. The bay-tree, the porch, and the standing figure of a woman, are mannered, and are not suggestive of much beyond. The other four subjects are skilfully drawn in low tone, and tell the myth with much feeling. Mr. Albert Moore sends a pleasing figure-subject called "Topaz" (172), in which the artist has endeavoured to give us a symbolised treatment of the gem; and it must be confessed that in the choice of the tints and the drawing he has succeeded. It represents two figures of maidens standing against a background of light, gold-figured drapery; they are clothed in graceful vestments of light green, and have necklets of pearls, and a topaz in one of them. The head of one of the figures, relieved by shadow, appears to stand out like a relieve from the draped background, and the whole conception is delicately handled and suggestive. A study of a girl's head, by Mr. G. E. Hicks (175), is clever; and Mr. A. F. Payne's "Dream Life," a girl musing over a book, with a rich, tapestried background, is admirable in execution and tone. In the vestibule we see Mr. Whistler's pieces, "Nocturne in Blue Green," and "Blue and Gold" (192, 193), in a style which has lately given rise to so much ill-merited attention and criticism in high quarters; and a few other subjects, one of the best of which is Mr. W. T. Richards' vigorous coast scene in New England (195), and some pieces by A. Hertel, Miss Stuart-Wortley, Miss Defries, R. Lehmann, J. O'Connor, Kennedy, &c. In the water-colour gallery the chief pieces are by Mr. Richard Doyle, remarkable for some broadly-sketched foliage. His "Pied Piper of Hamelin" is suggested by a passage in Robert Browning. No. 235 is another bold sketch. We also note Nos. 251, 248, 256, 267; but the water-colours certainly do not sustain the reputation of painters in that school.

NEW BUILDINGS IN THE CITY.

THERE are some signs of architectural activity in Fleet-street and Ludgate-hill, which indicate the expiration of leases and the continuance of the reconstruction of these noted thoroughfares. In many instances the premises which line this central artery to the City have long outlived their original design and purpose; shops which fifty years ago might have answered the demands of trade are now beyond alteration, and one by one we see new fronts taking the place of the old ones, extensive premises, where possible, having been built beyond the original limits of the buildings upon the areas in the rear. Every now and then a clearance of a few houses takes place and a gap is made, which is filled quickly with new houses; though, beyond the greater conveniences conferred upon the tenants themselves, we fear the admirers of the old street will have little to be thankful for on account of the change. Unfortunately, the rebuilding of our old City streets must be regarded, even from a sanitary point of view, rather as a calamity than otherwise, as it is invariably the substitution of larger and more obstructive buildings for smaller ones. In every instance a considerable reduction of light and air takes place, injuring not only those who live close and in the rear, but also those on the opposite side of the street. The process of rebuilding certainly

results in improvement in some other respects. It allows for the reconstruction of old walls and foundations dilapidated and dangerous, crumbling with rotteness or saturated with unwholesome matter, and it enables some of the provisions of modern sanitary science to be carried out in their integrity. These are unquestioned benefits. If we take, for example, the opening up of the dense mass of premises between St. Paul's and New Bridge-street in Ludgate-hill, a decided public improvement has been effected by the removal of a nest of dilapidated houses of the most rotten and unstable description. Moreover, in this instance the setting back of the line of frontage in Ludgate-hill about 15ft., and the formation of an open space, has conferred an immense boon on the occupants. It may be of interest to notice how architectural considerations have been met in these alterations. In Ludgate-square one or two warehouses have been built having some pretence to artistic effect; but the treatment of the recessed frontage towards Ludgate-hill can at present only be judged by a narrow stone facade to some premises destined for the "Capital and Counties Bank." The elevation is in a plain, panelled pilaster style, the windows being closely set and separated by pilasters which run through all the stories, with the horizontal divisions slightly broken round them between the window openings. The chief merits of the style is that it is quiet and devoid of affectation or carving, the main effect being got by the vertical - moulded lines and discontinuous horizontal members. On the cornice of the second story is an iron balcony railing, above which the upper story forms a kind of attic. We understand the architects are Messrs. Joseph and Pearson. On the other side of the opening into the square we believe similar premises are to be built, the upper stories being carried by iron staircases, one of the least satisfactory necessities of street architecture in crowded cities. In Farringdon-street, adjoining the Congregational Memorial Hall, Mr. Vickery, architect, is engaged upon a lofty block of buildings, apparently intended for offices. The front is of red brick and stone, of Italian design, though there is little to remark upon, except that stone arches and carved capitals will be rather strong in the elevation; but the scaffolding prevents at present the formation of anything like a critical opinion on the work. One of the most remarkable new buildings in Fleet-street, not far from Messrs. Collinson and Lock's pargetted front, has been erected lately from the designs of Mr. T. Knight, of Cornhill. Between the second and third stories is a long panel in red tiles, with majolica mouldings, in which the name "The Popinjay" is inscribed,—inaccurately spelt with two p's, by the way. What the connection of the name of that bird has with the present building is not very apparent, but an alto-relief in stone of the bird itself occupies a canopied niche between the first-floor windows, while from the label mouldings above them are medallions of rococo design, with heads carved in the red Mansfield lintels, and represented as being suspended from the centres. A tablet, also inscribed, is introduced between the second-floor windows. These introduced features have more the recommendation of novelty about them than anything else. At any rate, we think Mr. Knight's building would have lost little by their omission, except that the other features of the front would not have attracted the passer-by. Red brick, with Mansfield stone in the carved portions, and lintels, have been used, but the brickwork has suffered much from a white efflorescence or "salt-petring." In the treatment of the ground story we think an opportunity has been lost in not taking advantage of the open passage which occupies a portion of the frontage.

The pilasters, of red, polished granite, and the caps, are weak. Interiorly, above the shop, several large and well-lighted offices are obtained, approached by a spacious staircase, entered from the passage, and these will no doubt be readily let.

A few yards nearer the Strand a large gap till recently occupied by old houses half built of timber, has been filled by two new buildings. The largest and most important of these is intended for a new hotel. It is of red brick externally with stone introduced in the window dressings and lintels. The façade, from its present appearance, is intended to be in a sort of Renaissance, and to display a little variety in its treatment. On one side of façade is a bay window of stone with angle pillars and carved capitals, while on the other side the windows are large flat lintelled openings with pilastered jambs. A wide corridor entrance relieved by pilasters leads to the principal staircase, and forms a feature in the elevation. Messrs. Ford and Hesketh, of Aldermanbury, are the architects, and Messrs. Browne and Robinson the builders. On the east side is a smaller front, erected by Mr. Hobson, builder, in white brick and red dressings, the only feature of any remark being an arched entresol. These two buildings occupy the frontage of several old houses, and are considerably higher than the adjoining buildings. Undoubted opportunity for architectural skill is met with in Fleet-street in the management of the passages and alleys that exist on this north side, and in preserving as much as possible the associations connected with this famous thoroughfare. Between St. Dunstan's Church and Fetter-lane there are two old houses of much interest archaeologically as excellent examples of 17th century London. One is occupied as a secondhand bookshop. These houses still retain the old two-storied bay windows, with their richly-moulded and dentilled cornices, and the balconies above. The sides of the houses are still enriched by the Ionic pilasters, and, with the gabled tops and cantilevers to balcony, suggest to us a rough idea of what Fleet-street was in the earlier days of the Revival. They are thickly-coated with plaster and paint, and are chiefly of timber construction. We may express a hope that these will be tenderly dealt with when they come to be removed, as in all probability they will before long. Another block of four old houses, with even greater architectural pretensions, opposite St. Mary-le-Strand, call for equal consideration. In these the fronts are entirely of timber and plaster; the architraves and window dressings are richly moulded and carved, and exhibit the classic taste of the Stuart period. Pedestrians cannot fail to observe another improvement at the junction of Fleet-street with the Strand, namely, the removal of the hoarding opposite that portion of the new Law Courts that has recently become occupied, an additional width of pavement having been thrown into the street by this and the concurrent clearing away of the stump of the northern pier of Temple Bar. The removal of the barrier has given an opportunity for a more complete estimate to be formed of this portion of the great work of Mr. Street. The eastern tower is now revealed in its full proportions. We cannot quite agree with one of our daily contemporaries that the structure is something between a church tower and a chimney: it has far more of the fortress character of the towers of feudal France in its composition; and the least successful part of the design is the flat heavy buttressing at the sides of the eastern quadrangle archway. Shortly the block of houses between Bell-yard and Chancery-lane will have to be dealt with, and an opportunity will be offered for an architectural frontage of some importance.

Mr. F. W. Stocks has been appointed assistant surveyor of Accrington.

MR. STREET ON ART CULTURE.

SCHOOL OF ART prize distributions have lately been made the occasions of art utterances and the policy of art students, much after the fashion set by ex-Parliamentary orators. Mr. G. E. Street, R.A., has been lecturing to the art students of Sheffield as Mr. W. Morris did not long ago to a Birmingham audience of students. Mr. Street's address—to which we commend the attention of our readers—will be found fully reported in our last issue. The former gentleman, in some clever remarks, deplored the debased taste of the nation, but scarcely gave us so much as a hope of improvement; Mr. Street dealt with the same subject in a more practical manner, and while lamenting the general art apathy of the English people, does not despair of redeeming them. The remarkable conflict between artistic impulse and civilisation was explained in a far more satisfactory manner than we have been accustomed to hear, though to any intelligent mind it is simple enough. Mr. Street observes: "It is indeed a truth about which we cannot have any doubt whatever, that there is a certain kind of civilisation which whilst it raises some men, tends to debase the majority to a very low level in all matters of taste, and in all natural artistic development and expression. The reasons for this do not seem to me to be far to seek. The perfection of machinery, for instance, enables an enormous number of men to earn their living by perfectly adapting themselves to one process, to the complete exclusion from their thoughts of all others. And such a mode of work involves consequently a loss of intelligence, which is hardly compensated by the perfection to which the machine—and the man as part of the machine—succeeds in attaining." We commend this only logical way of looking at the question of what we may here call "Machinery versus Intelligent Labour" to those who are for ever wondering how it is, and deploring the fact, that the civilised modern workman cannot give us half the beauty and the interest of the workmanship of former times. But though we may lament the result, it is ridiculous for us to wish for a return to the old system, to protest against machine labour as the cause of artistic degeneracy. We might as well find fault with all our civilising agents. It is not the machine so much as the man that allows himself to become part of the machine that is at fault. As Mr. Street said, nothing that the workmen of former days did "was ever absolutely vulgar, hideous, or commonplace, or false in its mode of dealing with material, or in its suitability for its purpose." Every piece of old furniture which our cabinet-makers and connoisseurs copy and go in raptures over just now, exhibits thoughtful labour, as we have before hinted, rather than time-saving labour. The question at once suggested, is how to correct this state of things, and Mr. Street thinks justly that it is not merely the imparting to our students the mere faculty of drawing, as the power of discrimination between good and bad in art. We venture even to say that our Government schools have taught too well the mere mechanical modes of execution, and have neglected the culture of the power of discerning good from bad art, or beauty from deformity. They have done excellent service as regards the penmanship of art, but they have not so thoroughly taught the student to rely upon his own resources in the power he has or should have of perception. The mode of instruction is to give the pupil an example of flat ornament—it may be a portion of a frieze to a building he does not know, and certainly is perfectly ignorant of its purpose or position. The ornament is copied and the mere exactitude of the reproduced drawing is looked upon as the test of the capability of

the student. Prizes are bestowed for the excellence of the drawing—not upon the artistic perception of the pupil. It is this system we have always deplored as well in the Government schools of design as in the training of the young architect. It tends to the making of copyists and drawing machines, not intelligent artists. Mr. Street might have added that the mediæval workers had no schools and no drawing facilities. There is undoubtedly more to be learnt by seeing and thoughtfully examining our museum collections, than in simply copying in a vacant, mechanical and listless manner. Again, the lecturer said, whatever is to be "in frequent use and constantly before the eye, may be an artistic work and ought—if it is ornamented at all—to be ornamented well." We desire to emphasise the little word "if" because Mr. Street's meaning is not fully understood without it. The curse of modern art has been ornamentation—something added for the sake of making an object "pretty" or attractive, and to make it worth more, and it is very certain that the true artistic meaning of this word is not intelligible to the ordinary art student or decorative artist. The value of the museum and such collections as those of South Kensington was rightly insisted upon as furnishing the *motif* of the old artist in the hammered metal work and other domestic utensils of his day.

But one of the leading principles inculcated by Mr. Street was self-reliance upon the eye and hand. The study of the human figure is of course placed first. He said:—"The mere habit of drawing well and carefully from the life, or from the purest antique sculpture, gives a natural sense of the beauty of lines and curves such as cannot be obtained in any other way with equal certainty." The difference in this respect between the sculptures of the Parthenon and the later Roman work was pointed out. Mathematical accuracy and repetition were strongly repudiated, as productive of monotony, and the most certain evidence of poverty of invention and artistic feeling; and Mr. Street very plainly enunciated the proposition, and very forcibly dwelt upon it. One of the advantages he claimed for the human figure was that it led the student "insensibly to indifference for some qualities which at the present day have great and most noxious influence throughout this country." Accuracy of workmanship, and exactitude to the minutest points of line and colour, are without doubt overrated and ordinarily esteemed as one of the necessary conditions of artistic merit; but Mr. Street endeavoured to disabuse the minds of his audience of the idea. So long as exactness and repetition are aimed at, we cannot expect to see real or feeling art of any kind; the two cannot co-exist. The "variety which is absolutely incompatible with exact accuracy of execution is really the highest quality which any of man's works can have." This will appear to some the language of the enthusiast; but Mr. Street exemplifies the principle in his own works to perhaps a greater extent than many, and no one with any real art feeling can deny that it is one of the most powerful sources of beauty both in nature and art. "There is nothing," it was said, "that has done so much harm to the art of design as the too-frequent dependence on mathematical drawing instruments. If a man wants to design an ornament, he brings all his dividers and his bow pencil. He divides out his ornament with an accuracy which aggravates us, and never trusts to his hand to draw a curve whilst he can get his bow pencil to do one for him." Few, we should say, are so ignorant of Greek art as to believe the best Greek ornament was entirely an affair of the bow pencil, though the observation upon this was well-timed. The tracing and repetition of set forms was well censured as a most pernicious mode of designing ornament, and we commend

especially these remarks to the student. Mr. Street's illustration of the value of dependence on the eye and hand in the old Venetian glass and the Doulton ware was admirably to the point; he showed in this instance what may be showed in other manufactures, that the aim of the Venetian glass-maker was entirely opposed to that of the English artist, who conceives absolute uniformity necessary to good work. But our chief business here is to recall a few points in Mr. Street's address to the student's attention rather than to comment upon them. No other utterance has appeared for some time past so full from beginning to end of such valuable maxims so moderately enunciated, and so free from the extravagances of sentiment and expression to be found in the teachings of some masters.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

DISCUSSION ON ARTISANS' DWELLINGS AND THEIR IMPROVEMENT.

AGREEABLY to our promise last week (p. 443), we give below a report of the two nights' discussion at the Institute which followed the reading of Sir James Watson's paper on "Improvements and Artisans' Dwellings in Glasgow."

After the reading of the paper, the PRESIDENT said Sir James Watson had opened a critical question, that of improved dwellings for the poor. There was no need to inquire as to the necessity for such; the problem was, admitting the need, how unhealthy houses could be demolished and better ones erected, so as to be within the sum that could be paid as rent by the very poor. The pecuniary difficulty of housing this lowest class was so great that he believed even the company of which Sir Sidney Waterlow was chairman had shrunk from facing it. Various items in the outlay involved—the cost of erection, of maintenance and repairs, rates and taxes—could not be economised, but he suggested that the expenditure on land might be. It would be well if the Metropolitan Board of Works would let their vacant lands for this purpose at a low figure, or even offer it gratis to facilitate the objects of the companies who sought to provide accommodation. The great water and gas companies ought to feel also that they had a public duty to perform and should reduce their charge below the ordinary scale. He saw in the room Mr. Torrens, M.P., who had contributed a valuable article on this subject to *Macmillan's Magazine* of this month, and they would be pleased to hear from him how his Act of 1868 could be made something more than a dead letter.

Mr. W. T. McCULLAGH TORRENS, M.P., explained that the Artisans and Labourers' Dwellings Act of 1868, known by his name, was completely altered and its most useful provisions destroyed when in the House of Lords, so that the Act was in reality only a fragment of the measure he proposed and of that which the House of Commons approved. Lord Westbury and others thought they knew better than the promoters of the Bill what was wanted, and held that if the ground were only cleared of unhealthy dwellings, private enterprise would step in and do the rest. What had happened? After eleven years' trial there were acres of land in London lying as bare as churchyards, while the unhappy inmates, who once found some sort of shelter on the site, were still more closely cramped up and saw this vacant space lying idle year after year. With the noble incentive before them of what had been done in Glasgow, and the horrible condition of some parts of London, he, as a member for a metropolitan borough, would implore his hearers to urge on the Legislature the necessity, for manners and decency's sake, not to allow things to go on as at present for another session. He had brought forward a bill identical with his former one as it left the House of Commons, for the extension of his Act, which would soon expire from flux of time; but if this were not the best means of abating the nuisance, he would gladly support a better. Slums would never be eradicated from towns; they might be reformed and would relapse from time to time. The work therefore must be continuous, the powers to grapple with the evil ought to be placed in the hands of a local authority, so that

local knowledge and interest may be brought to bear upon the work of demolishing, repairing, and rebuilding. He appealed to all to bring their moral influence to bear on the Legislature in this matter. He highly congratulated Sir James Watson on what had been done in Glasgow, and wished they could follow so good an example in London.

The PRESIDENT wished to ask Mr. Torrens two questions: What were the proposed improvements in the Act of 1868, and what moral machinery would he recommend for influencing the Legislature?

Mr. TORRENS replied that the Bill of 1868 would be re-introduced as it left the House of Commons, but amendments would be made in it in committee. Its powers would be made compulsory and not permissive, and it would aim at renewing and replacing unhealthy and overcrowded dwellings by a slow and gradual process. It was a piece of cruel hypocrisy to say that the working population could go out of town. Let them go out of town? Let them go to the devil! How could the very poor be expected to come several miles to work in such weather as we have had? As to the second question, he could not venture to suggest the mode in which the members of the institute should exert their influence on Parliament: he could but point out its desirability.

Sir SIDNEY H. WATERLOW said, after an experience of 15 years in attempting to provide houses for the poor, he seemed to have come to a dead-lock. He had pointed out to the Corporation of the City of London that they had had land lying idle for 40 years because of the restrictive price they set on it, whereas if they had even given it away it would have paid on assessments more than they could possibly hope to realise in the future. The Metropolitan Board of Works, in a similar way, had land on hand because they estimated its value so highly that it could not be taken up and made to pay. Of eleven sites set apart, under the Act of 1872, for artisans' dwellings, only three had been built upon, and of these but two were as yet in occupation, and yet every facility was availed of for letting. In this the Metropolitan Board of Works were not to blame, as they were dealing with the money of ratepayers, and it was their duty to get a fair price; but the defect was that the increased value of assessments realised by early letting was an argument which had no force with the Board of Works, as it was an aggregation of vestries, and the profit would fall to an individual vestry. What the Board ought to do was to put the land up to auction, and, if the reserved price were not bid, to wait a few weeks and try again. If after three or four public offers by auction no one would offer the price asked it would be apparent that it was beyond the market value, and the Board would feel that it was doing its duty in accepting the highest offer. He believed the highest sum paid for land in Glasgow—1½d. per foot—was one at which the land could be remuneratively covered. The company of which he was the chairman had offered the Metropolitan Board of Works twice that sum for sites, but it was declared to be insufficient, although the company had found no difficulty since in purchasing land of private owners at a lower rate. His company had spent nearly half a million of money in the prosecution of its aims, and when he told them that they had never had any trouble as to lights, &c., it would be understood that some discretion had been used in planning and building. There was very much to learn from Sir James Watson's paper, and the author was much to be congratulated on the success achieved. It appeared that in that city the demolition had been very gradual, and new houses were provided faster than others were pulled down. This did not seem possible in London. The model of a Glasgow lodging-house he had only seen for the first time, but he highly commended the plan and arrangements. He concurred in what the President had said as to the duties of water companies. His company had found great difficulty in this matter, as the water companies positively refused to allow their tenants to be supplied by meter even at the highest rate. What had been done by his company was to have large tanks on the roofs of the dwellings, and allow the tenants to use from these freely. If the supply ran short the waste was traced as far as possible to the particular tenant. An alteration was about to be made in the terms of the Public Works Loan Commissioners, which would, if the Bill

were carried, seriously increase the cost of borrowing money at the outset when it was most difficult to raise funds; and he trusted this would not be made applicable to societies like that with which he was connected.

Mr. VULLIAMY explained the plans of the eleven schemes now being carried out under Mr. Cross's Artisans' Dwellings Act by the Metropolitan Board of Works. They provided for blocks of buildings of four or five stories high, with streets and spaces 30ft. wide between; the spaces at the rear were to be asphalted and could be used as playgrounds by the children. The only site entirely cleared was that portion of the Limehouse and Whitechapel scheme, to the east of the railway; but no response had yet been made to the offer. In the Bedfordbury and Old Pye-street, Westminster, schemes the arbitrator, Sir Henry Hunt, had given his final award; the other eight were in less forward stages. In reply to Mr. Charles Fowler, Mr. Vulliamy said his own opinion was that the price asked for the land was too high, but, of course, he was but the servant of the Board. In any case, the dwellings must to some extent be provided at the cost of the ratepayers.

Mr. HOLLACE JONES described the two schemes in the City. Both had been executed, but they paid the undertakers barely 4 per cent.—not a sufficient return considering the cost of removal. The price paid per foot was 6d., and he thought that too much.

It being now twenty minutes to 11 p.m., the President proposed an adjournment till the following evening.

TUESDAY.

The adjourned meeting was very thinly attended, only a dozen members, in addition to the President and Secretary, being present throughout the evening.

In reply to a series of leading questions from the President, Sir JAMES WATSON said the builders of Glasgow could not give more, upon an average, except near the centre of the city, than 30s. per square yard for land upon which to erect working-class dwellings, equal to 1½d. per foot per annum; they considered that no higher price would repay them 6½ to 7 per cent. on their outlay, the usual rate of profit in the Glasgow building trades. This was for the freehold of the sites. He could not say as to the cost of maintenance and repairs, nor the average of unoccupied dwellings, as the management of the properties did not remain in the hands of the civic authorities. Sir James explained the arrangement of the model lodgings by a wooden model on the table. It was intended for single people, and consisted of a stone walled house, divided on each floor by wooden partitions into a series of narrow compartments, so planned in pairs that a recess in one afforded a sleeping berth, while on this in the next cubicle rested a second berth reached by a flight of steps. The cubicles were 10ft. high, had cross ventilation, and were lighted above the doors; the average capacity was 960 cubic feet for the pair. In the model lodgings, while the walls were of stone, the floors and cubicle partitions were of wood; the authorities were considering the advisability of compelling these to be made fire-proof, and especially of enforcing iron partitions. He had himself been for many years a manager of a trust, to provide these lodgings, on the basis of aiming at a return of 5 per cent. on the money borrowed, and giving any surplus to a charitable institution. The trust had three blocks of lodgings, two for men and one for women, which they let at 3d. per night per cubicle, throwing Sunday in. They did not pay for some years, but the result of thirty years' trial had been that they had returned the stipulated 5 per cent. dividend, including back payments for the years of struggle, and had handed over to the Royal Infirmary donations from the surpluses amounting to £16,000.

Mr. JOHN HONEYMAN, of Glasgow, mentioned that when the scheme for artisans' dwellings was under consideration the municipal authorities engaged five of the principal architects, not in competition, but each retained by an honorarium, to give their professional opinion as to the best mode of covering the vacant ground with dwellings. He had the honour of being one of the architects so engaged, and considered the method one that might well be followed in other towns. However successful the Glasgow corporation and the trust might be, he did not consider that they had solved the real problem, how

to provide for the very poor. As far as that object was concerned, not much encouragement could be gained from the operations in Glasgow. The policy adopted there had been to disperse the working population; he thought it a mistaken one, and that it involved much hardship for the poorest class. The dispersal was enforced because of a mistaken idea of a connection between density of population and health and mortality, but under good sanitary conditions a dense population was as healthy as one more widely scattered. The great aim should be to provide cheap and comfortable dwellings for the extremely poor as near as possible to their place of work. Where the water and gas works were in the hands of a corporation that body might be fairly asked to reduce the rates. When municipal authorities offered land for these purposes it was not wise to ask too high a price, nor to burden the builder with unnecessary restrictions as to height of stories and vacant areas. Replying to a question from Mr. Wyatt, Mr. Honeyman said working-class dwellings were erected in Glasgow for about 6d. per cube foot. If in London buildings of this class could be erected after paying from £3 to £4 per square yard for the site, the builders of Glasgow had much to learn from the metropolis.

The PRESIDENT read figures furnished him by Sir Sidney Waterlow as to the cost per cube foot of the blocks of dwellings erected by his association between 1865 and 1874, from which it appeared that the cost varied from 5d. to 8½d., but that the average was 7d. During the last four years the President said he had had some experience in the erection of this class of dwelling as architect to the Victoria Artisans' Dwellings Association. He had found that if they gave the tenants some degree of comfort, and yet built as cheaply, by which he meant as substantially and plainly as possible, the association could not build under a cost of 7½d. per foot cube. The dwellings referred to at Battersea and Stroud Vale were widely different to the simple lodgings of Glasgow. They were self-contained tenements, of from one to four rooms each, with closets and water to each, but with one w.c. to about four tenements. This was found a sufficient number for tenants of the class provided for, and considerably economised space and original outlay on fittings.

Mr. SMITH remarked that he had recently visited several towns in the north of England for the purpose of seeing how the artisan classes were housed. In several he had noticed that even in classes of houses that let at from 2s. 6d. to 5s. 6d. per week, the closets of a group of from four to eight houses were arranged in a nest or clump at the rear of the premises in two streets; these closets were on the dry system, and were kept in order by the corporations. He thought the plan of arrangement might be usefully followed in London.

Mr. JENNINGS, sanitary engineer, at the request of the President, exhibited and explained the construction of several appliances which he had invented and put up for use in the Victoria dwellings at Battersea, built from the President's designs. One of these was a sink which had a long narrow slit in place of the ordinary holes, so that the water could run off more rapidly, while by the use of a slide the slit could be closed, and the sink used as a wash-tub or other water receptacle. An other was an invention to supersede the costly and easily-damaged water-waste preventer in water-closets. It acted on the principle of the school-boy's leather sucker, which, when moistened and placed on a stone, will adhere to the stone for a few seconds owing to the pressure of the air. In the case of the closet, a solid piece of leather is placed beneath the handle, and is moistened from a bottle of oil. It sticks to the lower part of the handle for five seconds, during which time about two gallons of water can escape, but if the handle should continue to be held or triggered up the leather falls, and shuts off the water. A third was a form of trapless closet.

Mr. MARK H. JUDGE said the difference between the success of artisans' dwellings schemes in London and Glasgow appeared to be due to the fact that in the latter city there was but one governing body, whereas in London there were many. The model lodgings explained by Sir James Watson seemed, like ragged schools, to be rather a disgrace to the community, and at best but a temporary expedient for sheltering a population which had no homes.

Mr. FOWLER observed that Mr. Torrens's new

scheme acted on a principle which must render it as ineffective as the old Act of 1868; Mr. Torrens again proposed to place the power in the local vestries of the metropolis, who were not fitted to discharge the duties.

The PRESIDENT, in closing the discussion, suggested that associations endeavouring to provide dwellings for the poorer classes should be granted every facility. A local authority ought to let them the land where they possessed it, at a reasonable rate, so as to allow of a return of 5 per cent. on the outlay; the mode of assessment for rates should be rendered more equitable, and water companies should be compelled by the Legislature to supply the tenants at a fair price. In return for these special advantages, Parliament might fairly restrict the dividends of these associations to 5 per cent., at which rate there would be no difficulty in obtaining the requisite capital.

Sir JAMES WATSON having replied upon the discussion, a vote of thanks was accorded to him for his paper.

THE INSTITUTE DINNER.

THE astuteness of the council of the Royal Institute of British Architects in inviting the Prince of Wales to be present at their annual dinner was exemplified on Saturday evening in the numerous and distinguished company who assembled at the Freemasons' Hall to meet His Royal Highness. The President, Mr. Charles Barry, occupied the chair; the Prince, who wore the Order of the Garter, being seated on his right. The company, which numbered about 260, included the Marquis of Hamilton, M.P., Lord Houghton, Lord de Lisle and Dudley, Sir Alexander Cockburn (Lord Chief Justice of England), Lieut.-General Sir D. Lysons, K.C.B., Sir Seymour Fitzgerald, G.C.S.I., Rear-Admiral the Hon. H. Carr Glyn, C.B., C.S.I.; Rear-Admiral Sir Beauchamp Seymour, K.C.B., Sir F. Leighton, P.R.A.; Mr. W. Spottiswoode, President of the Royal Society; Mr. Beresford Hope, M.P., Sir Coutts Lindsay, Bart., Sir R. Wallace, Bart., M.P.; Sir P. Cunliffe Owen; Sir J. Gilbert, R.A., President of the Society of Painters in Water Colours; Mr. E. A. Bond (Principal Librarian, British Museum); Sir James Watson, of Glasgow, Mr. P. H. Calderon, R.A., and W. Calder Marshall, R.A. Among the members of the profession who were present were: Professors Donaldson and Lewis, Messrs. J. Whichcord, G. E. Street, A. Waterhouse, T. H. Wyatt, E. M. Barry, J. L. Pearson, J. O. Scott, W. H. White (sec.); C. Douglas, President of the Glasgow Institute of Architects; H. L. Florence, T. Worthington and H. Summers, Presidents of the London, Manchester, and Liverpool Architectural Associations; W. Millican, President of the Leicester Architectural Society, &c.

The toast of "The Health of the Queen" was proposed by the President, and drunk with enthusiasm.

In giving the next toast, "The Health of H.R.H. the Prince of Wales, patron of the Royal Institute of British Architects, the Princess of Wales, and the other members of the Royal Family," the President said that instead of leading a life of splendid leisure as he might have done, the Prince of Wales had chosen to occupy himself heartily, and with no stint of personal labour, in all movements which had for their object the advancement of the intellectual or material prosperity of his country. At the Paris Exposition it was now a matter of pride for this country, and worthy of congratulation to His Royal Highness, that the untiring and persistent personal exertions he made not only placed England in the foremost rank as regarded art, science, and commerce, but had much to do in inciting other nations to make the efforts which were needful to insure the splendid success which was obtained. By deeds like these, by readiness to mix with and assist his future subjects in objects which were all in all to them, but which could only claim his passing but kindly attention, his Royal Highness had gained for himself not only the loyalty, but the love of Englishmen all over the world. Since 1862, when the loss of the Prince Consort was a fresh and a deep sorrow to the nation, his Royal Highness, taking the place of his illustrious father, as patron of the Institute, had manifested the greatest interest in its welfare.

THE PRINCE OF WALES, who was received with

prolonged and hearty cheering, said:—The terms in which your president has been kind enough to give my health and the way in which you have received it deserve my most sincere and my most cordial thanks. I can assure you that it is with the greatest pleasure that I am here this evening and in your midst, not only as your guest, but in the position which I have the high honour to hold as patron of the Royal Institute of British Architects. As has been observed by your president, I acceded to this post after the death of my lamented father, who had held it from the year that I was born, and who was two years after that time present at a meeting of your institute, upon which occasion the father of your president, Sir Charles Barry, was present to receive him as vice-president. Your president has made some most flattering remarks about me—far too flattering, I fear. He has alluded especially to the late Paris Exhibition. It affords me great pleasure on this occasion—perhaps the first public occasion since that Exhibition was over that I have met a large assembly of my countrymen—to have the opportunity of expressing my thanks to that very large community which assisted me in those important labours during those two years, and especially during the one that has just passed. There were as many as eight gentlemen who composed the Royal Commission, not to speak of many others, some of whom are here this evening, who took different parts in the work which we had to do. It has been admitted that the Exhibition was a success, and we owe it to those gentlemen who assisted me in those labours, and to those great commercial, agricultural, and scientific bodies who spontaneously came forward to exhibit their goods and products, and who, with hardly any exception, responded to the call that was made upon them. The work that I did upon that occasion, gentlemen, was really but slight, and it was one both of love and of peace. Those who worked with me acted always in harmony with me, and I have to thank them again for having given up so much of their valuable time to go to Paris and assist in making the Exhibition the success which you have kindly said, through the mouth of your president, that it was. I must not forget one who is sitting at this table, to whom, I think, all of us are indebted more than to any other man—our indefatigable secretary, Sir Philip Cunliffe Owen. With regard to this Institute of British Architects, I may say that it was the unanimous opinion of an international jury that our architectural exhibits were better than those, or at any rate held very high rank, among those of all other nations. I thank you for the cordial reception you have given me, and also for the way in which you have drunk the health of the Princess of Wales, and the other members of my family.

Lieut.-General Sir D. LYSONS and Rear-Admiral the Hon. H. C. GLYN responded for "the Army, Navy, and Reserve Forces," which was proposed by Mr. J. Whichcord.

Mr. G. E. STREET, R.A., proposed the toast of the "Fine Arts," coupling with it the name of Sir Frederick Leighton. He was sure that painters and sculptors would excuse him for reminding his hearers of the fact that architecture was the mother of all the arts; not only did it afford a foundation for the sister arts, but it was essentially a public art, one in the enjoyment of which every passer-by could share, and in which everyone could take an equal interest with the patron, while the brush of the painter and the chisel of the sculptor were alike employed in the adornment of our public works. In the palmy days of art, the great painters could design cathedrals, and the best sculptors were also great architects. One would like to see that state of things revived, and he was not without hope that it would again be the case. In coupling with the toast, "The Health of the President of the Royal Academy," he would recall some of the incidents of his career. When one thought of four or five-and-twenty years ago, when Leighton's first great picture appeared, one could not but remember that the instinct of the painter was followed up by the instinct of the man who was so many-sided, and that he determined that the union of all the arts should be represented, and that the painter, the architect, and the sculptor should be depicted as carrying home a great work to be placed in a public building. But, Sir Frederick Leighton did not stop there. He had carried out some very noble work in a church in the New Forest,

and also in South Kensington Museum, and now he had in contemplation, and they all looked forward in eagerness for the work which the painter intended to add in decoration of that noble dome which soared above their great City of London. He furnished indeed in himself a notable example of that high degree of excellence which could be attained by a true artist in several branches of art.

Sir F. LEIGHTON, P.R.A., who was much cheered on rising to respond to the toast, expressed earnest hope that the consciousness of the necessity of a greater solidarity and a closer union between the sister arts which is awakening amongst us might continue to spread and increase to the infinite gain and strengthening of those arts. To this end all should work. They could do art no better service, provided only their efforts in that direction were accompanied by no vain illusions. The tendency of modern times was towards the sub-division and distribution of labour. That was the natural result of the widening and deepening of the field of knowledge, so that one single study sufficed to absorb, and even to overtax, the concentrated energy of the individual student, and that tendency had necessarily, and up to a certain point justifiably, been felt in art as well as in the other spheres of human activity. The problems of architecture, for example, were more complex than they used to be; and as it was impossible any longer to find men in whom all the knowable was concentrated, so it was, he was afraid, vain to hope for the return of those halcyon days in which painters built belfries, or sculptors cathedrals, and in which people were in doubt whether a Peruzzi should be called an architect or a painter, or a Rosellino, a sculptor or an architect. Nevertheless, that almost complete divorce between the arts which we frequently saw nowadays was not needed, was not justifiable, and was a reproach to us all; for, in spirit and in its inmost roots and recesses, all art was one. It was one soul speaking to us through various tongues—the same bright gem flashing its fire through various facets. In proportion, he believed, as artists bore that vital truth in mind, would be the dignity and the lasting value of their achievements and the influence and authority of the arts themselves.

The PRESIDENT proposed the "Healths of the Visitors," coupling with it the name of the Lord Chief Justice of England. In asking their guests to show in daily life towards members of the profession that consideration due to them, he would especially ask for that consideration and respect in courts of justice, where occasionally it seemed that architects as a class were judged by the actions of those who were unworthy of the profession.

Sir ALEXANDER COCKBURN said no one was a greater admirer of art than himself, but he appreciated architectural art and science above all, because it not only ministered to the comfort and happiness of mankind, but was inseparably associated with all the great epochs of our history, and all the great events of past times. Each important building brought back to recollection some historical incident on which we dwelt with interest, satisfaction, or pride. Where could we find anything greater, or anything that more ennobled the thoughts of man, and led him to rise to Heaven than our cathedral and church architecture? In Westminster Abbey reposed the ashes of great men who had passed away, while in connection with innumerable other of our church buildings were these great associations or historical recollections to which we should cling to the last. Only that day he had passed along that new building which was to be associated with the great profession to which he had the honour to belong, and looking up at it he was struck with the marvellous beauty of the nascent edifice. It would not be finished in his time—he ventured to think Westminster-hall would last long enough to outlast him—(cries of "No, no," and cheers)—and that it might be said of him that he was the last Chief Justice of England that administered the law in that ancient spot. Of that splendid edifice which was rising now, he said to himself that it would be associated hereafter with the great reign of Queen Victoria, and with that great change in the law under which common law and equity ceased to exist as separate branches of our judicial system. But, nevertheless, Westminster Hall would still retain its own glorious, transcendent associations to all time. It had witnessed the foundation of our liberties. That edifice might

be built over, altered, or modified, but it would never be effaced from the memory of Englishmen. In that hall had taken place some of the great trials which illustrated and ennobled English history. There treason had met its doom; there the victims of would-be tyranny and would-be judicial turpitude had triumphed over their persecutors; there his great predecessors, in whose shoes he sometimes almost trembled to stand, had administered justice through past ages down to recent times. Was he not right, therefore, in saying that architecture, which had built up these glorious structures, in which we triumphed, and which formed our exultation and our pride, was a science which could not be too highly appreciated, or too much admired? This institution stood at its head, fostering and encouraging this great and noble art. It stood upon the confines of art and science, combining both. It was an institution which every man must look to with admiration and honour, and to have been honoured by its princely hospitality was a thing to be remembered for the rest of one's life.

The PRINCE OF WALES said the task had been deputed to him of proposing the last, but by no means the least toast of the evening, that of "Prosperity to the Institute, and the Health of the President," with which he would couple the name of their President, Mr. Barry. He would thank him again for having invited him to that interesting banquet, and he would express the pleasure it had given him to dine there, as Mr. Barry's year of office would soon be over. I have to give you, gentlemen, his Royal Highness continued, the toast of Prosperity to your Institute. What greater proof of prosperity could there be than that when this society was founded, 40 years ago, you were only 20 in number, and now you number upwards of 750? When we look around us to-night and see gentlemen who have come from all parts of the United Kingdom, it shows at once the interest that is taken in this annual gathering. It must be a source of pleasure to you, and to all of us, to see among us one who has been for so many years connected with this Institute as Professor Donaldson. I allude to him as a veteran architect. He has lived to an advanced age, and I am sure it is the hope of all here present that he may long continue to grace this board at these annual gatherings with his presence. It would be useless for me to dilate on the position of this society. So much has been said this evening that if I were to dwell at any length upon the matters connected with the Institute I might be accused of what is vulgarly called "talking shop." I will, therefore, ask you, and those gentlemen especially who are here to-night as visitors, to drink most cordially the toast of "Prosperity to the Institute of British Architects," coupling with it the name of your President, Mr. Barry.

Mr. BARRY, in returning thanks, said that it was a matter of pride and congratulation that the little band of twenty members in 1834 had attained to the robust strength of 750, and it was a pleasure to see that the growth was still going on. The Institute was now approaching its 50th birthday, and might be deemed, therefore, to have reached years of discretion. It might have made mistakes in its youth, but he trusted the Institute was now settling down into a useful and honourable period of middle age. Personally, he congratulated himself upon the fact that, as his father had welcomed the late Prince Consort in the name of the Institute in 1841 and 1843, it was the high privilege of the eldest son of that father to welcome that evening the Prince Consort's eldest son.

In response to loud cries for "Donaldson," the Professor rose and briefly acknowledged the compliment that had been paid him, expressing the pleasure with which he witnessed the success of the Institute. They were much indebted to those who had held the office of president from the time when he had the honour of founding the Institute to the present time. He cordially thanked them for the manner in which they had received the mention of his name.

ANNUAL REPORT OF THE INSTITUTE.

THE Council of the Institute have issued to the members a report for the official year 1878-9 which is to be read at the annual meeting to be held on Monday next. The past twelve-month is spoken of as one of progress and

prosperity; the roll of membership shows increases in each class, the present number of subscribing members being 786 as against 709 in May, 1878. Since the commencement of the present session a change has been made in the keeping of the Institute accounts, the trust moneys having been separated from the ordinary funds. The ordinary income of the Institute for the year 1878, including arrears and excluding subscriptions paid in advance, amounted to £2,201 3s. 11d.; while the expenditure, including the outstanding accounts (£352 18s. 3d.) for the year 1878, amounted to £1,837 15s. 4d. Thus the ordinary income for the year exceeded the ordinary expenditure to the amount of £363 8s. 7d., and the state of the receipts about the beginning of the official year 1878-79 encouraged the council to devote £500 to the purchase of 3 per cent. consols as an addition to the invested capital of the Institute. Of the work effected during the year the foremost place is given in the report to the modifications and improvements made in the proposed by-laws of the Metropolitan Board of Works at the suggestion of the council. A report upon other alterations considered by the council to be desirable has been forwarded to the Home Office, but at present no definite decision has been arrived at the Home Secretary, and the by-laws are not yet promulgated. In reference to the Premises Improvement Scheme it is reported that Mr. Phipps's amended plans were found too expensive, and that the council will bring forward at the annual meeting next Monday a simple plan of rearrangement of the present premises, by which they will be rendered self-contained. A broad staircase and improved means of access, increased library accommodation, greater facilities for the transaction of business and more light and ventilation in the meeting room than now exist will be obtained. The meeting room thus altered will be made available to the members throughout the year for purposes of reading and writing; its re-adaptation to the necessities of the usual evening meetings, numbering about fifteen in the course of a session, will become a mere question of removing or adding benches. An official report on injury by and protection of buildings from lightning, embodying some thirty-six communications from members, has been prepared by Mr. John Whicheard and Professor Lewis, the Institute's representatives at the proposed Conference on Lightning Rods, and has been forwarded to Mr. Symonds, F.R.S., the secretary of the Conference. It is stated that the recommendation of the Marquis de Vogüé for the Royal Gold Medal has been approved by Her Majesty the Queen, and it is expected that M. de Vogüé will visit his country in June next in order to receive the medal. The Biennial Architectural Examination will be held on Monday week, the 12th inst., when ten candidate will be examined in the proficiency class, and nine in the preliminary class. The examiners for the year are Messrs. F. C. Penrose, G. Aitchison, and T. Roger Smith. An increase is reported in the number of readers at the library between the hours of 5 and 9 p.m. The collection has been increased during the year by the bequest of about 200 volumes by the late Mr. C. C. Nelson, and the presentation of 340 volumes (exclusive of periodicals and Transactions), and also 114 sheets of drawing and photographs. In conclusion, reference is made to the approaching retirement from the office of President of Mr. Charles Barry, and to the devotion, care, and energy with which he had discharged his duties. "By the position Mr. Barry has taken and maintained the Institute has," the report states, "been enabled to acquire a recognised standing such as it never before possessed, and the council are confident that the members must deeply appreciate the important services rendered by the President to themselves and to the profession of architects during his eventful years of office."

During the restoration of Sudbourne Church, East Suffolk, a wooden box was found last week concealed beneath the flooring of the north aisle, and in it were packed some 2,600 coins, chiefly silver pennies, in excellent preservation, of the reigns of Henry II. and Henry III., some being the productions of the Ipswich and Bury St. Edmund's mints. The style of the church is Early Perpendicular, and hence it is probable that the coins were concealed at the time of the original building of the church. The work of restoration is being carried out by Mr. H. S. Smith, builder, of Ipswich; Mr. Vincent, foreman.

THE NEW CHURCH OF THE ORATORY, SOUTH KENSINGTON—
PREMISES IN COLESHILL-STREET, BIRMINGHAM.

OUR LITHOGRAPHIC ILLUSTRATIONS.

THE NEW CHURCH OF THE ORATORY.

WE have already published four designs submitted in competition for the above church, which included the design to which the second prize was awarded, and this week we are enabled to give to our readers a series of plates illustrating the selected design, "D. O. M." (to which the first prize was awarded), by Mr. Herbert A. Gribble, Baywater. It will be seen, on referring to the plan, that the one great object aimed at was simplicity of arrangement, but providing for no less than nine chapels, one altarino and baptistry, and twenty confessionals. It was the author's ambition to make the chapels as large as the site would permit, considering it indispensable to so numerous a community and congregation. The aisle chapels measure 30ft. square, and are connected together by openings sufficiently large for processional purposes. There is an ample supply of exterior doorways, and for the purpose of ingress the doors under each campanile will be used, while those at the bottom of nave are mainly intended for egress. The small door and staircase shown next the east transept are for the use of the choir, and lead to the organ chamber over Calvary Chapel, also to the cloak room, &c., in basement. And, again in the west transept provision is made for two corbetti having communications with the first and second floors of the priest's residence adjoining. The materials proposed to be used are—for the exterior, yellow brick and Portland stone dressings, and for the interior the large columns and pilasters will be in Devon red marble, with pedestals in grey ditto; the smaller columns will be executed in Genoa green, and the walls of such material as will lend itself for future decoration. The Sacristy is a very spacious apartment, measuring 53 x 30ft., well lighted by a continuous lantern carried on a groined cove supported by carya-

tides, and will be fitted up with walnut panelling and presses. A drawing of this room and other details we hope to give from time to time. The author appears to have indulged rather freely in many features peculiar to the School of Michael Angelo, Bononini, and Bernini, &c., but probably when he becomes more familiar with the Renaissance, he may give the preference to Palladio, or his faithful disciple Sir William Chambers. A coloured view of the interior is hung in the present Royal Academy Exhibition, at Burlington House.

PREMISES, COLESHILL-STREET, BIRMINGHAM.

THE above premises were designed for Messrs. Cooper and Co., to be erected on a site having a frontage to Colleshill-street and Old Cross-street. The ground-floor contains vaults, smoke-room, and the necessary offices, with kitchens, &c., in the basement. On the first-floor is a large club-room over vaults, with lift from basement, and lavatories, &c., attached; the third-floor being used for bedroom accommodation. The exterior to be executed in pressed bricks and red Mansfield stone, with terra-cotta ornamentation, moulded bricks being used for cornices, strings, &c. The internal fittings of vaults, smoke-room, &c., to be executed in American walnut. Messrs. F. and A. Wheeldon, of Birmingham and Wolverhampton, are the architects.

MAYO COLLEGE, AJMERE.

THE Mayo College at Ajmere, which is now being built, and which we illustrated on p. 198, was subscribed for some years ago by the native chiefs of Rajputana as a memorial to the late Lord Mayo, Governor-General. Several designs for the building were prepared by officers of the Public Works Department, and rejected as more or less unsuitable. Eventually the Government of India placed the design in the hands of Major Mant, R.E., now Architectural Executive Engineer and Surveyor to the Government of Bombay—an officer who is well-known in India as an architect, and as having made Indian architecture his special study. The college is intended for the education of the sons of the chiefs and nobles of Rajputana, and has already been open for some years in a building temporarily adapted for the purpose. The new building is designed in what may be termed the Hindu-Saracenic style—a fusion of the Hindu and Indian-Mahometan styles, which has already for the last two or three centuries been largely adopted by the Rajput chiefs, and even by well-to-do commoners in Rajputana and the North-West Provinces, for not only their temples and other public buildings, but for their palaces and dwellings also. The style selected harmonises, therefore, with local traditions, and is the most suitable that could be adopted, especially as it is thoroughly capable of adaptation to the exigencies of the climate and to all modern requirements. The college provides a large and handsome central lecture-hall (which will occasionally be used for durbars), library, office, and sitting-room for the principal, and class-room for fifty boys. It will be surrounded by detached boarding-houses, built at the cost of the various chiefs, each for the quota of pupils expected to be sent from his State. These boarding-houses have already been erected, and are more or less Oriental in style. The college will be built chiefly of sandstone; but marble of several colours, which is found in the vicinity, is also being freely used in its construction. The perspective we gave was drawn by Mr. Herbert Gribble from drawings sent home by Major Mant.

THE ART OF THE ITALIAN RENAISSANCE.

DR. TODHUNTER delivered the sixth of his course of lectures on this subject in the Museum Buildings, Trinity College, Dublin, on Saturday afternoon. There was a large attendance. The lecture was illustrated with a number of excellent photographs of the works of art referred to.

Dr. Todhunter said he was in that lecture to speak chiefly of Leonardo, Correggio, and Michael Angelo. So far they had watched the steady progress of Italian art from its rude beginnings in the works of Cimabue and Giotto to its technical perfection in the hands of Montegna, the Bellini, and the great Florentines. They had now to witness the last Titanic effort on the part of men of the most astounding genius

to carry the perfection further—to set a new story upon this Renaissance Tower of Babel, whose top was already in the clouds. In these three men, with the addition of Raphael and the Venetians, the spirit of the Renaissance attains its supreme expression. Leonardo, though in point of time a man of the 15th century, rather than of the 16th century, belongs to the latter by the reach of his genius and the perfection of his style. Chronologically, he is the contemporary of Sandro Botticelli and Filippino Lippi; logically, he belongs to the time of Michael Angelo and Raphael. Born in 1452, most of his work was done before the end of the 15th century, of which he saw only the first two decades, dying in 1519. The impression made by Leonardo upon his contemporaries is distinctly felt in the many anecdotes embalmed by Vasari and other writers of the day. He was for the Florentines and Milanese much what Dean Swift is for us in Dublin, a legendary personage around whose imposing personality quite a cycle of such anecdotes gathers. In personal appearance, as in genius, he was a king among princes—moving among men like a demi-god of physical grace and intellectual brightness. Great as was the versatility of many of the men of the Renaissance, Leonardo's was remarkable even compared with that of his most versatile contemporaries—the remarkable thing being the fact that if he was a jack-of-all-trades, he possessed the rare distinction of being master of all. Michael Angelo was great as an architect and sculptor, and a painter, and was no contemptible poet. Leonardo was besides a skilled musician, who sang his impromptu compositions to a silver lute of his own designing, formed like a horse's head, and tuned according to acoustic laws discovered by himself. He was an engineer of most original genius, the best anatomist of his day, a great arithmetician and geometer. There were few regions of human activity in which he was not more or less at home. But, probably few men of great genius so favoured by circumstances as Leonardo have left so little of supreme accomplishment as measured by the amount of actual power possessed. His very versatility, joined with an extreme fastidiousness as to his workmanship resulting from the high ideal he always set before him, prevented his perpetual activity from achieving the marvellous results which his marvellous genius served to warrant his admirers in expecting. He has also been unfortunate as regards the preservation of his greatest works. Nevertheless, enough of his work remains to confirm his title to a place among the greatest. Dr. Todhunter criticised in detail several of Leonardo's works, and then referred to Correggio. To turn from Leonardo to Correggio (he said) is almost like turning from Goethe to the most sensuous parts of Spenser; but Spenser is much too serious and thoughtful to be fitly compared with Correggio. The purposeless lusciousness of some of Schubert's beautiful and interminable compositions may, perhaps, serve as a tolerable parallel; but no one in any art was ever so innocently wanton, so divinely idiotic as Correggio. Correggio's drawings, which are usually sketches in red chalk, are often very beautiful, though the beauty is rather sensuous than spiritual, his type of female faces, with their narrow chins and heavy lidded eyes, verging upon the hysterical. Between Correggio and Michael Angelo there is a gulf as wide and deep as the Atlantic. They are inhabitants of different spiritual continents, or rather of different epochs of development. Correggio is like the sylph or sylvan spirit of the later mythologies. Michael Angelo is a Titan born of the primeval imagination of the world—an insurgent spirit, whose feet base themselves on the roots of the mountains, and whose brow o'ertops the clouds. The great work of Michael Angelo's youth is the "Pieta" of St. Peter's, finished when he was but four-and-twenty. It is indeed one of the great works of his life—full of the tenderest feeling. The Virgin Mother supports her dead son on her lap, across which he lies, with his nail-pierced hands and feet and thorn-crowned head hanging languidly in the utter rest of death. The mother gazes into his worn but peaceful face which seems to have fallen asleep with the words "It is finished" on his lips, as if she were pondering in her breast all that love brings to her remembrance. Her face is full of no vulgar anguish. A solemn awe seems to hold her in a trance, in which things deeper than life or death are revealed to her.

HISTORY AND ÆSTHETICS OF ARCHITECTURE.

At the Royal Institution, on Saturday afternoon, Mr. H. H. Statham delivered the first of a series of four lectures on "The Leading Styles of Architecture Historically and Æsthetically Considered." The lecture was of an elementary and non-professional character, and was illustrated by large diagrams and black board drawings, and by a series of small photolithographs, handed to each person on entering the lecture theatre, of similar character to those shown at a previous lecture in the same building, and which were reproduced in the *BUILDING NEWS* of Feb. 14th last (vide p. 170 ante). The relation to Nature of architecture as an art was pointed out, Mr. Statham insisting on the point that there should be no direct copy of natural objects either in design or decoration—all must be conventionalised. Many persons could more or less definitely pronounce on the style in which a building was erected, assigning a church to Gothic, a bank to Classic, or a club-house to Italian, while they had not considered the reasons for the selection of this dress nor how it was originated, and his aim was to show that all the "styles" employed in architecture were connected by a very long chain the one with the other, and that they grew out of varied requirements of climate, material, and habits of thought. If one opened any German work on architecture a large space would be found taken up with a learned disquisition on the origin of architecture, the inevitable conclusion arrived at by the author being that we know nothing about it. Inquirers come upon the earliest remains of the art in Egypt at a period when it was far advanced, and when the country was covered with immense temples, palaces, and other buildings, the records of a high state of civilisation. The typical Egyptian temple was described, the massive walls, the double ranges of internal columns, surrounding a series of courts, and the entrance between heavy pylons being adverted to. Lighting was effected by having an internal range of columns of greater height supporting the centre portion of the flat roof, an indirect light passing diagonally between the raised and lower portions of the roof into the temple. At Beni Hassan, at a temple erected presumably about 1800 B.C., the process by which the square posts supporting the roofs were rounded off into columns might be followed: here some of the posts had their angles canted off, while in others subsequently added to the temple a second paring of the unnecessary corners made the pillars sixteen-sided. In order that the angles might be seen in a side light, the surfaces between were slightly hollowed, and hence the origin of the fluted column. From Egyptian architecture the lecturer proceeded to that of Asia Minor, and showed illustrations of Lycian rock-cut tombs, in which the ornamentation was an evident reminiscence of timber construction. The directly wooden origin of the Doric style was discussed, the lecturer expressing the opinion that a case had not been made out by its supporters, one of many arguments against the theory being that the columns in the earliest temples of this order were the thickest, whereas if of wood a much more slender shaft would be sufficient to sustain the trabeate construction, and thus it was reasonable to infer that the columns would, as the art developed, have been gradually increased in bulk if the change from wood to stone were comparatively recent. On comparing a Greek Doric temple with an Egyptian one, a general resemblance could be detected; the grouping and the approaches were much the same, but the columns were now arranged outside the cella instead of within. A cushion or celtium was now placed below the abacus and between the column and the beam it carried, and to this a wooden origin might well be accorded. The progress of Greek architecture was rapidly sketched to the period of the building of the Parthenon, in which the highest refinement and grace met, and on which more intellectual force had been brought to bear than on any other building. The mode of lighting the interior of a Doric temple was not certainly known, the hypothetical theory propounded by Mr. Fergusson being the most generally adopted. It had been suggested to the lecturer that light was admitted through the thin slabs of marble alternating with the triglyphs above the architrave and known as metopes; these were about $\frac{3}{4}$ in. thick, and transmitted a certain amount of light. These

metopes illustrated an important law in architectural design that ornament should be applied only to features of no constructional importance; thus, these tiles having no weight to bear were decorated with sculpture. Amongst the errors made in the Parthenon was a range of bas reliefs running along the wall of the cella behind the architraves and in such a position that it could rarely be seen, and then only at a very sharp angle. The most interesting feature of Greek architecture was the elaborate system of optical refinements which were rediscovered by an English architect, Mr. F. C. Penrose, when measuring and drawing the Parthenon ruins. The Greek architects noticed that a straight line of any length would appear distorted to the observer especially if another of a different angle were placed in juxtaposition. In order to obviate the unsightliness that would thereby be occasioned, a minute and carefully calculated curve, based on the conic section, was given to every line throughout the Parthenon. The columns were not straight, but were convex and slightly diminished at the top; the lower member of the pediment, with its cornice, entablature, and architrave, was curved upwards, and the raking sides curved in a similar mode outwards, while even the pavement and steps followed the same curvature, which was continued upon all four sides, some extremely nice calculations being made as to the angles. The pilasters were diminished and inclined outwards, and to the echinus of the capitals of the columns the subtle hyperbolic form was given. This extreme refinement was only seen in the larger temples of the Periclean age, no such delicacy being observed in smaller buildings. To the absence of these optical adjustments was to be attributed the heavy and unsatisfactory character of modern buildings in Greek styles. The popular notion that Greek buildings were formally arranged in set lines was shown to be mistaken, the ground plan of the Acropolis with the various temples set at different angles being exhibited in disproof. In his next lecture Mr. Statham will deal with Roman architecture, including the Corinthian order, which he regards as essentially a Roman development.

CREOSOTING TIMBER.

WE have allowed Messrs. Armstrong, Addison, and Co., of Sunderland, to speak elsewhere for themselves as to the value of creosoting timber, as we did last week two other correspondents. For ourselves, we admit there has been creosoting and creosoting, but that when the process is performed properly upon seasoned wood, or after the withdrawal of the sap and moisture, and the oil is thoroughly injected into the pores, timber so prepared is practically imperishable, the experience of every practical engineer or architect proves. There is much in the manner of subjecting the wood; the moisture should first be thoroughly vapourised by heat, and the timber exposed to a steam pressure. The effect of creosote properly applied coagulates the albumen of the wood, and gives a waterproof coating to the fibre at the same time, thus arresting the absorption of moisture, for creosote oil is quite insoluble in water. Yellow pine should be made to absorb from 10 to 11lb. to the cubic foot, and from 8 to 10lb. is generally recommended for sleepers and ordinary purposes. Mr. Robert Walker, in the case reported which has given rise to this controversy, held that the process of creosoting by hermetically sealing the pores of the timber prevented the vaporisation of the sap; but it will be seen that the process of creosoting, if performed as we have indicated, practically insures the withdrawal of all sap. But timber is sometimes hollow or decayed at the core, and no process could be expected to impart strength to a pillar which, as Mr. Bridgeman, the coroner's surveyor, said, was hollow and reduced in substance, and which apparently yielded under an excessive load. The specimen of a creosoted Scotch fir sleeper referred to by Messrs. Armstrong, Addison and Co., is upon our table. It is thoroughly sound and hard to the impression of the finger nail, even at the heart, and still retains the strong smell of the creosote after a period of 27 years' service in a most trying position, while unpreserved sleepers of Scotch fir used in the Highland railways have had frequently to be renewed in periods varying from three to six years.

MESSRS. AUDSLEY'S "DICTIONARY OF ARCHITECTURE."

PARTS 5 and 6 of this Dictionary are upon our table, and we turn over the pages with fresh interest. The work has been brought down to the word "aqueduct," which completes the first volume. It is unnecessary to say more than we have already done in commendation of this Dictionary, except that it is far superior to any subsequent attempt in the same direction we have met with. Some interesting observations are made under the article "Apostles," to which we may refer at some length. It is remarked that in the earliest works of Christian art the apostles were invariably represented by certain simple emblems, the most common of which were twelve sheep, probably suggested by Our Lord's words, "I send you forth as sheep in the midst of wolves." The sheep are usually placed in groups of six on each side of a central figure of Christ represented as the Good Shepherd, or on each side of His early symbol, the lamb. In the more numerous instances the twelve sheep are arranged in two rows of six each placed on either side of and looking towards the Holy Lamb, represented standing on a small mount, from which four streams are flowing, and invested with the irradiated or inscribed nimbus. The twelve sheep are never invested with nimbi. At the extremities towers and gates are represented from which the sheep are supposed to have issued in procession towards the lamb. Examples of these compositions are to be found in the sculptures of sarcophagi, and in the decorations of the old churches of Rome, as in St. Clemente, St. Cecilia, St. Prassede, &c. The Apostles have also been figured, though more rarely, under the form of twelve doves; but as the authors remark, unless twelve doves are represented, it will be unwise to accept them as the emblems of the Apostles. In the primitive mode of representing them in human form they appear as twelve men accompanied by the emblematic sheep, but presenting no distinctive characters. In later works they are shown as aged men standing in a line or seated on thrones on either side of a figure of Christ, and each carrying in his hand a volume or scroll. Sometimes they are individualised by having their name inscribed near them. Messrs. Audsley refer to a "Guide to Painting," written by a Greek monk, of Mount Athos, named Pensilinos, as a work of some importance bearing upon this subject. See M. Didron's "Manual of Christian Iconography." Speaking of the order in which the Apostles should be represented, the authors say the Early or Mediæval artists did not settle any. Different arrangements have been adopted, but the Greek list given in the "Guide to Painting" is as follows:—St. Peter, St. Paul, St. John, St. Matthew, St. Luke, St. Mark, St. Andrew, St. Simon, St. James Major, St. Bartholomew, St. Thomas, and St. Philip. In Western arrangements the Apostles St. James Minor, St. Jude, and St. Matthias appear instead of St. Paul, St. Luke, and St. Mark. In Western Mediæval works which display Byzantine influence, as in the pulpit in the Cathedral of Troyes, the Greek order is met with. The Canon of the Mass is supposed to be the highest authority on the arrangement and order of the twelve apostles, according to the Latin Church. It is observed, "Except where their names are inscribed, it is a matter of difficulty to individualise the apostles in works of art executed prior to the beginning of the fourteenth century, but in the sculpture, glass and painting of the 14th and 15th centuries there is seldom any ambiguity." Long prior to the fourteenth century, emblems were given to SS. Peter and Paul. We may here give the emblems or attributes usually assigned to the Apostles in Mediæval art. St. Peter usually carries a pair of keys, the keys of heaven and hell, and a book, and sometimes a cross inverted. His lesser attributes are a church and a fish. St. Paul is generally represented bearing a sword and book. St. Andrew, the emblem of his martyrdom, a cross in the form of an X, more rarely a Latin cross, or one Y-shaped. St. James Major generally carries a pilgrim's staff and scrip or wallet, and with a scallop-shell attached to some portion of his garments; St. John (as an apostle) usually carries a cup in his hand, with a small serpent issuing from it; St. Thomas carries a builder's square, and sometimes a spear and dart, in allusion to his martyrdom; St. James Minor, a club or fuller's bat, also the instrument of his martyrdom; St.

Philip usually carries a cross, either of the Latin or Tau form, commonly placed on the top of a long staff. On several English rood-screens he is shown carrying a basket of bread, or with leaves in his hand. St. Bartholomew is depicted with the instrument of his painful death, a large knife; St. Matthew (as an apostle) has several emblems: the most common is a money-bag or box; sometimes he bears a poleaxe. St. Jude is depicted with a club, a halberd, a carpenter's square, a boat, an inverted cross, bread, and fishes. St. Simon has sometimes a fish or oar, or a saw, the instrument of his martyrdom; and St. Mathias has a halberd or axe, but occasionally a sword. The precious stones also mentioned in the Apocalypse were invested with symbolic meanings, and early applied to the Apostles. We may add that the article refers to the paintings on rood-screens where representations of the Apostles occur, the churches cited being those of Belagh, Irstead, Ringland, North Walsham, and Westwick, Norfolk; Carlisle Cathedral; Southwold Church, Suffolk; and East Wellow Church, Hampshire. The article on "Apse" is very comprehensive, and several illustrations are given, the works of Viollet-le-Duc, Rev. E. C. M. Walcott, Fergusson Texier, and Pullan being quoted.

STREET PAVEMENTS.

At the meeting of the Institution of Civil Engineers, on the 29th April, the first paper read was on "Street Carriageway Pavements," by Mr. George F. Deacon, M. Inst. C.E.

With respect to the figure of stone sets, the author explained that in order to secure stability their depth should be greater than any other dimension: but that the length should be greater than the width in order to facilitate breaking joint. His conclusions might be thus summarised:—Hard stone, in which joints were unnecessary for foothold.

	Depth.	Width.	Length.
	In. In.	Sets In. In.	Sets In. In.
Sets for moderate traffic	6 to 6½	4 to 14	5 to 7
Sets for heaviest traffic	7, 7½	4, 14	5, 7

Softer stones, in which joints were unnecessary for foothold.

	Depth.	Width.	Length.
	In. In.	Sets In. In.	Sets In. In.
Sets for light traffic or in lines	6 to 6½	3 to 14	5 to 7

A crucial examination of many classes of pavements had satisfied the author, in 1871, that those jointed with asphalt retained their figures better, and wore out less rapidly, than any others. This method of jointing, however, was often very indifferently performed. Since that date all the Liverpool pavements had been jointed in this manner with great advantage; and all those subject to heavy traffic had been constructed with Portland cement or bituminous concrete foundations. The mode of constructing the foundations and pavements differed in some important respects from that generally adopted, and was fully explained. The Portland cement concrete was mostly prepared in a yard, and not in the street where the work was going on; and the author had proved, by a large number of conclusive experiments, that no loss of strength, but probably a slight gain, arose from allowing such time as was occupied in cartage to elapse between mixing and placing *in situ*. Carriage-ways of bituminous concrete, or asphalt macadam, were next described. The smaller stones used for the upper layer of such pavements should not be much harder than the asphalt itself. A large area of this pavement had been constructed in Liverpool, and on sanitary grounds the system would probably be extended over many back streets.

After describing his experience of wood pavements in Liverpool, the author drew the conclusions that like stone pavements, they should be provided with concrete foundations, the joints should be very close, and the blocks should be creosoted.

Much difference of opinion existed as to the best mode of finishing or blinding the surface of macadamised pavements. Under a 15-ton steam roller, preceded by a watering-cart, 1,200 yards of trap-rock macadam, without blinding, could only be moderately consolidated by twenty-seven hours' continuous rolling. If blinded with trap-rock chippings from a stone breaker, the same area might be moderately consolidated by the same roller in eighteen hours. If

blinded with silicious gravel from ¾ inch to the size of a pin's head, mixed with about one-fourth part of macadam sweepings obtained in wet weather, the area might be thoroughly consolidated in nine hours. Macadam laid according to the last method wore better than that laid by the second, and that laid by the second much better than that laid by the first.

In order to compare the wear of different classes of pavements, the author had reduced the traffic to tons per annum per yard width of the carriageway, and in the following tables he compared the total annual cost of various pavements when subjected to a standard traffic.

Description of Pavement.	Original Cost per Square Yard at Present Prices.	Interest on Original Cost at 4½ per cent.	Sinking Fund Invested at 3 per cent. Compound Interest.	Maintenance per Square Yard per Annum.	Scavenging per Square Yard per Annum.	Gravelling per Square Yard per annum.	Total Annual Cost per Square Yard.	Remarks.
No. 1. Hard stone. Gravel joints. Hand-pitched foundation	s. d. 12 1	d. 6-5	d. 1-8	s. d. 0 1-0	d. 4-2	d. ..	s. d. 1 1-5	Old Liverpool pavements.
No. 2. Hard stone. Asphalt joints. Portland cement concrete foundation	15 1	8-2	0-6	0 0-25	2-4	..	0 11-45	Now constructed in Liverpool for heavy traffic.
No. 3. Hard stone. Asphalt joints. Bituminous concrete foundation	14 10	8-0	0-6	0 0-25	2-4	..	0 11-25	Ditto ditto.
No. 4. Medium stone. Asphalt joints. Portland cement concrete foundation	15 1	8-2	3-7	0 0-5	2-4	..	1 2-8	Ditto for light traffic, or steep gradients, and junctions of streets.
No. 5. Medium stone. Asphalt joints. Bituminous concrete foundation	14 10	8-0	3-7	0 0-5	2-4	..	1 2-6	Ditto ditto.
No. 6. Bituminous concrete	3 9	2-0	..	1 6-0	2-4	..	1 10-4	Ditto for back streets, and for street carriage-ways of very light traffic.
No. 7. Wood, creosoted. Bituminous concrete foundation	15 1-5	7-5	10-1	0 1-0	2-7	5-0	2 2-3	Prices if constructed by Corporation
No. 8. Macadam hand-pitched foundation ..	6 9	3-4	..	2 0-0	8-0	..	2 11-4	In Liverpool for suburban roads.

With a traffic of 40,000 tons per annum for every yard in width of carriageway, the figures for the last three pavements were as follow:—

Description of Pavement.	Original cost per Square Yard at present Prices.	Interest on original Cost at 4½ per cent.	Sinking Fund invested at 3 per cent. Compound Interest.	Maintenance per Square Yard per Annum.	Scavenging per Square Yard per Annum.	Gravelling per Square Yard per Annum.	Total Annual Cost per Square Yard.
No. 6. Bituminous concrete	s. d. 3 9	d. 2-0	d. ..	s. d. 0 9	d. 2-4	d. ..	s. d. 1 1-4
No. 7. Wood	15 1-5	7-5	4-3	0 10	2-7	5-0	1 8-5
No. 8. Macadam	6 9	3-4	..	1 0	8-0	..	1 11-4

From inquiries made with reference to the loads drawn by horses since the new Liverpool pavements were constructed, as compared with the loads drawn on the old pavements, and without giving credit for the great reduction of wear and tear of horses and vehicles, the author estimated that there was a saving in the cost of cartage alone exceeding £10,000 a year for every mile of such pavement as now laid in the Dock line of streets in Liverpool.

Of all pavements for street carriage-ways macadam appeared to the author to be the least satisfactory. It was the most costly, the dirtiest, and, on the average of all kinds of weather and all conditions of repair, probably involved a greater traction for a given load than any of the other systems when thoroughly well laid. Its dirtiness consisted not only in the excessive mud of wet weather, and the excessive and impure dust of dry weather, but also in the facility with which organic impurities were absorbed by it, decomposed within it, and exhaled to the atmosphere. In country roads this objection was insignificant, and no other pavement was better than well maintained macadam; but in some of the carriage-ways of the west end of London one would regard it as intolerable, had it not been tolerated so long. To the unsophisticated provincial the manner in which, on a hot July day, fashionable London rolled over her tainted macadam pavements, apparently without even

smelling them, was a mystery almost as great as surrounded the fact that the metropolis, alone among the great centres of civilisation in this country and in the world, still submitted with apparent satisfaction to an intermittent water supply, impure at times in almost every household, however pure the source of that supply might be, when with absolute pecuniary benefit a constant supply might be obtained.

The second paper was on "Wood as a Paving Material under Heavy Traffic," by Mr. O. H. Howarth, Assoc. Inst. C.E.

The primary point into which the conflicting

details of the street pavement problem could usually be resolved was simply this: That the conditions of road surface demanded by the two

main elements of street traffic, viz., the power and the load, were almost essentially opposed. That was, the surface most favourable to the intermittent tractive action of horses was not the one best adapted for the transmission of rolling load. To reconcile these conditions, so as to render them the least obstructive to each other, was the practical aim of road paving.

A series of observations, collected during the past three years, tended to show that against all the discrepancies which rendered comparisons of street traffic doubtful, opposite conditions had been found to arise by which they were compensated in the long run; and that, on the whole, the effect of such minor irregularities was largely controlled by the element of weight. Upon this consideration it became evident, that the formula of direct weight per unit of roadway width was that which must afford the least erroneous datum for reducing large series of traffic observations, taken under fixed rules respecting the conditions to be noted. The system adopted by the author aimed at obtaining reliable averages, by short and definite observations properly distributed, rather than from continuous counts over an isolated series of hours. The observations were collected by half-hours only, at fixed periods throughout the day of sixteen hours, from 7 A.M. to 11 P.M. in every case; such half-hours being respectively observed again on other days at the same points and in different con-

ditions of weather. The remaining night hours affording a traffic small in proportion, and at the same time subject to great irregularity with variable circumstances, were excluded, as vitiating the averages required. The system of short observations, while undoubtedly leading to a highly corrected comparative figure, was also found to facilitate the notes respecting weight, which were of necessity collected simultaneously with them. The traffic was divided under seven heads; for the most numerous and important of which the empty weights could be ascertained with precision, and the ordinary description of load estimated without any serious or cumulative error. These averages sufficed to show how widely the actual wear and tear upon any given roadway might be misconceived, in the light of a merely general or numerical estimate.

Experience afforded by recent trials pointed to the conclusion that the true theoretical condition under which wood should be used was that of a continuous and uninterrupted surface. If a whole street could be conceived to be paved with a single slab or section of fir timber, the surface well inlaid with clean grit or large sand, such road would (apart from expansive action) present, without comparison, the fairest test of the durable qualities of this material.

Upon the basis of these principles the system of paving with wood, known as Henson's, was introduced in 1875, having for its object the testing of the previous theory, that artificial structural foothold was indispensable to afford a fulcrum for tractive power, as well as to show the value of real continuity of surface, by providing the nearest possible approach to an uninterrupted area of wood only. The aim of the experiment was primarily to lay the blocks "heart to heart," upon a sound weight-bearing foundation, so as to present a continuous and uniform surface of wood on end. To such a construction the only foreseen obstacle was the variable expansion and contraction inseparable from that material under varying atmospheric conditions; and this, when accumulated over a large area, would doubtless have been of sufficient extent to become detrimental to the efficiency of a road pavement. With a view to meet this, it was borne in mind that the action of capillary expansion in wood was one which must be regarded as exercised slowly, through the minutest distances; but accumulated in proportion to the area of material subject to it. The compensation for such an expansion could therefore only be uniformly effected over a large area, by providing for the absorption of minute portions of it at the smallest possible intervals, establishing a series of minute compensations throughout the entire structure. The substance which was found in practice to be most available for this purpose was ordinary roofing-felt, from 1-16th to 1-8th inch thick, a strip of which, cut to the same width as the depth of the blocks, was interposed between each course, and thus formed a close and yet slightly elastic joint. In laying this pavement the system was adopted of driving up the blocks, as every eight or ten courses were laid, by heavy mallets and a plank laid along the face of the work, attention being given to the even range of the courses as this proceeded. The joint was thus closed as completely as possible, leaving only the actual fabric of the felt to take up the expansion, and by the mutual support of the blocks saving them from the rapidly destructive action of spreading at the edges. The protection of the wood was further enhanced by a layer of similar felt over the whole surface of the concrete foundation upon which the superstructure of wood was cushioned. Results tended to show that the several functions of this simple construction were correctly anticipated. The endurance of the wood, consequent upon its relief from vertical jarring and the mutual support of the edges of the blocks, was increased by probably not less than one-half or two-thirds. An even-grained well-grown deal, of medium weight and hardness, offered the best conditions, as far as experience went.

As regarded built roads, much was generally said upon the question of elasticity above alluded to; and it was one very commonly misapprehended. Distinction was not made between two widely different theories—viz.:—Was road-elasticity requisite as it affected the traffic, or was it desirable as concerned the road itself? Within limits, it was as advantageous to one as it was detrimental to the other. Elasticity of road was for the benefit of the traffic exclusively,

and not for that of the road; and the inference was that, if anywhere, it should be immediately at the surface, and there only. A totally inelastic road, whether absolutely smooth or designedly uneven, was open to objections, practically, on other grounds; and herein lay the chief characteristic which had brought wood into favour. Concurrently with a reasonable degree of durability, which admitted of being used to the utmost advantage, it presented always, and uniformly, a slight degree of surface elasticity, to the immeasurable saving of vehicles passing over it.

The standard of comparison, therefore, to which street pavements should be referred, must embody the two elements deducible from the preceding remarks—viz., the work performed (as represented by some systematic scale as suggested), and the sum total of direct expenditure upon it during a recognised unit of time. Of three materials—macadam, granite or porphyry sets, and asphalt—the first was beside the question, if only on the ground of its representing, under similar circumstances, a fixed charge of from 3s. to 6s. per superficial yard per annum. Granite was at the present time more nearly balanced with wood—excelling it somewhat in the matter of cheapness, but outweighed by it on the score of noise and injury to vehicles owing to its rigidity—the latter two defects insuperable, excepting at a cost which was but rarely bestowed upon it. Asphalt, labouring under an occasional deficiency insuperable at any cost—viz., absence of foothold—was nevertheless to be regarded favourably in point of cost, and would rank high so long as the definite solution of the problem of durability stood in abeyance. Meanwhile the above notable failing, together with the difficulty attending partial repairs, must detract from the value of the money-figure to be assigned to it.

In view, therefore, of the few materials at command, and of their several qualities and defects, the following questions comprise the chief issues to be decided:—

First.—Was the policy of paving for heavy traffic to aim at reduction of first cost and the retaining of certain alleged advantages attached to systems of continuous maintenance? or at the extinction of maintenance, and the acquisition of durability, combined with certain alleged disadvantages accompanying great resistance to wear?

Secondly.—Could a paved surface be made to fulfil the needs of tractive power by the intrinsic nature of any material, independently of designed mechanical form tending to obstruct free draught of load?

And lastly.—Could the durability of any description of wood, compatible with reasonable cost, be enhanced either in construction or in maintenance, so as to place it on a commercial rank with substances of greater resistance, but of less advantage in other respects?

PRINTING OR TRANSFERRING DESIGNS SUITABLE FOR WALL DECORATION.

A PROCESS for printing or transferring designs or representations upon woods, paper, and other surfaces has been recently patented in this country on behalf of L. Zweig and A. T. Tischler, of Vienna, and as it may possibly have some utility in the arts, we give a brief description:—In order to produce matrices or engravings for prints in an economical manner, it is proposed to employ peculiar metal positive prints of the designs to be copied, which are to be obtained by producing at first in low relief work the design to be copied on a zinc plate by etching the latter by galvanic action. For this purpose the zinc plate to be etched is covered with a body colour or coating in which the design to be transferred is traced by means of a tracer or graver, and the plate thus prepared is then used as a positive electrode in a galvanic decomposing cell. A second zinc plate, of the same size as the plate to be etched, and serving as the negative electrode, will be placed together with the positive plate, but at a proper distance from it in the decomposing cell. After the galvanic current has sufficiently operated upon the zinc plate which is placed in a solution of sulphate of zinc mixed with sulphuric acid, the etched plate is to be taken out of the decomposing cell, and washed in a bath of potash or soda lye, in order to remove the remainder of the body

colour. But the fact that all the engravings appear to be of the same depth is prejudicial to the clearness and sharpness of the transfer of the designs from a flexible printing plate or surface, produced by the aid of the etched plate, since besides the line raised parts, some parts also of the ground which are not intended for printing may be transferred or reproduced. To obviate this objection it is necessary to clean the zinc plate with a rag, to dry it off, and then to cover entirely all the low etched places with a mass or composition such as is used for printing-rollers, and composed chiefly of glue, glycerine, and syrup, by which operation the plate becomes perfectly even and plain. This is done for the purpose of preventing the tin from entering into the low etched places during the process of soldering. After this the widely veined parts must be more or less heightened with tin to the effect that they may appear deepened or recessed in the matrix, and that the blank or unveined places cannot be printed at once when the designs are transferred upon wood. The composition is then removed by putting the plate in warm water and the parts thereby dissolved are made even with a scraper. From the metal plate thus prepared, the printing matrices are obtained in the following manner:—The zinc plate is placed on the hollow bottom plate of a powerful press, which plate can be heated by steam and cooled by cold water. The composition to which the required softness is imparted by adding some solution of hygroscopic salt, such as chloride of calcium, chloride of zinc, or chloride of aluminium, is poured upon the oiled zinc plate, and the upper pressing plate, covered with a piece of linen of the same size as the zinc plate, is pressed down. The lower pressing plate, which must be perfectly plain and even, in order to enable the zinc plate to bed evenly and equally in all parts, is provided on its four sides with raised borders of the height of between 1-16th to 1-8th of an inch, by which the thickness of composition to be pressed upon the linen fabric will be regulated, the pressure of the upper pressing plate causing any surplus quantity to be squeezed out. During the time the upper pressing plate is being pressed down cold water is caused to flow through the bottom plate, whereby the setting or solidifying of the composition adhering to the linen fabric is much expedited. The linen, together with the composition firmly adhering thereto, and representing in relief the sunk parts in the zinc plate, discharges itself from the composition, and a matrix is thus obtained which is to be coated with a caoutchouc varnish, in order to render the matrix more resistible. The matrix is now ready for producing prints. The prints of relief designs will be made in the following way:—The matrix is passed over by inking-rollers coated with any desired colour, and is then gently pressed against the surface to be decorated, whether of wood, paper, or plastered wall surfaces, by means of a brush, and finally carefully removed from the surface. The designs now appear to be transferred on to the grounded or prepared surface; and for the purpose of fixing them nothing further is required than to varnish them as is done in hand-work.

THE "POOL OF BETHESDA," BY MR. EDWIN LONG, A.R.A.

A VERY impressive picture painted by Mr. Edwin Long, A.R.A., is now on view at the gallery of Mr. Arthur Lucas, 37, Duke-Street, Piccadilly. The subject chosen by Mr. Long, is the "Pool of Bethesda." It may be necessary to say that the picture is not a new one, that it was exhibited in the Royal Academy in 1876, but owing to the unfortunate position given to it on the walls seems to have been overlooked by the critics. No one who now sees it in the darkened room prepared for its reception at Mr. Lucas's gallery, under a light of discriminative value, can fail to remark that it possesses qualities which entitle it to rank with some of the foremost pictures of its class. In painting it, Mr. Long brought to his task a by no means common conception or mere literal rendering. He has spared no labour and study in making himself master of the surroundings and details of Eastern life in the time of our Saviour, and for this purpose visited the Holy Land in 1874-75 to examine the site of the ruins of Bethesda. The conception embodied in the picture is that particular season recorded in St. John v. when the angel descended to trouble the waters of the pool and to confer healing

power on it, the text taken being the second verse, "Now there is at Jerusalem by the sheep market, a pool which is called in the Hebrew tongue Bethesda, having five porches. In these lay a great multitude of impotent folk, of blind halt, withered, waiting for the moving of the water, &c." The central figure of the piece is a woman not of Jewish east, who sits in front of the pool, clasping to her breast a sick child whom she has brought to the healing waters. With pallid and dark complexion, her eyes uplifted in faith, tearful with a mother's emotion she is waiting anxiously for the angel to trouble the water. Her very hands seem to express the nervous anxiety with which she waits, and the bracelet round her wrist and the rotund arms are painted with remarkable realistic power. On her right side behind, crouches a dark old cripple eager for the first sign of movement of the pool, bent solely upon the material manifestation of signs, but whose face and beard are painted with life-like force. The artist has evidently attempted a contrast between these two prominent figures—the woman as typifying the Christian spirit, and the old cripple the Jewish Sadducean belief in "signs and wonders." He has, moreover, given a stirring picture of the spiritual meaning of the miracle portrayed. The other figures are accessory chiefly. On the left side of the Gentile woman, lies on his back an old man, while in the background through an open porch, are descending two others carrying a sick youth to the pool. In these also there is clearly a meaning conveyed that we cannot overlook. But the picture has an additional interest in the architectural background which represents one of the entrances or porches. The circular pillars are carefully delineated, and show a study of the best authorities, while upon one of the pillars we see hung several rows of straps, buckles, &c., or votive offerings symbolical of the infirmities cured. Upon this portion of the painting too much praise cannot be bestowed. It is not obtrusive in drawing or colour, the grey-coloured stonework of the pillars, the deepened shade of the gateway and the reflected lights, happily set off the figures and draperies, and these are subordinated to central figures, upon which a strong light is thrown. The pool itself, which occupies the extreme foreground, is transparent, and its reflections skilfully managed, while a white feather which floats lightly on its surface, helps to intensify the idea conveyed. We understand Mr. Long devoted much time to the water and its reflections, and actually modelled his figures and their draperies in order to obtain the true reflection. In composition and colouring the picture is a masterly performance without a painful sense of crowding; everything is subordinate to the dominant sentiment sought to be conveyed while the technique leaves nothing to be desired. We understand the picture is in the hands of the engraver and will shortly be reproduced.

COMPETITIONS.

IPSWICH POST-OFFICE.—It is satisfactory to note that the Town Council of Ipswich have decided to adopt the suggestion made in these columns a fortnight since, and will call in an architect to report upon the 22 plans received in competition for the new post-office and public offices.

RAMSGATE.—Mr. Abernethy, who was called in to advise on the plans of the proposed new road to connect the East and West Cliffs, delivered his report on Tuesday. He awarded the first premium to Mr. Cummings, of Tunbridge; the second to Mr. Higgins, of Victoria-street, Westminster; and the third to Mr. Trounson, of Penzance. The number of competitors was about seventy.

SCHOOLS OF ART.

NEWPORT.—A public meeting was held on Monday night to present the prizes for the past year to the students of the Newport (Mon.) School of Art. Mr. W. N. Johns read a short report for the session which closed last August. There were 70 students, being an increase of 22. The art day school was open 49 weeks, and was attended by six students. The number of drawings executed was 1,467, by 39 students. Nine passed in works, five in freehand, three in model, four in geometry, two in perspective, winning 23 certificates and two prizes. There were six in machine drawing, three in mathematics,

seven in acoustics, light, and heat; nine in magnetism and electricity; 20 certificates and five prizes. 1,552 works had been sent up for examination this year, and that accounted for the few drawings in the room.

Building Intelligence.

DERBY.—New beard-schools in Traffic-street were opened on Thursday, the 24th ult. These are the fourth erected by the Derby School Board, and have been erected from the designs of Messrs. Colthurst and Story, architects, Derby, which were selected in open competition. Accommodation is provided for 738 children. The boys' department comprises a principal school-room 54ft. by 22ft. by 20ft., and three class-rooms, each 23ft. by 20ft. by 15ft., the girls' department a principal schoolroom 48ft. by 22ft. by 20ft., and three class-rooms, each 22ft. by 20ft. by 15ft., and infants' department of similar size and arrangement to the girls. The infants are on the ground-floor, and the boys' and girls' on the first-floor, the space beneath the boys' room being formed into a covered playground. The rooms have double sashes, and are heated by hot-water. The style of the building is semi-Gothic, the outside is faced with best pressed red bricks with Stanton stone dressings and blue brick bands. The roofs are slated with Bangor slates and the ridges are finished with ornamental red cresting and terminals; on the centre of the main roof is a ventilating turret. The whole of the joiners' work is of selected pitch-pine, varnished. A boarded dado 4ft. high, with moulded capping, is carried round the whole of the rooms and corridors. Each yard is supplied with spacious latrines furnished with Macfarlane's patent iron fittings. The desks are on the dual principle, five rows deep, and were supplied by Messrs. Illingworth and Ingram, of Leeds. The contractor for the buildings was Mr. John Gilling, of London-road, Derby. The heating apparatus was supplied and fitted by Mr. T. Crump. Mr. R. Shepherd has acted as clerk of works. The total cost of the schools has been £6,700, including site £1,225, contract £4,300; and fittings, architect's commission, law costs, and extras, £1,275; the total cost being at the rate of £9 1s. 9d. per head.

ELY.—On Wednesday week St. Mary's Church, Ely, was reopened after restoration. The church has from time to time undergone repairs and alterations, but no great outlay was made for that purpose till 1829-30, when most of the stucco work and cement covering of the walls was done and pews and galleries erected. The first work recently undertaken was to examine the foundations, which for the most part were built upon the rock. These were found as sound as when first laid. The wall of the north aisle extending from the buttress at the east end of the base of the tower at the west end was in such a ruinous condition as to require rebuilding, the safety of the roof being dependent on this being done. The north porch bore evident traces of having been supported by external angle buttresses on each side of the entrance. These have not been rebuilt, but the windows which were bricked up have been reopened and glazed, and the old worn-out stone seats have been neatly re-topped with oak. On the side of the south aisle the stonework has been thoroughly repaired. The flank wall of the south chapel had to be entirely rebuilt, and a new external doorway has been inserted. The north clerestory wall has been repaired and relieved of its damp-looking coating of stucco. The nave roof was found in good condition; the roofs of the aisles were covered with lead, but so worn that the rafters were entirely decayed. The rafters had to be replaced, and the roofs are now covered with slate. The whole of the works have been carried out by Mr. Brown, builder, of Lynn, from the drawings and under the superintendence of Mr. Francy, of the firm of Messrs. Francy and Wood, architects, of Spring-gardens, London. The entire cost of the works amounts to £2,200.

HANWELL, MIDDLESEX.—The corner-stone of the new church, dedicated to St. Mark, was laid on the 25th ult., by Mr. Octavius Coope, M.P. for Middlesex. The first contract comprised the chancel, transepts, and first bay of the nave and aisles; since then the committee have been enabled to give orders for the

vestry and second bay of nave and aisles, and they trust before the works in hand are completed, sufficient funds will be forthcoming to complete remaining portions of the church, thus leaving only the tower and spire to a future period. The church is built of stock bricks, with stone and red brick dressings; the internal jambs and arches are red bricks, specially moulded with Pennant stone columns to nave and chancel. The roofs are of pitch-pine, plastered between rafters, covered with red tiles. The architect is Mr. Wm. White, F.S.A., of 30A, Wimpole-street, and the contractor of the whole of the works is Mr. Thomas Gregory, of Clapham-junction.

INCORPORATED CHURCH BUILDING SOCIETY.—The Incorporated Society for Promoting the Enlargement, Building, and Repairing of Churches and Chapels held its usual monthly meeting last week. Grants of money were made in aid of building new churches at Hulton View, Sambrosc, near Widnes, Lancashire, £200; Mottingham, in the parish of Eltham, Kent, £50; Sydenham St. Matthew, Kent, £150; Waen-fawr, in the parish of Llanbellig, near Carnarvon, £100; and Wigan St. Andrew, £300; rebuilding the churches at Hognaston, near Ashbourne, £70; Hopwas, near Tamworth, £90; Mansergh St. Peter, near Kirby Lonsdale, £60; and St. George, near Bristol, £200. Enlarging or otherwise improving the accommodation in churches at Broad Hinton, near Swindon, £30; Canterbury St. Dunstan, £40; Coldmore St. Michael, near Wallsall, £15; Cold Higham, near Towcester, £20; Cottingham St. Mary, near Rockingham, £20; Llangendcirne, near Kidwelly, £30; Pinhoe St. Michael, near Exeter, £20; and Prestbury St. Peter, near Macclesfield, £60. In consequence of the more extensive nature of the work, the grant of £170 formerly made towards building the church at Cambridge St. Barnabas was increased to £300. Grants were also made from the Special Mission Buildings Fund towards building mission churches at Axminster, Devon, £20; and Clayhanger, in the parish of Walsall Wood, Stafford, £30.

LANCASTER.—The town council have accepted the designs and tenders of Messrs. Handiside, for the erection of a new covered market. The building will cover an area of 154ft. by 150ft. The roof will consist of five bays, each 30ft. 6in. wide; these will be supported by 35 cast-iron columns, of an average height of 26ft. These will be placed longitudinally 25ft. apart, transversely 30ft. apart, connected by cast-iron framing.

LEICESTER.—On Wednesday week the memorial stone of the new chancel in course of erection at St. George's Church, Leicester, was laid. In connection with the new chancel there will be built an organ chamber, vestry, and chancel aisle. The chancel will be 32ft. long by 29ft. wide, the vestry 10ft. by 11ft., and the chancel aisle 20ft. by 12ft. The western gallery will be entirely removed, and seats for the choristers placed in the chancel. The altar will be elevated 4ft. 6in. above the nave floor, and immediately behind the former will be constructed an elaborate traceried seven-light eastern window 28ft. in height and 17ft. wide. The cost of the new chancel is estimated at about £3,500. Derby stone has been employed, and the appearance of the chancel, when erected, will harmonise with that of the church itself. The architect is Mr. A. W. Blomfield, Montague-square, London, and the work has been intrusted to Mr. Allen, Erskine-street, Leicester.

LICHFIELD.—The Dean and Chapter have issued an appeal for aid in filling in the 108 niches of the west front of Lichfield Cathedral, half of which is now in process of restoration. The work has been laid out in two sections, the north and the south. With the latter such progress has been made that its restoration already discloses the ultimate beauty of the whole façade. The Dean and Chapter estimate that each figure will cost £15, and whilst they will accept the choice of subscribers for a given statue, they reserve the right to select the sculptor and to regulate, for uniformity, other of the surrounding circumstances. At present the west window is surmounted by the figure of Charles II.; this will in future be occupied by a representation of our Saviour; whilst immediately beneath the niches will be filled with statues of the angels Raphael, Michael, and the Prophet Elijah. The line immediately beneath the parapet will include figures of Adam, Abel, Abraham, Isaac, Jacob, Seth, Enoch, Methuselah, Noah, Daniel,

Job, and Shem. The lines in the middle period (circa 1300 A.D., Bishop Langton) will include figures of Ezekiel, Hosea, Jonah, Zephaniah, the angel Michael, St. Stephen, Bishop de Chinton, Bishop Patteshull, Bishop Langton; the next line Daniel, Joel, Micah, Haggaai, the angel Raphael, St. Nicholas, Bishop Hacket, Bishop Lensdale, and Bishop Selwyn. The present figures will give place to St. Chad (which will occupy the centre position immediately above the west door), the figures to the north being in the following order:—Penda, Wulfere, Etheldred, Offa, Egbert, Ethelwolf, Ethelbert, Ethelred, Alfred, Edward the Elder, Canute, and Edward the Confessor. The lower line will include the statues of St. Paul, St. John, St. James, St. Simon, St. James the Less, St. Jude, and St. Matthias.

LITTLE SHELFORD, CAMBS.—The parish church of All Saints was reopened on Thursday, the 24th inst., after restoration from the designs of Mr. R. Reynolds Rowe, F.S.A., of Cambridge. The whole fabric has been underdrained, and one of Porritt's underground stoves has been fixed in the nave. The wretched work of 1760 in the chancel has been cleared away, and the sanctuary rebuilt; portions of stone coffins, and fragments of the earlier fabrics of 1080 and 1308, found in the walls, being worked upon so as to be exposed to view. The chancel is made to harmonise with the work of 1308, rather than with the additions of 1450. It is now entirely cased on the exterior with flints and pebbles, and the interior lined with Ancaster and Clunch ashlar work. The steps levelled by Will Downing in 1643 have been restored, new wood floors have been laid under the seats, and pavements of stone and tiles have been laid in other parts, those for the sanctuary being copies of the old figured ones found in the church. Old pews have been cleared away, the nave re-seated in oak, and the Jacobean pulpit cleansed, repaired, and set on a stone base. The walls of the nave have been repaired, made as upright as possible, and plastered inside. New roofs, copies in fac-simile of the best parts of the old ones, have been placed over the nave and chancel. They have cambered oak tie-beams and king posts; the ceilings are boarded and divided into panels with the old bratticing, ribs, and paterae; the roofs are recovered with the old tiles. The lower stages of the buttresses of the tower have been rebuilt. The south doorway has been renewed in moulded stone, a new oak door has been provided, and the whole protected by a porch of oak upon a stone plinth. It was intended to add a north aisle and to restore the tower, but at present these schemes have not been carried out for want of funds.

METROPOLITAN BOARD OF WORKS.—At this board on Friday, a letter was received from Sir H. A. Hunt, transmitting a copy of his final award in connection with the Great Wild-street Improvement Scheme, under the Artisans' Dwellings Act, 1875; it was referred to the Works Committee, to whom also was sent communications from the Home Office, transmitting copies of the provisional orders and plans relating to the Little Cornam-street, St. Giles and St. Pancras; West-street, Poplar, and Great Peter-street, Westminster, Improvement Schemes under the same Act. To the same committee was also forwarded a letter from the Home Office with reference to certain "Model Dwellings" now being built in Bethnal Green parish, which the local vestry fear will prove unhealthy, although they comply with the requirements of the Metropolitan Building Acts.

PRESTON BAGOT.—The parish church of Preston Bagot, near Henley-in-Arden, was reopened on Friday week by the Bishop of the Diocese. The restoration of the church has been carried out under the direction of Mr. J. A. Chatwin, of Birmingham. As the east end had to be taken down, by order of the diocesan surveyor, the architect took advantage of this, by extending the chancel a few yards, and erecting a chancel arch. The old east windows have been inserted in the new walls. In place of the red-brick chamber at the west end, for the bells, a turret, in character with the building has been erected. The old south porch was falling into decay, and has been replaced by a new open porch of English oak. Two small Norman lights in the north wall are to be filled with glass, by Messrs. Hardman. The work has been done by Messrs. Smallwood and Co., of Wootton Waven. The carving was executed by Mr. Roddis. Messrs. Jones and

Willis made the altar-cloth and dossal, and the lamps which are suspended from the roof.

TEDDINGTON.—The new cemetery was consecrated on the 9th of April. The whole plot of ground is nine acres, five and a half of which is laid out for present use, divided by a path 18ft. wide, one part consecrated and one part unconsecrated ground, all being laid out in flowing curves. The two chapels are of the Fourteenth Century Gothic, good in design, and connected by a carriage way over the central path and entrance arch flanked by towers, a vestry in each tower, surmounted by octagon crocketed spires; the chapels are each 30ft. by 20ft. inside, lined with white bricks and relief stamped Minton tiles. The material used for walling is Bargate ragstone, from Godalming, and Box Ground Bathstone for dressing. The contractors were Messrs. Harris and Borell, of Teddington. The carving, which is very satisfactory, is by Bide Szymanowicz, of Westminster, and the whole has been carried out from the designs and under the superintendence of Mr. T. Goodchild, architect, Adelphi, London.

THORPEBASSETT.—The parish church of Thorpebasset, in the East Riding of Yorkshire, which since July last has been undergoing a thorough restoration, was one of the type of plainness and solidity characteristic of the Early period of Norman architecture now fast disappearing. The edifice, though plain and unpretending, was full of interest, and we are glad to learn that its best features have been preserved in the present restoration, which was necessitated by the dilapidated condition of the building. The old piers and arches which were blocked up in the north wall have been opened out. A vestry has been added, separated from the north aisle and chancel by two arches, and spanned by a plain oak screen. The east and west walls retain their original character, but the higher elevation of the new roof has necessitated the reconstruction of the bell tower. The roof is now of one uniform level from east to west, and the main portion is covered with grey Westmoreland slates, the north aisle (the only one) being covered with lead. A new porch has also been added, of open woodwork, on a stone base; a much-needed protection to the fine old Norman doorway, which has survived many restorations of the church. All the windows in the north and south aisles are new. The architects are Messrs Paley and Austin, of Lancaster; and the contractor is Mr. Brown, of York. The church will be opened in June.

YARM.—The church of St. Mary Magdalene, Yarm, was reopened last week after restoration, under the direction of Messrs. Alexander and Henman, of Stockton-on-Tees. No structural alterations have been made in the building, but the interior has been thoroughly renovated; the floor has been raised and laid with wood blocks, and tiles in concrete and oak benches with covered ends now form the seating. The chancel, which before was very cramped, has been brought forward one bay into the nave, and divided from the south aisle by a carved oak screen, and on the other by the organ. Several new stained-glass windows have been inserted. New polished brass gasfittings have been supplied, and instead of the yellow wash, which formerly disfigured the walls, piers, and arches, decoration in colour has been carried out. The ceiling, formerly of plaster, is now in moulded and panelled pitch-pine. Messrs. Craggs and Benson, of Stockton, were the contractors for the bulk of the work. The total cost of the alterations amounted to about £2,500.

The Yorkshire Fine Art and Industrial Exhibition will be opened at York on Wednesday next, the 7th inst., by the Archbishop of York.

Four groups of statues in Caen stone have just been placed in St. Walburge's Roman Catholic church, Preston. The two are placed on the right and left of the high altar, and represent Adam and Eve after the fall, and Noah, the restorer, leaving the ark. The other statues represent Moses and Aaron, and are placed on either side of St. Joseph's altar. They are the work of the German sculptor, W. Pfyffer, and have been refurbished by Mr. Park, a local artistic decorator. In the centre of the high altar has been placed another statue, the Lamb of the Apocalypse, which had been carved from one piece of Caen stone, by Mr. Sherratt, of Preston. A stained glass window has been placed in the church by Lady Holland, in memory of her late husband. In the centre light is St. Henry, and on either side Saints Catherine and Cecilia.

More than Fifty Thousand Replies and letters on subjects of Universal Interest have appeared during the last ten years in the **ENGLISH MECHANIC AND WORLD OF SCIENCE**, most of them from the pens of the leading Scientific and Technical Authorities of the day. Thousands of original articles and scientific papers, and countless receipts and wrinkles embracing almost every subject on which it is possible to desire information have also appeared during the same period. The earliest and most accurate information respecting all new scientific discoveries and mechanical inventions is to be found in its pages, and its large circulation renders it the best medium for all advertisers who wish their announcements to be brought under the notice of manufacturers, mechanics, scientific workers, and amateurs. Price Two-pence, of all book-sellers and news-vendors. Post free 2½d. Office: 31, Tavistock street, Covent-garden W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements and Paragraph Advertisements is, per line. No front page or paragraph advertisement inserted for less than 5s.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 33f. 30c.). To India (via Southampton), £1 6s. 6d. To any of the Australian Colonies New Zealand, the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

N.B.—American and Belgian subscribers are requested to remit their subscriptions by International P.O.O., and to advise the publisher of the date and amount of their remittance. If the last-mentioned precaution is omitted some difficulty is very likely to arise in obtaining the amount. Back numbers can only be sent at the rate of 7d. each, the postage charged being 3d. per copy. All foreign subscriptions, unaccompanied by an additional remittance to cover the extra cost of forwarding back numbers, are commenced from the next number published after the receipt of the subscription.

Cases for binding the half-yearly volumes, 2s. each.

RECEIVED.—P. S. B.—H. W.—F. W. and Co.—M.—J. W. G.—B. S. B.—A. P. Co.—A. J.—A. W. R.—J. H.—T. H. C.—E. S. and Co.—W. T. and Sons.—C. of G.—F. J. B.—B.—F. W. and Co.—R. Bros.

J. P. HIGGINS. (The company which supplied the patent siliceous stone referred to was wound up some time since. We do not know who supplies it now. We should advise you to paint the verandah with the silicate paint made by the Silicate Paint Company, Charlton, Kent.)—R. B. HESLOP. (The same—simply different modes of spelling.)—OUR or TOWN. (Rivington's, Waterloo-place. Why not consult advertisement pages.)

"BUILDING NEWS" DESIGNING CLUB.

F. R. (We return the designs after our review is written.)—C. J. CALVERT. (The subjects will be announced in due course. We have noted your motto.)—B. C. (We, of course, intended the fire-place opening to be 3ft., but the treatment we leave to competitors. The misprint as to scale was corrected. It is a 1-6th of an inch scale.)

Correspondence.

HALIFAX SCHOOL BOARD COMPETITION.

To the Editor of the BUILDING NEWS.

SIR,—It having been stated in your columns that, acting upon Mr. Robson's report, the Board have decided to accept none of the plans sent in, it ought to be known in justice to the 93 competitors that Mr. Robson was only allowed to see a few of the designs submitted, chosen from the others by the Committee.

The fact that in those selected by the Committee none were worthy, in Mr. Robson's opinion, of being carried into execution, is a much greater reflection upon the wisdom of the Committee than upon the ability of the 93 architects who wasted their time in the competition.

If Mr. Robson had been allowed to inspect the whole of the designs none of the competitors could have complained.

In brief, the history of the whole affair is this:—

The Committee, whose duty it was to report upon the designs sent in, met, and with wonderful rapidity selected 7 designs out of the 93 (all the 7, by the way, being by local men). Of the 7, this remarkable Committee placed one of the designs first, one second, and one third. Then,

strange to say, all the sealed envelopes were opened, and everything made known before the monthly meeting of the Board, which was to endorse or otherwise the action of the Committee.

At the Board Meeting, the selection of the Committee was considered most unsatisfactory, and was not formally sanctioned. The full Board resolved itself into Committee, and selecting another set of 7 designs, called in Mr. Robson to report upon the 14.

How marvellous and intricate are the actions of committees!

Before Mr. Robson arrived at Halifax, the unfortunate 79 designs (none of which were to the Committee's thinking worthy a glance of Mr. Robson's eye) were returned to their still more unfortunate authors, many of whom were well up in Board School designs, and some of whose designs for this competition were much admired by authorities on School Board building perhaps as high as the Halifax Committee.—I am, &c.,
SET SQUARE.

WESLEYAN CHAPEL COMPETITION, SWINDON.

SIR,—I will not attempt to answer the pertinent question of your correspondent, "A Lover of Justice," but with your permission will give him a few additional particulars, which, as far as I can learn, are quite correct.

The committee, when reviewing the plans in a public journal, stated that they had selected some half-dozen from those sent in subject to the crucial test of an estimate, and if the first exceeded the stipulated sum they should take the second, and so on. The sequel, however, proves that after obtaining an estimate of the first, and finding it would cost nearly £5,000, they communicated with the author, who replied that he would guarantee it to be carried out within 10 per cent. of the stipulated sum. The committee met him, and the result was that tenders were publicly advertised for, the quantities being supplied to builders, and the highest estimate sent in for the works was £4,781 and the lowest £4,000. After several meetings of the committee, at which the said architect was present, they decided to accept his plans. About three months from the date the plans were first sent in the unsuccessful ones were returned, with a note stating the decision of the committee.—I am, &c.,
ONE OF THE UNSUCCESSFUL ONES.

BUILDING MACHINERY.

SIR,—We notice your article in the BUILDING NEWS of April 18th, "Notes on Building Construction Materials," and beg to say we have a revolving scoop, a tool corresponding, if not exactly, very nearly, to what you describe, and herewith inclose you list. The advantages of the use of this implement are not fully understood. For use in digging cellars and for the general purpose of removing earth expeditiously this implement is indispensable. If in making roads the plough and scraper were used together in breaking up and removing the soft top-soil, and then with the scraper the hard subsoil was formed into a slightly rounded carriage-way, a hard and firm foundation would be secured.

We find more difficulty to introduce scrapers into this country than anywhere else, and it seems a pity no trials or shows are held, from time to time, of building machinery; and we consider it would be to the interest of the building trade if you would develop the idea.—I am, &c.,
SELIG SONNENTHAL.

RAMSGATE PROPOSED NEW ROAD DESIGNS.

SIR,—I observe it is reported in your last number that the Ramsgate Improvement Commissioners have instructed Mr. Abernethy, C.E., to adjudicate on the respective merit of the competitive designs for the new road.

When first I heard that this gentleman was the person proposed to be selected I was much disappointed, as I am certain from his connection with the town on former occasions his judgment will not give such general satisfaction among competitors as that of an entire stranger. Since then I have heard my opinion confirmed by several competitors.

On reading Mr. Abernethy's letter, read at the last meeting of the Improvement Commissioners, I was more than ever convinced that his appointment will be most unsatisfactory. I will now

give the points of Mr. A.'s letter bearing out my statement. He says—

"I do not compete in designing. My son applied for plans and conditions simply to enable us to ascertain how the scheme might affect the question of extending the London, Chatham, and Dover Railway through the town, &c., &c. . . . a matter of great importance to the future prosperity of the town, and in which I am personally interested. . . . This project ought not to be lost sight of in connection with the new road, and it ought to be revived," &c., &c.

Now, is it not perfectly clear that the designs which fit in best with Mr. Abernethy's scheme of a railway extension will be successful ones, and the rest nowhere?

Is it likely that the best scheme of the lot—best for the town—best as an engineering work—best economically—and best for convenience—would stand a chance for first premium if it did not directly or indirectly favour—or rather if it happened to be antagonistic to Mr. Abernethy's railway scheme?

I will not trespass further on your space than to reiterate Mr. Abernethy's words referring to his railway scheme. He says it is "a matter in which I am personally interested, and which ought not to be lost sight of in connection with the new road." Now, how can a judge so situated give an unbiased judgment?—I am, &c.,
A COMPETITOR WHO PROTESTS.

THE CARLIOL TOWER, NEWCASTLE-UPON-TYNE.

SIR,—In the report given in your journal of the 25th inst., on the inquiry held by Mr. C. J. Smith with reference to the erection of a Central Free Library, statements are made by Mr. Oliver "in regard to his plan that it is only a clerical error," that "he got the position of the tower from one of the surveyors," and concerning "Mr. Fowler himself having made a mistake of some £10,000." These assertions being widely circulated through your journal, have a tendency to mislead the public if not corrected. I, therefore, have to state, with your kind permission, that the plans and drawings prepared by Mr. Oliver show on the north side a space behind the tower 20ft. in width, the actual width being only 10ft. 8in.; and upon this supposed 20ft. space Mr. Oliver shows a gallery of casts, art rooms, &c., which forms the only means of communication with the proposed building and the Mechanics' Institute. The remainder of the north boundary of the site Mr. Oliver shows 4ft. wider than available. The perspective is also incorrect. The new tower, instead of coming forward as shown, will scarcely be seen; and if carried out according to the ground plan will cut some feet into the old Weavers' Tower.

The drawings are drawn to scale, and have been exhibited in the public reading-room and art gallery here, placed in juxtaposition with my design.

Information has not been given by any of the Corporation surveyors, and the position of the tower is correctly shown on the large scale Ordnance Survey plans, therefore I am at a loss to know who "one of the surveyors" can mean.

I have not made a mistake in my estimate (which statement several members of Council and myself contradicted at the meeting); but, on the contrary, the stated amount of £20,000 I gave as the total cost of the scheme complete I consider to be a safe practical estimate, inasmuch as the lowest tender for the first contract for the shell of the building now on approval pending this inquiry amounts to £10,619 18s., and is under my estimate for this portion of the work. Other contracts will follow. To these must be added the purchase of the site of the tower, and belonging to the Corporation Estate (which must be allowed for), and the amount to be paid for the Mechanics' Institute, all of which items, showing how the £20,000 is made up, were handed to Mr. Smith. Mr. Oliver's assertion is, therefore, untrue. I will leave those best able to form an opinion as to whether or not such grave errors over a small strip of land made on plans and drawings for the purpose of soliciting public patronage can be considered clerical.—I am, &c.,
ALFRED M. FOWLER, M. Inst. C.E.,
Borough Engineer and Town Surveyor.

Borough Engineer and Town Surveyor's Office, Town Hall, Newcastle-upon-Tyne, 29th April.

CREOSOTED TIMBER.

SIR,—Will you kindly allow us to make a brief reference to the report of an inquest contained in your issue of the 18th inst.? To some extent your article on page 427 of the same paper is a reply to the extraordinary evidence of the district surveyor, whose statements we may say are in direct opposition to the experience and testimony of many of our most eminent engineers who have had ample opportunity of forming a correct judgment.

It does not appear to have occurred to the jury that the piece of timber in question might have been rotten at the heart when creosoted. Any person accustomed to cutting up timber knows that instances are constantly occurring of balks turning out rotten which before being cut had every appearance of being perfectly sound. It is rather amusing to be told that "the process of creosoting is a failure." We thought it had been pretty well established that when properly performed no process is so effectual, and none has so successfully stood the test under all kinds of circumstances which usually induce decay. We have known timber creosoted while quite wet—or rather we should say that the attempt has been made to creosote it—and we have also known it merely brushed over with creosote instead of being properly subjected to pressure under steam power. In either case the process would be almost useless.

Our experience as creosoters extends over twenty-six years, and such is our confidence in the thorough preservation of timber prepared by us that we have never hesitated to engage to replace at our own cost any wood that might be found to have decayed, provided that the surface, which contains the denser, and therefore the more valuable, portion of the preservative, had not been disturbed.

You have referred to the experience of Mr. Harrison, chief engineer to the North-Eastern Railway Company, relating to creosoted sleepers which had been in use for twenty years. More recently some Scotch fir sleepers have been taken up for examination from the same railway which have been in use for twenty-seven years, with a very heavy traffic over them, and they are still in a perfectly sound condition. Unpreserved Scotch fir sleepers have frequently to be renewed in three to six years. We send you a piece of one of these creosoted sleepers.

For tramway construction purposes some creosoted beech pavement has just been taken from the carriage-way of the bridge at Sunderland. This we supplied to the Corporation twelve years ago. It has been in constant use during this time, and is now perfectly sound, and practically as good as when first laid down. It would be difficult to find a more severe test of the value of a preservative. In its natural state scarcely any wood decays more rapidly than beech when exposed to wet and dry weather. Unpreserved, this pavement would not have lasted one-fourth of the time.

We will not trespass further on your space, but will be glad to furnish to any of your readers further information as to creosoting, and ample testimony as to its value.—We are, &c.,
ARMSTRONG, ADDISON, & Co.

North and South Docks, Sunderland,
and Northumberland Dock, near
North Shields.

The Hackney Board of Guardians have obtained the qualified approval of the Local Government Board to the erection of one of four proposed portions in connection with the scheme of extending the workhouse infirmary accommodation by building on the Castle-house estate. In returning the plans of Messrs. Lee and Smith, the architects to the Guardians, the Local Government Board recommend the area of window space in an infirmary should not be in greater proportion than a rate of 1 foot super to every 70 feet of cubic space in the ward; and intimate that windows should be arranged to be about 12 feet from centre to centre, and carried up to the ceiling, or to within 12 inches of the height of the ceiling, could probably be proportioned to meet this demand. The Board also require small wards containing three or four beds to be provided for special cases.

The spring exhibition of modern paintings has been opened at Southport. Amongst the water-colours are "At St. Peter's, Castello, Venice," by T. Hampson Jones; "Old Buildings at Newton, Shropshire," by William Eden; "Market Morning, Place St. Pierre, Lisieux," by Samuel J. Hodson, and "St. Hilda's Abbey, Whitby," by Walter Crane.

Intercommunication.

QUESTIONS.

[5751].—**Board School Plans.**—In submitting plans, &c., of board schools to the Education Department for their approval, is it necessary they should be accompanied by the specifications and bills of quantities? I am a novice in this matter, my present job being the first of the kind, and I should be thankful to receive from you an explanation of the requirements of the department relative thereto—viz., the deposit of plans. I have prepared a set of plans and specifications, and my board is pushing me to get them passed so that we may commence building, but I have not yet got out the quantities.—R. T.

[5752].—**Staining and Polishing Church Seats.**—I have a lot of deal church seating to do, and I want to give it a slight stain and a good dull polish. Will some one tell me how to do this, and the probable cost per yard? Super varnish is objected to as it makes it look so common.—V.

[5753].—**Abutments.**—Will one of your correspondents kindly work out in plain figures Spon's rule for the thickness of abutments—namely,

$$T = \sqrt{\frac{1}{2} L^2 + \frac{3}{2} B^2} + \left(\frac{W}{H} \right)^2 - \frac{W}{H}$$

Also the rules for struts and braces—namely,

$$D = \sqrt{L^2 + 2} \times 0.8.$$

—ALT BELCHER.

[5754].—**Drainage.**—I have been asked to prepare plans for the sewerage of a millage containing about 8,000 of a population, and would be glad if any of your experienced readers would kindly give me a few hints as to proportioning sizes of main, and branch pipes. The area of surface water drainage to be provided for, and how the varying gradients of drains enter into the calculations for determining the various sizes of the pipes? Also if there is any Act preventing the adjoining stream receiving the sewerage? Any hints on a small and suitable scheme will be much valued by me.—A LOCAL SURVEYOR.

[5755].—**House Details.**—I am having a house built, and most unfortunately my architect died, when some differences arose with the builder. Will some of your many readers give me their opinion on the following points. 1st. The outer walls are 2ft. 1in. thick, being 1ft. 6in. stone on the outside, 2in. cavity, and 4in. brick inside. Strips of lead are specified to be built in over all openings. What width ought they to be, and what is the proper mode of fixing? Show by sketch. 2nd. A "25-gallon copper" is specified for the washhouse. What is a copper? Is it made of iron or copper? The builder says the former and I the latter. Which is right?—VICIUM.

[5756].—**Black Colour on Stone.**—The stone we are using on a public works in the north is quarried from rock situated in the coal-measures and apparently contains iron. After being dressed and set it grows black in a few months. Can any one tell me how to take away this objectionable feature and restore the stone to the original light colour?—AN OLD RESTORER.

REPLIES.

[5759].—**Perspective.**—Draftsmen adopt their own methods as to heights. Some never think of taking any further trouble in the matter than arranging the heights by the eye. Of course, the proper method is to set them off on the edge of the picture plane, though I have generally fixed them at some convenient position at the side of my drawing, determinable, of course, by the width of interior. It is necessary in ordinary cases of drawing interior perspectives, to assume a station point beyond the interior, and if any size is to be given to the view this necessitates an enlargement.—G. H. G.

[5713].—**Wood Worms.**—Place the furniture in a closet or small room, and fumigate thoroughly with benzine. Chloroform has also been used with success, but benzine is more penetrative. The closet should be made airtight and the benzine renewed at intervals for a few days. Vapourisation has been found effective in many cases.—G. H. G.

[5715].—**Staybars v. Stained Glass.**—The queries raised by "Architect" are suggestive if not useful. I quite agree with him that the iron "staybars," or, as I have always called them, "saddle-bars," of old windows should not be disturbed, but that the stained glass should be made to suit them. Why should the architectural features of a building be destroyed or injured by painted glass? Is it not, indeed, preserving a proper relation between architecture and painted decoration to retain all structural expedients? Unfortunately, architects and stained-glass artists will continue to disagree upon this point, but I certainly could never understand the taking down of old ironwork to windows—perhaps extremely interesting specimens—to introduce, it may be, stained glass figure subjects, a proceeding not necessary if the glass artist at all cared for the ironwork. The plugging of the wire netting has injured and shaken the stone mullions and tracery of many fine windows, and I remember a case in Hampshire in which a fine perpendicular chancel window was taken out simply because it was found too old to bear the introduction of a memorial window without iron supports, and a new window—a miserable copy of the old one—was substituted. I certainly think this kind of tampering one which architects should resist, and that old windows had better be left alone or filled with geometrical designs rather than the ironwork should be interfered with.—G. H. G.

[5726].—**Rolled Joists.**—ERRATUM.—Last week's reply does not yet read correctly. It should read "W = breaking weight in tons on the centre."—H. A.

[5728].—**Coloured Building Stone.**—Has not Mr. Trickett fallen into the same error as "G. H. G.," and somewhat overdone the matter? It is not a long list of "names" we want, but some examples that our eyes may behold and see for ourselves and form our own opinions. For instance, the "Haul in Hand" is a good example in red; but what is it, and where does it come from? These

are the sort of questions to be answered. Apropos of red stone, I note in my peregrinations in and about town that some red stones bleach or lose their colour, and are afterwards paid over with a pigment of some kind which gives them a dirty chocolate brown colour, notably some large cantilevers at some red-brick mansions near Gloucester-road station; and then I note, also, that the Mansfield columns in the south facade of the Law Courts are of two shades, while those on the east front are much darker in colour than either. Can Mr. Trickett or any other correspondent explain this?—J. W.

[5741].—**Shop Front Work.**—I should advise "Constant Reader" to erect his building on the front girder before putting in the iron column, and allow the building to deflect, then fix the column in position, and wedge up. If he puts in the column first and builds above it, the building will deflect on each side (the column not deflecting same as brick or stone pillars on which the girder rests at each end) thereby causing the brickwork above to crack right up the centre. I have just carried out a similar case and all above the girder is quite perfect.—D.

[5742].—**Drainage.**—I think I can give "A. C." some information on the subject. A local authority is certainly not bound to bring a drain to the limit of an owner's premises, but the owner would pay for the expense of the drain and the connection of same with the sewer. By the Public Health Act (1875) it is not lawful to erect a house, or to occupy a house newly-erected or rebuilt, until a covered drain or drains be constructed of such size and materials, and at such level and with such fall, as on the report of the surveyor may appear to the urban authority to be necessary for the effectual drainage of such house; and the drain or drains so to be constructed shall empty into any sewer which the urban authority are entitled to use, and which is within 100ft. of some part of the site of the house.—W. G. LOWER.

[5745].—**Wood Roofs.**—In reply to "Nil Desperandum" a reliable formulae for the scantlings for timbers of wood roofs will give results bearing no evidence of uniform analogy with the sectional areas which, according to the known strength of timber in tension, would be equivalent to the strains due to the weight of roof and calculated by the parallelogram of forces. Iron tie rods of, say, 1 1/2 in. diameter, will usually be sufficient where a sectional area of 60 or 70 in. in timber would be used, while about 6 or 7 in. would be equal in tensile strength to the tie-rod. The necessity for so great difference in excess arises from several causes. First the timber may be reduced to about one-half in area for strength by some great knot. Then, again, there may be a diagonal shake running half way through, and which may not be readily visible until the weather has seasoned the truss when fixed. Again, the mortises and bolt holes will perhaps reduce to two-thirds the available sectional area. And thick snow, when saturated with water—say, 12 in. thick and weighing as it would, about 40 lb. to the cube foot, would perhaps quadruple the strain; and screwing or keying a truss will place it under a very great strain, because the tie-beam will be much cambered, but which is a mistake, because the shrinkage of the timber will not alter the distance between abutments; and with respect to the keys, if the tie beam shrinks the joint between the king-post and tie-beam will open in any case. And again, the tie-beam is frequently utilised to carry the ceiling and should be substantial to fix to. All the preceding considerations render it likely that wood tie-beams are not usually made much too large, when about ten times the area demanded by the strain of roof-covering and timbers, especially when we consider that the wind may add 20 or 30 cwt. more per square on the roof. Let us take the case of a principal rafter—say, 18 ft. long. Treat it as a post, and consider that its scantling must increase as the square of the length. We shall use the following formula:— $W = 20 \frac{B \times T^3}{L^2}$ where 20 is a constant. W = ten times the safe load and consequently equal to the breaking load taken in cwt.

B = breadth in inches.

T = thickness in inches.

L = length in feet.

Say we have a possible pressure of two tons, then we take $10 \times 2 = 20 = W$. $20 = 20 \times \frac{B \times T^3}{205}$. $205 = B \times T^3$.

Let T = 4 and $205 \div 64 = 3.2$, say, 4 1/4 in., and therefore scantling will be 4 1/4 in. \times 4 in., and add 4 in. \times 1 1/2 in. for notching, abutments, and mortises, and we shall obtain 6 in. \times 4 in., which is about what is usually adopted. The constant 20 on the second side of the equation represents the supposed number of cwt. which would crush an inch cube of fir, although some red fir would not crush with less than 40 to 45 cwt. an inch cube, but some white fir might not bear more than 17 or 18 cwt. on an inch cube. Straining beams can be calculated by the same method. An inspection of the formula will enable us to see that our unit for compressible timber is really a piece a foot long by 1 in. square. Tie-beams will require increasing or diminishing in direct ratio to their length. If the length doubles, the sectional area requires to be doubled. If the length is halved then the sectional area should also be halved. King and queen posts should follow the same rule, and so in proportion, having a tie-beam determined for one span, we can easily find one for any other span, and, as the large spans are the most important, it would be best to recollect the safe scantling for a tie-beam of, say, 60 ft. span, and obtain others as required. We might assume a scantling known by experience to be trustworthy for 60 ft. span—say, 12 in. \times 10 in. Having found the sectional area we can easily dispose or modify it to suit the other timbers as to convenience in framing truss. King posts and queen posts can be made half the sectional area of the tie-beam. Small queens half the sectional area of the large queens. Braces or struts may be calculated by making their sectional area equal to one fourth of the length of strut in inches. The preceding supposes the pitch to be about 30 degrees and the trusses about 10 ft. apart, but a much more depressed pitch would increase the strain in proportion on the principal timbers. When the tie-beam has to be scarfed the full sectional area must be retained by bolted and indented iron plates over joints and scarfs. Purlins are not affected by the span of roof but only by their distance apart and length between proper supports, and should be calculated by the same methods as beams or hinders to support joists except that they only need to support about 4 cwt. per foot super as a safe load, or 2 cwt. as the breaking load on each foot superficial of roof plane.—HENRY ASHMOSE.

[5745].—**Wood Roofs.**—In wooden roofs the scantlings are generally in excess of the resistance, and seldom require to be calculated like iron. Thus, for example, the compression in the principals and struts is generally more than safely resisted by the usual scantlings allowed to prevent sagging between points of support. To calculate the sizes for a certain strain, compressible or tensile, divide the strain in tons by the number of tons per square inch the material will safely bear, the quotient will give net sectional area in square inches.—G. H. G.

[5749].—**Quantities.**—"A. B. O." has certainly a claim for the quantities he prepared and which have been used to obtain tenders, but he ought not to have parted with a copy to his client, who clearly wished to save the 2 1/2 per cent. It is a very unusual way of acting.—G. H. G.

[5750].—**Litigation.**—Of course, if "A Young Architect" gave a certificate and a balance is due to builder, he can only support his decision, as the board are acting in defiance of their professional adviser. "A Y. A." asks if there are any instances where architects appear in court against their clients and in favour of the builder. I do not remember at the moment any; but justice in such an instance has to be considered, not precedent.—G. H. G.

WATER SUPPLY AND SANITARY MATTERS.

DORKING AND LEATHERHEAD.—A Local Government Board inquiry was held on Friday before Mr. Arnold Taylor into an application from the Dorking rural sanitary authority that a portion of the parish of Dorking and all or some portion of Leatherhead should be formed into a united district for carrying out a system of sewerage. It was stated that both the towns were in urgent need of drainage, and that the line of the river Mole passing through both was the only practicable course for a system depending upon gravitation. It appeared that at present no engineering advice or scheme could be submitted, and that it was not proposed to take in the sewage of the intermediate village of Mickleham. The inspector expressed an opinion that this village should be included in any scheme, and pointed out that before further action could be taken the portion of Leatherhead to be included in the district should be defined.

DORCHESTER.—The Town Council have accepted the tender of Messrs. Bull and Sons, for the iron-work for an elevated reservoir at the waterworks, for the sum of £1,395; also the same firm's tender for the brickwork, &c., at £1,171. The tender has also been accepted of the Coalbrookdale Company for the engine and pump, for the sum of £1,890. The works are to be carried out under the superintendence and from the designs of Mr. W. Norman, the Borough engineer and surveyor.

STATUES, MEMORIALS, &c.

MR. GLADSTONE.—**MANCHESTER.**—A life-size statue of Mr. Gladstone, lately executed by Mr. Theed, forming a companion statue to those of Mr. John Bright and Mr. Villiers, has just been placed in the Manchester Town Hall. It occupies what may be considered the post of honour—namely, the central niche in the public hall, between the principal entrance doors. The right hon. gentleman is represented as addressing an assembly. The attitude is perfectly characteristic, and the likeness is said to be excellent.

LEGAL INTELLIGENCE.

UNSTAMPED DRAWINGS.—At the Leyburn (Yorks.) County Court last week, before Mr. E. R. Turner, judge, Richard Crabtree, plumber and glazier, Huxton, sued the Huxton and Arrathorne School Board for £1 16s. 6d. for work done during the erection of a new school. Mr. Teale, Leyburn, appeared for the defendants. Mr. Palliser, architect, Northallerton, produced the plans and specification. His Honour found specification stamped, but plans not so, and as they were not attached, he ruled that the plans required a stamp as well as the specification. Plaintiff was unwilling to pay the penalty and have the plans stamped, and his Honour nonsuited him with costs.

Before commencing his sermon on Sunday morning, the Rector of Haworth (the Rev. J. Wade, M.A.) said, with reference to what had recently appeared with regard to the rebuilding of the church, that his duty in the parish was not to keep a show place for strangers, but a house of prayer. This he should endeavour to keep steadily in mind. He had received from the Rev. Mr. Nicholls, who was the husband, and, as far as he knew, the only living relative of Charlotte Brontë, his entire approval of what was proposed to be done. When the new church was completed, it would raise some splendid memorial to the memory of that gifted family.

A new drapery establishment in George-street and Cheapside, Luton, was opened last week. The premises include shops, and show and workrooms. The style of the building is Italian. Messrs. Brown and Humphries are the architects, Messrs. Rayment and Sons, of Hertford, the contractors, Mr. Bann, foreman.

Our Office Table.

A VERY melancholy result of wholesale poisoning by sewage gas was revealed at an inquest held at Chelsea, last week, touching the death of a child. It appeared that on the day the child died five other children of the family and the mother were also attacked with similar symptoms, three of whom succumbed, while the mother and daughter still remain in a critical state. The medical evidence showed that death was caused by sewage poisoning, the drains of the habitation being in a most neglected condition, and the jury returned a verdict to that effect, at the same time strongly censuring the owners of the property for not keeping the drains in better order.

PROFESSOR PEARSON presided on Saturday at the award of certificates to successful students at the Crystal Palace Company's School of Practical Engineering. The three first on the list of successful first-year students in the examination on steam were T. Cargill, H. A. Marshall, and M. Wilson. For the drawing office, R. Laing and M. Wilson were bracketed equal first. There were certificates for 14 in the pattern shops, and 14 in the fitting shops. The three first certificated members of the civil engineering section, second year, were—first term, W. Halfhide, A. A. Barnes, and W. N. Woods; second term, R. L. McLaren, R. E. M. Labarea and M. F. Wilson (equal); third term, T. E. P. Gardner and G. T. Ogilvie (equal). After the distribution of certificates, Professor Pearson expressed his pleasure at finding that the study of engineering was now being cultivated in undiminished schools in England. It was once remarked by one who was not an engineer that the engineering profession was one in which a man sometimes succeeded without education; and to this the educated engineer replied, "But you do not know the heavy costs which are paid for the blunders of the uneducated engineer." The English race, by reason of inherent energy of character, was a race well fitted for the work of engineering, and its sons had had to grasp some of the greatest problems of engineering. The history of engineering, however, showed that some men of the highest capacity in the profession, through the fault of being imperfectly trained by only being acquainted with one branch of their profession, had startled the world by great blunders, such as Bramah stating that the steam-engine would never become workable, and the elder Brunel that a steamship would never cross the Atlantic. No one could tell what was lost to the world by ten years' adherence on the part of a country to the mistaken views of such men, and the existence of a school like this was one of the safeguards which the world had against the dangers arising from the blunders of eminent men.

MR. E. M. BARRY, R.A., has submitted a report upon the best means of improving the accommodation in the House of Commons for reporting the debates. He proposes to alter the shape of the northern gallery of the Chamber by substituting a horse-shoe formation, and taking in a portion of the members' galleries to the right and left so far as the doors leading to the writing-rooms over the division lobbies. It is also proposed to make four rows of seats in front of the curve, with desks attached. Space for two of these rows, it is suggested, should be obtained by cutting away the partition at the back of the present gallery, and impinging upon the ante-rooms under the ladies' gallery. Professor Barry's report has been submitted to the Select Committee appointed to consider the subject of Parliamentary reporting.

THE Indian Government has instructed Mr. Guilford Lindsay Molesworth, M. Inst. C.E., the Director of Indian State Railways, to submit designs for a bridge across the Indus. Mr. Molesworth proposes to cross the main stream by a single span of 750ft., and in its construction he contemplates the use of steel only. The Indian Government considered that before committing itself to final acceptance of Mr. Molesworth's designs it would be most desirable that that gentleman should proceed to England and make himself fully acquainted with all the results of the most recent practice with steel, and with such details as to its manufacture and testing as should enable him to be able to specify with confidence the method in which the work should be carried out. His design of such a span as 750ft. is un-

doubtedly bold, and is not exceeded by any girder structure yet erected in any part of the world. The enterprise is a novel one, and will open the road to the future development of the use of this material, which, although as yet in its infancy in such forms of application, promises to be the material of the future. Its employment, owing to its light scantling, will render novel and special forms of construction necessary to guard against the tendency to buckle likely to manifest itself in such a great span as that of the proposed girder.

THE Board of Conservancy of the Thames have sent a return to the Local Government Board which will soon be in the printer's hands, and which will show that we are still drinking the sewage of Oxford. At present the Conservancy Board are pressing the authorities of the City and University of Oxford to cease from pouring their sewage into the drinking water of London, and the members indulge a hope that the filth of Oxford may in a short time be diverted from the river Thames. It is not long since Reading and Windsor added their sewage to the drinking water of the West End of London, not to mention some forty or fifty small towns and villages. Even when Oxford has ceased from polluting the Thames we shall have to endure contributions from the streams which contain the washings of the highly manured lands of the river basin, to say nothing of the incidents of traffic upon the stream above the intake of the water companies.

CLEOPATRA'S Needle is again encased in scaffolding, the Metropolitan Board of Works having, after a few months' deliberation, given assent to a scheme for coating it with a solution devised by the Indestructible Paint Company, in order to protect the stone from a London atmosphere and climate. The scaffolding has been erected by Messrs. John Mowlem and Co., the general contractors to the Board, who are at present also paving the landing-stage in front of the obelisk with granite. Some of the blocks are of unusually large dimensions, several measuring 11ft. 6in. by 5ft. When the scaffolding has been completed the obelisk will be cleansed with soap and water from the soot and impurities it has accumulated since its erection in September last, and the indestructible paint will then be applied under the personal supervision of Mr. Browning, manager to the company.

THE members of St. Paul's Ecclesiastical Society made their first architectural visit on Saturday under the direction of Mr. George H. Birch, A.R.I.B.A., who so arranged the excursion as to be illustrative of a paper on "Norman Architecture," read before the Society on the previous Wednesday. The members met at the Church of St. Bartholomew the Great, Smithfield, and were received by the rector and by Messrs. J. P. Seddon, F. T. Dollman, F. C. Penrose, H. Rounnie Gough, and A. R. Hoole, architects. Mr. Birch gave a short historical sketch of the foundation of the priory, of which the present church is a fragment, consisting of the choir, the great central lower arcade, and one bay of the Early English nave, and proceeded to point out the salient features of the Norman style—the massive columns with their severe bases and capitals, the mouldings of the arches and triforium, the vaulting of the aisles, and the remains of the apse. Regret was expressed that the restoration of this church has been for the present brought to a standstill. The members next visited the St. John's Chapel in the White Tower, and afterwards the crypt and cloisters, Westminster Abbey, Mr. Birch giving, in each instance, an architectural and historical lecture.

THE members' soirée of the Architectural Association was held at the Society's rooms on Friday evening last, when a very considerable number of the members were present. No programme had been prepared for the evening's entertainments, which were of the most simple and ordinary kind, including songs and recitations. The walls were hung with a collection of drawings and paintings by Colonel Fairman, noticed by us last week, and in the second gallery some water-colour sketches by members of the Association were arranged, as well as the drawings intended for reproduction in the proposed memorial work to the late Mr. Edmund Sharpe. Mr. Phené Spiers urged upon the members the duty of subscribing to this work, by which they would secure, not only a valuable

book for themselves, but assist in executing a simple duty incumbent upon them all as a body, finishing a work Mr. Sharpe had himself begun, and so erecting a slight memorial to their worthy leader, who had done so much for the welfare of the Association. If so good a proposal needs any recommendation we most thoroughly endorse it, and hope that several who are not members of the Association will send in their names as subscribers.

THE Council of the Society of Arts, having received an application from the City and Guilds of London Institute for the Advancement of Technical Education, offering to take charge of the Technological Examinations established by this society in 1873, and carried on up to the present time, have resolved to transfer these examinations to the charge of the institute. The Council have also ascertained that the Science and Art Department will assist the City Institute in conducting the examinations, in the same way as it has hitherto assisted the Society of Arts. The Technological Examinations for the present year will, therefore, be carried on under the direction of the institute, and all communications on the subject should be addressed to the Hon. Secretaries, City and Guilds of London Institute, Mercers' Hall, E.C.

THERE is nothing of an encouraging nature to report respecting the timber trade during the past week, which, like its predecessors for some time, has been one of extreme quietude. The importations have only been moderate, yet quite sufficient for the demand, and even more so. There have been a few cargoes of Norway battens landed at the North-Eastern ports, which have been sold at low prices, some as low as £4 10s. per standard c.i.f. The shipments from Sweden have not yet commenced to arrive, except by steamer from Gothenburg. The cargoes that have arrived during the past week consisted principally of mining timber and pit props, on consignment, and have been sold at low prices—round timber at 20s., and square at 18s. per load; 3in. props at 2s., 4in. at 3s., and 5in. at 4s. 6d. per 7½ft. c.i.f. The sawmills are very slack of work, and are running short time. Freights continue very low, with no signs of improvement.

CHIPS.

Arrangements have been completed for the erection of a new theatre in Glasgow at the corner of Sauchiehall and Renfield-streets, by a limited liability company, at a cost of £20,000. The theatre will be Franco-Italian in style, and will accommodate 2,000 persons. It will be 109ft. long, 56ft. wide, and 43ft. high, and will be provided with a balcony and gallery.

On Thursday in last week the Corporation of Waterford received and accepted a provisional order from the Local Government Board for Ireland enabling the Corporation to borrow £15,000 to complete the new water-works, on which £50,000 have already been expended. It was determined to proceed in the matter as quickly as possible.

A window on the south-side of Blewbury Church has been filled with stained glass. The subject is the Good Shepherd, and the work has been carried out by Messrs. Heaton, Butler & Bayne, of Garriek-street, W.C.

During the progress of building excavations opposite the ancient Castle at St. Andrew's, a subterranean passage 4ft. wide was found cut in the solid rock at a depth of 16ft. or 18ft. below the surface. It has been traced to an exit under the ward immediately on the south-east side of the castle gable. Of course it may prove to be a sewer, but tradition avers that an underground communication existed from the castle to the cathedral, or the residence of Mary Queen of Scots, at the east end of South-street. The passage is being further explored.

At a meeting of the Wymondham Burial Board on Wednesday week it was decided to build two mortuary chapels in the cemetery.

The Parish Church of Llandewi-Skirrid, in the diocese of Llandaff, is about to be re-built, with the exception of the tower, and enlarged. The work is being carried out at the cost of Mr. Crawshaw Bailey, and is estimated to amount to about £1,500.

Works of sewerage are about to be carried out at Cirencester, from the plans of Mr. Grantham, C.E. The estimated cost is £13,375.

A new parish clock on the restored tower of the church of Stratford St. Mary, Suffolk, was set in motion on Tuesday week. It has been manufactured by Messrs. Smith & Son, of St. John's Square, Clerkenwell, at a cost of £127, has two dials, and strikes the hours on the tenor bell.

A new saloon and assembly-room is being built on the West Cliff Slopes at Whitby at the sole expense of Sir George Elliott, M.P. It will be opened early in the season. The pleasure-grounds, terraces, roads, walks, and approaches are in process of formation. The architects are Mr. Julius Mayhew, of London, and Mr. E. H. Snales, of Whitby. The builder is Mr. John White, of Whitby.

A three-light stained-glass window and a memorial tablet have been placed in the Parish Church of St. Andrew, Borcham, Essex, in memory of the late Sir J. Tyssen Tyrell, Bart.

The death is announced of Mr. William Wright, builder and architect, of Great Yarmouth. The deceased, who was in his 70th year, was for twelve years a member of the Town Council of Yarmouth.

A general committee has been formed, consisting of members of the Somerset Archeological Society and of the Town Council, to arrange for the reception of the Royal Archeological Institute, which will visit the town in August. The Bishop of Bath and Wells has been appointed president for the year.

A limited liability company has been formed at Folkestone, with a capital of 4,000 shares of £1 each, for the purpose of providing a working man's club and institute in that town, the proposed buildings including a club-house for the use of friendly societies, a large concert and lecture-hall, baths, and lavatories. The eleven directors are all resident in the neighbourhood, and include a builder, a carpenter, a mason, a joiner, and a bricklayer. The architect to the company is Mr. Reginald Pope, of Folkestone.

An arrangement has been come to by the Parliamentary Committee of the Lancashire Corporation and the Directors of the Gas Company in that town for the purchase by the Corporation of the gasworks for the sum of £80,000, plus £7,000 for the redemption of mortgage bonds. The agreement remains to be confirmed by the whole council and the ratepayers.

At a recent meeting of the Cumberland and Westmoreland Archeological Society it was decided to have an excursion in June next from Penrith to Barton Church and other places in that vicinity.

The Archbishop of York, on Tuesday, reopened the church of St. Mary's, Birdsall, which has just been thoroughly restored and enlarged, at a cost of over £3,000, comprising the complete renovation of the nave of the church and the addition of a new stone chancel. A new reredos, of Bath stone, richly decorated, has also been inserted.

We have been asked from time to time to give lists of celebrated organs and the names of their designers. A very complete table of over a hundred examples, giving date of erection, name of architect or builder, and the style of decoration adopted, appears in this week's *ENGLISH MECHANIC AND WORLD OF SCIENCE*, compiled by Mr. J. Watson Warman, A.C.O., and may be found useful for reference by many readers.

A very large block of residential chambers is to be erected forthwith at Knightsbridge, adjoining Hyde-park, from the designs of Mr. Bentley, architect, of the Adelphi. The style is a sort of Queen Anne, very simply treated in brick. We can but remark how readily the leading Gothic architects forsake their style, for that against which they have so loudly protested.

An admirable portrait of Mr. J. R. Clayton (Clayton and Bell), by Mr. J. E. Hodgson, A.R.A.,

and a striking likeness of the late Mr. F. P. Cockerell, the architect, by Mr. G. F. Watts, R.A., are well hung at the Royal Academy this year.

Of all the quaint and curious frames to the pictures at the Royal Academy this year, that of the series of pictures illustrating Ahab's Coveting, by Mr. T. M. Rooke, is the most singular and elaborate. It is in a sort of Egyptian style, and quite the work of a painter.

The President and Fellows of St. John's College, Oxford, have accepted an estimate for the restoration of the front of the college, including a new hall and kitchen, upon the designs submitted by Mr. Gilbert Scott. The amount proposed to be expended is £10,000, and a beginning will be made at the commencement of the long vacation.

We are asked to state that the Annual Conversation given by the President of the Institution of Civil Engineers will this year be held on Monday, the 26th of May, in that portion of the South Kensington Museum which contains the engineering and naval models and machinery. Mr. Bateman, the president, in making this announcement at the last meeting, invited the members to lend for the occasion any suitable novelties, so that the already varied and extensive collection may be supplemented by examples of the latest developments of mechanical and engineering science.

The Portuguese animal-painter, Thomaz José Annunciação, died suddenly on the 3rd inst. at Lisbon. He was the director of the Academy of Fine Arts at Lisbon.

The Goldsmiths' Company has distributed £50, and the Fishmongers' Company 50 guineas toward a fund for establishing scholarships in the London Female School of Art.

A new Wesleyan chapel at Whitechurch, which has been erected at a cost of £6,000 from the plans of Mr. Rogers, of Preses, by Mr. Stringer, of Sandbach, was opened last week.

New schools are about to be commenced for St. Boniface's German church, Whitechapel, from plans drawn by Mr. John Young, architect. The cost of the building will be £1,600.

The foundation stone of a new mission chapel was laid at Wheatcroft, near Scarborough, last week. It will cost a little over £800. Its interior dimensions will be 79 feet by 20 feet 4 inches, and it is to accommodate about 240 persons.

The Roman Catholic church of St. Wilfrid, at Preston, is being gradually rebuilt from the designs of the Rev. L. Scholes, S.J., the son of an architect. The new aisle, or Lady chapel, will be opened on Sunday next, the 4th inst. It is of three bays, is Italian in style, and is constructed of brick, with terra cotta dressings. The benches are of pitch pine, with mahogany book boards. There are a baptistery, and four confessionals. At the end of the aisle, a flight of stone steps leads to an upper room or chapel, which will also form a tribune, looking into the proposed new nave.

The tender of Messrs. Thompson, of Peterborough, has been accepted for the restoration of the nave and chapter-house of the cathedral of Bangor, from the designs of the late Sir Gilbert Scott, R.A. The works were commenced yesterday (Thursday).

At a meeting of the Carlisle Diocesan Church Extension Society, held on the 17th April, the following grants were made in aid of church building:

Dearham, £73 6s. 8d. towards new aisle and transept; Thursley, £15; Crosscanonby, £50; Seberg-ham, £50; and Mansergh, £92.

Mr. Thos. Robinson, of Wycombe, died on Saturday week, aged 85. He had been a surveyor for the Reading and Hatfield turnpike road for 44 years, to which office he was originally appointed under Sir James Macadam.

A new Baptist tabernacle was opened at Henley-on-Thames, last week. Mr. Clements, of that town, was both architect and builder.

St. James's Church, Gloucester, is about to be enlarged from designs by Messrs. Waller and Sons, of the city. The church, which was built about 10 years ago, at present forms a parallelogram, 79 feet by 33 feet, placed north and south, and has no definite chancel. By adding an eastern aisle, 71 feet by 12 feet, the accommodation will be increased from 624 to 900 sittings, after re-seating the whole church. An extension will also be made on the south, so as to provide a chancel with organ, chamber, and choir aisle.

The restoration of Ehnore church is about to be commenced, the tender of Messrs. Gyde and Co., of Pitchcombe, having been accepted at £1,550, for the execution of the work. The architects are Messrs. Waller and Sons, of Gloucester. It is intended to place new roofs over the whole building as the existing ones are dilapidated and dangerous. The church will be refloored and rescaled, the walls, windows, bell framing, and plastering repaired, and gutter courses will be placed all round the building.

On Tuesday week the new church of St. Matthew, Littleport, was consecrated. The buildings and fittings have cost about £1,600. It is built with red and white brick, with Bath stone dressings, and will seat about 240 persons. The architect was Mr. W. Smith, 10, St. John's-street, Adelphi, London, and Mr. E. Brown, of Lynn, was the builder.

An address of congratulation from artists resident in Scarborough to Sir Frederick Leighton (who is a native of the town), on his appointment as President of the Royal Academy, is now completed, and will be presented in the course of a few days.

A bill forbidding the erection of chancel or rood screens in any place of worship of the Irish Church was on Tuesday, in the general synod, Dublin, thrown out upon the second reading.

A new school, erected by the School Board of London, was opened at Tanner's-hill, Deptford, on Friday. It is of the usual Queen Anne character.

Negotiations are in progress for the purchase of land at Sunningdale, Berks, for H.S.H. Count Gleichen, upon which it is proposed to build a new residence from the designs of Mr. David Brandon, F.S.A.

The Lowestoft Improvement Commissioners have resolved to call in Mr. Peter Bruff, C.E., of Ipswich, to examine and report the best means of protecting the sewage outlet on the beach.

Mr. Boehm, A.R.A., has completed the model of the monument to be erected in the Mausoleum, at Windsor, in memory of the late Princess Alice. The monument itself will be completed in ten months.

At Nottingham police-court on Tuesday, a charge of obtaining £50 by means of false pretences brought against John Sontheran, joiner and builder of that town, which has been gone into on five or six occasions, was dismissed.

Roofing Felts.—F. Braby & Co.

INODOROUS, SARKING, SHEATHING, AND HAIR FELTS KEPT ALWAYS IN STOCK. MANUFACTURERS OF PERFORATED ZINC, PERFORATED COPPER, AND PERFORATED IRON IN VARIOUS DESIGNS AND GAUGES.

Wrought Iron Tanks.—F. Braby & Co.

PAINTED AND GALVANISED, OF IMPROVED MANUFACTURE

Corrugated Iron.—F. Braby & Co.

GALVANISED AND BLACK IN ALL GAUGES, KEPT IN STOCK. ZINC WORK OF ALL KINDS.

FITZROY WORKS, 356 TO 369, EUSTON ROAD, LONDON.
HATTON GARDEN, LIVERPOOL. GREAT CLYDE STREET, GLASGOW. AND AT CYPRUS.

The members of the Cheltenham Fine Art Society on Tuesday week presented Mr. Sidney Herbert, artist, of Carlton Lodge, Cheltenham, with a Sevres tea-service and a purse of gold, as an acknowledgment of his services to the society, and to the cause of art in Cheltenham.

A memorial baptistry is about to be erected at St. John the Baptist's Church, Bathwick, in the angle between the tower and the north-west portion of the church, the space between the baptistry and nave being arcaded and filled with light iron grilles. The plans have been prepared by Mr. A. W. Blomfield, M.A., under whose superintendence extensive additions were made to the church in 1870.

At Caerphilly, on Friday, the members of the Twyn Welsh Calvinistic Methodist chapel met to consider plans for the rebuilding of the chapel on the present site. According to a local daily journal, "a very pretty Gothic design was fixed upon, with a Gothic tower entrance," but the newspaper does not deem it necessary to acquaint its readers with the name of the fortunate author of this very pretty design.

A new Catholic convent is about to be built in Lillie-road, Fulham, from the designs of Messrs. Goldie and Child.

Various works of improvement are about to be carried out at the Church-in-the-Grove, Sydenham, under the superintendence of Mr. J. Toller.

A line of pneumatic tubes is being laid down Fleet-street and across Ludgate-circus, for a service of pneumatic dispatches between the General Post-office, St. Martin's-le-Grand, and the branch offices in Ludgate-circus and Chancery-lane. The work is being carried out under contract by Messrs. Reid Brothers, Mr. Dilks foreman.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Society of Engineers. Paper by Edward D. Barker on "Hydraulic Continuous, and Automatic Brakes," 7.30 p.m.
Society of Arts. "Recent Advances in Telegraphy," by W. H. Preece. Lecture, No. 3.

Royal Institute of British Architects. Annual general meeting for election of officers, &c., 8 p.m.

WEDNESDAY.—Society of Arts. Paper by Lloyd Wise on "The Government Patent Bill," 8 p.m.

THURSDAY.—Society of Arts. Lecture No. 1, by W. H. Perkin, on "The History of Alizarine and Allied Colouring Matters and their Production from Coal Tar," 8 p.m.

Society for the Fine Arts. Lecture by T. H. Wright on "The Music of the Harps, and National Airs of Ireland and Scotland," 8 p.m.

FRIDAY.—Architectural Association. Paper by J. Weale, "Notes on the Measurement of Old Buildings, having Special Reference to St. Alban's Abbey," 7.30 p.m.

Royal Institution. Sir John Lubbock on "The Habits of Ants," 9 p.m.

SATURDAY.—Royal Institution. H. H. Statham on "The Leading Styles of Architecture Historically and Aesthetically Considered," No. 3. 3 p.m.

HELLIWELL'S Patented NEW SYSTEM

IMPERISHABLE GLAZING WITHOUT PUTTY. All Woodwork is covered, and no outside painting is required. Old Roofs Re-glazed. Any one can repair or take in pieces.

See half-page Advt. in next Number.

T. W. HELLIWELL, Brighouse, Yorkshire;
or, 19, Parliament-street, London.—[ADVT.]

Holloway's Pills.—Colds, Catarrhs, and other febrile affections can be readily arrested in their early stages by these Pills. If taken according to their accompanying directions, in addition to their cooling and purifying properties, these Pills control the circulation, reduce febrile symptoms, relax the skin, promote perspiration and restore health.

Trade News.

WAGES MOVEMENT.

AYR.—As the result of a conference between masters and men, it has been agreed that the masons' wages be reduced ½d. per hour. The masters at first proposed 1d.

BARNSELY.—Yesterday the whole of the masons and labourers employed by various firms in Barnsley struck work against an extension of hours and a lower rate of wages. The masters gave three months' notice, which expired yesterday. They demand half an hour more work per day, and payment by the hour instead of the day. The men have offered to accept a reduction of 3s. weekly, and to work by the day, but they decline to work longer hours.

BLACKBURN.—The employés in the building trades in Blackburn, including bricksetters, masons, slaters, plumbers, and joiners, have had notice given them that their wages will be reduced 1d. per hour. No change is to be made in the number of hours.

CARDIFF.—At a meeting of carpenters and joiners held on Saturday, to consider the proposals made by the master builders at the recent conference, a resolution was passed expressing the men's opinion that the exigencies of the building trade in Cardiff are not so pressing as to call on them to accept a reduction. This was ordered to be forwarded to the Master Builders' Association.—The plasterers of Cardiff have voluntarily offered to accept a reduction of ½d. an hour in their wages, which they consider called for by the state of trade.

LEEDS.—The impending strikes in the Leeds building trade have been averted, the masons and labourers accepting a reduction of a halfpenny per hour.—The cabinet makers of Leeds had been on strike a week against a proposed reduction of 5 per cent. on the union scale of wages. On Monday they resumed work, conceding the demand of the masters.

LIVERPOOL.—A general reduction in wages and longer hours by the Liverpool building trade operatives, excepting the plasterers, has been accepted. They, however, object to start work at six o'clock in the morning. Forty-eight hours have been given them to reconsider their decision: failing that, a strike will ensue.—On Thursday night, at an aggregate meeting of the joiners of Liverpool, it was agreed to accept a reduction of ½d. per hour. The masters' original proposal was a reduction of 1d. per hour, which was met by an offer from the men to accept ½d., and the dispute has been settled by the compromise indicated above.

NORTHAMPTON.—Four hundred men engaged in the building trade at Northampton struck work on Saturday against a reduction of a halfpenny per hour in wages.

Douling Freestone and Ham Hill Stone of best quality. Prices, delivered at any part of the United Kingdom, given on application to

CHARLES TRASK,

Norton-sub-Hamdon, Ilminster, Somerset.

Agent: Mr. E. CRICKMAY, 4, Agar-street, London, W.C.—[ADVT.]

TENDERS.

BENGOE.—For laying additional water mains at Bengoe, for the Hertford Rural Sanitary Authority. Messrs. Smith and Austin, Hertford, hydraulic engineers. Quantities supplied:—

Hudson, C.	£115 0 0
Raymont, J., and Son	105 0 0
Gairr, R. (accepted)	93 6 0

BERKHAMPTSTEAD.—For the erection of play shed, upper and fives' courts, boundary walls, corrugated iron fence, and terrace paving, for the governors of the Berkhamstead Grammar School. Mr. C. P. Painter, engineer and surveyor:—

Osborn	£1,016 5 0	without ground work.
Monk	921 17 6	" "
Fincher and Smith	918 0 0	" "
Cook (accepted)	922 0 0	including ground work.

BOSTON.—For the execution of engineer's work in connection with the baths about to be built by the Corporation:—

Tuxford and Sons, Boston (accepted)	£405 13 6
--	-----------

[Twenty-five tenders received, the highest being £1,850 and the lowest £355.]

BOSTON.—For the erection of the new baths about to be built for the Corporation:—

Lucas, John (accepted)	£2,557 10 0
-------------------------------	-------------

BRENTWOOD.—For the supply of iron pipes, for the Shenfield and South Weald Special Drainage District, Essex:—

Henderson, Gracechurch-street, E.C. (accepted)	£490 0 0
---	----------

CIRENCESTER.—For gasfittings in new board schools. Mr. Tripp, architect to the Cirencester School Board:—

Lane, W.	£73 10 0
Tovey, J. and H.	55 0 6
Alexander and Thompson	44 15 0
Gillman and Son (accepted)	37 2 6

[Architect's estimate £45.]

CROYDON.—For commercial school and residence, Oakfield-road, for Mr. Thos. Lerrey. Mr. T. Brookes, architect. Quantities by Messrs. R. L. Curtis and Son:—

Mutch, W.	£2,350 0 0
Jarrett, C.	2,200 0 0
Saker, J.	2,200 0 0
Coles, C.	2,267 0 0
Legg, H.	2,249 0 0
Taylor, M.	2,195 0 0

DEPTFORD.—For the erection of lodges, stables, and disinfecting and destroying apparatus on the premises of the Greenwich District Board of Works, at Knott-street, Deptford:—

Mace (accepted)	£2,640 13 0
------------------------	-------------

HODDERSDON.—For laying additional sewers at Hodderson, for the Ware Rural Sanitary Authority. Messrs. Smith and Austin, Hertford, sanitary engineers. Quantities supplied:—

Nicholls, J. W.	£160 13 0
Taint, J. A.	160 0 0
Gray, W.	152 0 0
Strachan and Co.	150 0 0
Rowley, T.	140 0 0

THE BUILDING NEWS.

LONDON, FRIDAY, MAY 9, 1879.

THE PICTURES AT THE ROYAL ACADEMY.

THE 111th Exhibition of the Royal Academy will bear a favourable comparison with most of those which have preceded it, though we miss some old friends, and have to regret the falling off of a few artists who once were thought to be deserving of high honours. The President shows no less than eight pictures, the most important, No. 188, being the fine representation of "Elijah in the Wilderness," which was deservedly so much admired in the Paris Exhibition. The prophet has sunk to sleep overborne by his anxiety and toil. As he tosses about restlessly on the hard rock, the angel who has brought him food watches over him with kind compassion. The drawing of the principal figure is admirable. No. 119, "Biondina," a study of a fair, blue-eyed girl dressed in a blue bodice over white linen, trimmed with red bows. There are other similar portraits of equal merit, the most important, and in some respects most pleasing, of which is "Amarilla," No. 289. The lovely girl stands facing the spectator under a trellis covered with vine, the dark blue of the distant Mediterranean at the back harmonising with the quiet stillness suggested by the scene. Mr. Millais has surpassed himself; a finer portrait than that of Mr. Gladstone (No. 214) has seldom adorned the walls of the Academy. In strength and portrayal of character it reminds one of the best works of Moroni—but its manner of treatment and handling is all original. No one, as far as we know, has ever produced such perfect effect with so little apparent labour. You seem to see the man himself—every line, every hair, every characteristic of mind and feature.* No. 274, a portrait of a lady, is also a masterly production, but hardly so successful, except in the magic representation of the various textures of the dress, as the above. The flesh seems powdery and untruly coloured—a defect which time will probably increase. In No. 150 we have a new and bold exhibition of the artist's varied powers, "The tower of strength which stood, Four-square to all the winds that blew." A rough old square-built tower, now a ruin, stands on a jutland, surrounded on three sides by a rough, chopping sea. The sky, stormy and lurid, suggests the sort of tempests the sturdy old building has had to bear for a thousand years or so. We see little to admire in the works of C. W. Cope. No. 232 is a weak and stagey scene from "Hamlet," where poor Ophelia offers to return his costly presents which he pretended not to have given her. The colour is all unnatural, the drawing tame and devoid of character or feeling; nothing looks real about it. The very architecture is as unlike anything that was ever done, as Alma Tadema's is always true to the most minute detail. The picture of Solomon Hart, and those of Charles Landseer, though, by right of the painters being Academicians, occupying valuable space upon the line, do not call for criticism. It is a pity, when many deserving works are of necessity rejected on account of the large number of paintings now sent in, that something cannot be done at least to prevent such things being placed in important positions. Mr. Orchardson again gives us a dramatic incident of eighteenth-century life. No. 287, his only picture, is named "Hard Hit." The subject is commonplace enough, but under the masterly hand of the artist escapes tameness.

* This portrait is, we are glad to learn, to be engraved by Mr. T. Oldham Barlow, R.A.

In a handsomely-furnished room, as will happen where play is high in all countries, three clever rogues, though in garb of the best society, have got the better of a younger dupe, who is leaving the room after having dropped his money. How hard and long they have been at the game is shown by the heaps of cards which bestrew the floor of the apartment. We are reminded of Greville's account of what took place at Outlands. Everything is strictly in keeping. The smooth polish of the host rising to bid his unlucky guest, "Good morning," as he stands about to open the door; he being too much occupied with his ill-luck to return the civility or notice the chair which he overthrew as he rose from the table; the sinister, inquiring look of the host's opposite partner, and the cunning pretence of concern in the old stager who is shuffling the cards, are excellently described. The handling altogether is very slight, almost to a fault.

T. Faed also exhibits but one painting, No. 207. It is in his best manner, and the subject is joyous and happy. Free from care, a handsome young peasant woman is seated beside her baby, who is lying asleep under an improvised canopy to keep off the hot sun. All among the flowers, some of which she is making up, together with some bright red berries, to delight her little one when he awakes. All is sunshine and brightness. J. R. Herbert again gives a scene in Palestine. Young St. John Baptist is seated in a desert place, apart from the haunts of man, studying from a parchment scroll. His mode of living is shown by a partly-eaten honeycomb and two or three locusts at his side. A good deal of pains has been taken in painting the hot barren waste, but the effect of the whole is not successful. Altogether better, as a religious picture, is Mr. E. Armitage's fine and scholarly painting of the "Woman taken in Adultery." The story is singularly well told. The woman stands in agony of shame and terror, while the chief accuser is vehemently urging the enormity of her offence, unheeding the words which the Saviour is tracing upon the dust at His feet. Not so the other zealots at the right hand of the picture: they begin to see what is being written, and can scarcely believe their eyes. The contrast of character seems symbolised in the great and strong contrast of colour.

In No. 261, Chester Loomis sends a good, though somewhat tamely-treated attempt to revivify incidents of Mediæval times. It is called "Justice in 1500." A deer-stealer has been caught with red hands, just as he had shot a young stag. He is brought into the council-chamber of a young lord, of about the age of six years, whose mother sits at his left hand, not apparently taking much notice; the real actor in the scene being an ecclesiastic, who stands at the young magnate's right hand. The whole is a well-studied ideal of what might have happened at the period, but is not of a very high order. Nothing could be more beautiful than Vicat-Cole's grand summer landscape in the great room (No. 245), "Ripening Sunbeams." The landscape indeed stretches wondrously fair, no paling beauty anywhere—Nature is in her prime. The time chosen is just the beginning of harvest; a glorious scene of rich valley, well wooded, with oaks in richest foliage, stretching away as far as the eye can reach. In the foreground the rich golden corn, moved in many-shadowed waves, breathed on by the quiet wind; the only interruption to the stillness that prevails being the songs of the birds and the distant creaking of the heavily-laden waggon. It is a perfect and lovely picture of the fairest scene that England's richest prospect can offer to the enchanted sense. Bright and fresh is the sea that washes the shingle beach of the Fishermen's Village, No. 269. "Little to earn and many to keep" is evidently true enough of the rough old salt, who

has just returned from the herring fishery; and yet, rough and hard as his life is, he and his are not without their joys. As the hearty fellow kisses his healthy baby, his boy of ten or twelve walks off in triumph with his father's big boots under one arm, and a lot of herrings for dinner under the other. Both this and No. 275, "The Mushroom Gatherers," are capital productions of J. C. Hook's brush. An intimate study of nature, and especially of the ways and natures of the dwellers on our coast, is shown in these most natural and interesting scenes. The humour and felicity of choice of subject which is always observable in H. S. Marks' works is conspicuous this year. All three of his pictures are excellent. No. 73, "Intellect and Instinct," shows how the instinct of a dog may be sometimes more useful than the cleverness of man. An old gentleman is so engrossed in what he is reading as he walks, that he drops some of his papers in his forgetfulness. Doggy comes to the rescue, and stays by them doubtless till his master finds out his loss. No. 379, "Science is Measurement," is the diploma picture deposited as is the rule, on his election as an Academician. An ornithologist, with tape in hand, is measuring the skeleton of an adjutant-bird. There is a good deal of character about the enthusiastic savant. The drawing is perfect. The best of the three is "Old Friends" (No. 251). Two old Greenwich pensioners are wandering together over the yard of a ship-breaker, when they recognise their old friends, the figure-heads, which they once knew adorning the bows of some of the men-of-war of their younger days. It is evidently with great admiration that they look up to their old associates. T. S. Cooper's seven cattle-pieces are all of the same description that we have been used to for several years, perhaps a trifle more effeminate. The cattle are, if anything, cleaner and smoother than ever, and all of the same kind. Edwin Long this year, instead of one great subject, sends several. Though they are less conspicuous than such pictures as "The Gods and their Makers," of last exhibition, they are none the less admirable. "Esther" (No. 102) preparing to go into the king to plead for her people, sits full of her high purpose, yet anxious and fearful, while her handmaids array her in lovely Eastern costume, themselves doubtful and sorrowing for the danger of their beloved mistress—for who could fail to love her? What strikes one in this picture is the perfect unity in all the parts. The companion, "Vashti" (No. 955), is nearly as good. She is represented as a beautiful blonde, angry and grieved—weeping at the unreasonable anger of the infatuated king. We reserve for future notice the two other works of this accomplished painter.

ARCHITECTURE AT THE ROYAL ACADEMY.

[SECOND NOTICE.]

ARCHITECTURE, as one of the arts supposed to be taken under the fostering care of the Royal Academy, is more meagrely represented this year than last. Only two of the walls of the one gallery devoted to works of this class are occupied; the screen has been given up to etchings and engravings, so that actually British architects are confined to the smallest half of the gallery at Burlington House. This may appear a slight matter; but it fortunately happens that the Academy show does not fairly represent the architectural ability of the country, for somehow works are exhibited there that ought not to find a place upon the walls at all, while of the principal works of the year there is a very indifferent exhibition. As we last week took a general survey of the drawings, we shall in the present

notice take up those works only which are of representative interest. Rampant "Queen Anne" is certainly more moderately displayed this year, for, with the exception of Mr. J. J. Stevenson's "Ken Hill, Norfolk," (1,069), itself very moderate, and a few other very temperate drawings of residences, in a style that can only be regarded by a stretch of the imagination as coming under that designation, we see no attempt at sensationalism in style. So far this is a healthy sign. Mr. Stevenson's water-colour drawing shows a massively treated country residence, with none of that frittered effect we have before complained of. The yellowish tint of the stone walling does not certainly produce the happiest contrast of colour with the red tiled roof; the windows have pilasters and arched mouldings or pediments, inclosing the vousoirs, but the recessed bay window is open to question. Is this feature of inclosing a canted bay in an arched recess a hobby of certain followers of the style, or is it supposed to be an artistic feature? Till we have a satisfactory reply we must consider it a crotchet. One of the most noticeable examples of domestic architecture is Mr. Arthur W. Blomfield's "Denton Hall, Grantham." It is conceived in a quiet English spirit of Late Gothic, without any frivolous or capricious leaning to other styles, or straining for mere quaintness' sake. We should have liked to have seen a little more appearance of connection in the offices; but this effect is largely due to the want of breadth of shade in the drawing, a capital pen-and-ink one in other respects. Mr. Geo. Corson sends two bold ink perspectives, one of his School Board Offices at Leeds, and the other of the Municipal Buildings and Free Library in that town. In the latter we detect a very complete revision of the first competitive design—certainly an improvement, as we always thought the first rather monotonous in the sky-line. The drawings are anything but artistically rendered, and appear almost rigid in their severity of treatment. A few figures in the foreground, and a little more shading in the last-named, would have relieved the uncompromising austerity in the lines of the architecture, which at present have an unfinished air. Mr. Corson has adopted a free, though stern, phase of Palladian composition, which will associate well with the Town Hall. Mr. John Honeyman, in "Skipness, Argyllshire," has given a pleasing but chastely simple design; and Messrs. E. George and Peto have, in 1,086 and 1,087, contributed exceedingly piquant sepia sketches in a style they are not only admirably conversant with, but know how to render in a thoroughly artistic spirit. The "House at Pinner" (1,086) is equal to anything we have seen from Mr. Shaw himself; but the sepia drawing, of course, adds to the picturesqueness inherent in the style, and is a species of drawing we should be glad to see more largely employed for architectural purposes.

After looking at Messrs. George and Peto's sketches, "Knowle House, Wilts" (1,084), by Mr. R. H. Carpenter and B. Ingelow, has an exceedingly mechanical appearance about it due to the drawing which is not in the happiest tone of colour. As an architectural design of an Elizabethan type it has merits; the bay windows are well managed, and there is a breadth of treatment that reminds one of the Baronial style of the North, though the chimney caps are heavy. We hardly like "Two Houses at Stoneysgate, Leicester" (1,091), by Mr. Isaac Barradale, albeit the drawing is excellent. Canted windows have an awkward effect when carried up as gables; the bracketed treatment also is somewhat unsatisfactory, and gives a restless, fidgetty effect to the composition. The designs for the Church of the Oratory, Brompton, are numerous—perhaps overdone in the present exhibition. We are

certainly charmed with Mr. Geo. Nattress's fine water-colour drawing showing the west front of his design. While we do not approve of the design, or of the particular Venetian Renaissance model he has chosen for a London site, we admire the composition, and especially the tower. Mr. G. Gilbert Scott's design for the same church, showing the interior (1,100), is also cleverly and transparently coloured, though we take exception to the wide arches and the carved panelling in soffits and pilasters as rather redundant. No. 1,199, the selected design for this work, by Mr. Herbert Gribble, occupies the central position on the wall, and we need not say more than we have already said critically of the architecture, which we illustrated both internally and externally in our last number. As an architectural drawing in colour, Mr. Gribble's interior, if rather weak and washy, can fairly compete with any in the room. The drawing of the arcade is exceptionally good, though we note the arch to the right is a little depressed; the colouring to the domical vault is quiet and harmonious, and the artist has produced a softened aerial effect almost to the fault of indecision, that gives scale, while it avoids that oppressive sense of colour and detail a cruder or more liny drawing would have given. One of the most pleasing water-colour sketches in the room is 1,094, Mr. A. Waterhouse's "Interior of New Court, Carey-street, Lincoln's-inn." Mr. Waterhouse has selected for his view certainly the most favourable point; the group of trees introduced, and the reflected light on the shaded side of quadrangle are very cleverly handled, and the drawing is in the happiest style of the author. The same architect's view of new offices of the Prudential Assurance Company, in Holborn, which we have illustrated in detail, hardly does justice to the design, and the return is rather more sharply drawn than is pleasing. A cleverly drawn water-colour view of the Giant's Stairs, Ducal Palace, Venice, by Mr. John Burney, is a delightful study of architecture and colour, though placed too high. Mr. Waterhouse also sends some new buildings at Pembroke College, Cambridge (1,102), certainly among the best examples of his work; but the arched stone parapet and the turrets scarcely make a pleasing combination with the Late Gothic and the red brick—but the building in the rear is more characteristic. No. 1,112, "View of Tower of St. Paul's, Manchester," by Mr. J. Oldrid Scott, is a finely proportioned work, with a gabled summit, from the intersection of the roofs of which springs a spire or flèche. The detail of the belfry stage is quiet and refined. The "Takhtsingji Hospital, Bhavnagar, India," in a Saracenic style, is a cleverly coloured drawing, in which the tropical tints of stone and sky have been ably depicted by the artist. Mr. Emerson has become thoroughly imbued with the Indo-Saracenic peculiarities, as this work testifies. Messrs. Goldie and Childs' interior for the Church of the Oratory, Brompton (1,110) competes favourably with those already noticed; the gilding is perhaps rather overdone, and whether the vaulted ceiling is circular or elliptical is not very apparent from the drawing, as the panelled soffits of the transverse arches are drawn as elliptical in the nearest bay, and circular in the distant bays. Mr. Basil Champneys in the "Divinity and Literary Schools, for the University of Cambridge" has shown a very rich example of Late Gothic, handled with considerable moderation, taste, and refinement; it is perhaps the best work of the kind in the gallery, as our readers may see for themselves this week. We pass a clever sketch for "Pulpit, Canford Church" (1,119), by Mr. W. C. Brangwyn, in which the author has endeavoured, if he has not fully succeeded, in treating that most difficult of all objects, a church pulpit. Mr. T. H. Wyatt's "Hospi-

tal for Consumption, Brompton," is certainly in a rather heavy style of red brick and stone; the brick preponderates, and the chief recommendation of the building—if it is one—is that it is hospital-like. We certainly prefer ourselves Mr. T. Roger Smith's design for consumptive patients at Hampstead, at the other end of room (1,173), conceived in a French chateau style of Louis XIV., and having more the character of a home for the sick, the recessed window treatment and balconies being especially a contrast to those of the former work. Mr. Smith's building is at least cheerful-looking, and will crown Vernon Mount with dignity. A painstaking drawing, executed by Mr. Maurice B. Adams, evincing much labour, shows Mr. Gilbert R. Redgrave's "English Half-timbered house at the Paris Exhibition" (1,103). It has been illustrated by us, and we need only remark that its great fault is over-elaboration in the timber ornamentation, and it scarcely can be taken as an example of English-framed houses, in which we have always remarked great breadth and simplicity. To show what diverse pattern can be introduced Mr. Redgrave's design serves admirably. The design exhibited for the Hampstead Hospital by Messrs. Tasker, Batherbury, and Huxley (1,125) is far too cut up, and the drawing has a rather crowded effect. Below we notice 1,126, "Interior of Chapel of St. David's College, Lampeter," by Mr. T. G. Jackson, cleverly drawn as a study of harmony in colour in the new blue-green shade. The roof, screen, and stalls are pleasingly harmonised in the general effect. Mr. Robert W. Edis exhibits a large and conspicuous line drawing of a house in New Bond-street, which we shall illustrate next week (1,132), displaying some skill in the treatment of a narrow frontage. Mr. Edis adopts a free kind of Renaissance, in which English and French detail is pleasingly combined. The fenestration is connected, and the only fault we find is with the elliptical-headed window below the corbelled circular oriel, the treatment of which is not in keeping. Mr. G. E. Street is represented by six choice exhibits in his usual style. We may notice St. Mary's Church, Speenhamland, Berks (1,133), as the least successful, and "Birds'-eye View of St. Margaret's, East Grinstead" (1,143), his best. The tower is treated as only Mr. Street or Mr. Pearson could treat it; it has a gabled or saddle-back finish, pierced by a series of lancets, very simple but dignified. The guests' house, cloister, kitchen-court, are appropriately treated, and the drawing is light and transparent. St. Peter's Church, Bournemouth, showing the spire (1,158), is perhaps one of the most successful of Mr. Street's smaller brick churches. The tower is dignified and remarkably quiet, pierced as it is with two lofty lancets in the upper story; the new spire is small, and is supported at its springing by pinnacles with small flying buttresses, while round the lower part of it is a series of gabled lights. Already the tower forms a highly picturesque object at Bournemouth, and we hope to illustrate it shortly. The same architect's "Designs for Houses in Cadogan-square" (1,174), is thoroughly Venetian in sentiment, and of less merit, though, as one of the domestic works of Mr. Street, it is interesting. A peculiar feature of the design is the angle balcony over porch, rather more fanciful than welcome. As a diversion amid the "Queen Anne" craze in that locality, it will be welcome. The drawing is rather spotty in effect. Messrs. Goldie and Child contribute (1,134) Interior of their Dominican Church, Waterford, a Romanesque interior, transparent in tone; and Messrs. George and Peto, some delightful cottages at Pinner (1,140); and a clever study for a drawing-room ceiling by Mr. G. G. Fox, harmonious in the choice of colour, though a trifle heavy in the cof-

fering. Unpretending as a cruciform treatment in an Early style is Mr. Blomfield's "Church of St. John the Evangelist, Wentbridge, Yorkshire" (1,136); Mr. W. West Neve's "Warehouses in Devonshire-street, City," though hung rather high, shows a sensible treatment of shop-fronts for narrow and dark streets. Occupying the place of honour in the top line is a large, exceedingly heavy coloured drawing, entitled "Decorations and Furniture," by Mr. W. Hensman, in a sort of Renaissance. The colouring is harmonious, but the architectural treatment of ceiling is ponderous, partly, perhaps, due to the depth of tone of the drawing. Mr. John D. Sedding sends a prettily timbered grange (1,159) in a clever and feeling drawing, which we intend to illustrate. It is marked by breadth, balance, and a delicacy of detail characteristic of this gentleman's work. Mr. T. G. Jackson's "New Quadrangle for Merton College, Oxford" (1,164), is a sepia bird's-eye view executed with much care, almost in the style of architectural colouring of half-a-century ago. The buildings shown are Renaissance, English in feeling. "Carlyle House, Chelsea Embankment" (1,163), by Mr. Adolphus Croft,—illustrated this week—is rather too broken up to be deemed a pleasing example of the style it reproduces; and we turn to Mr. Phené Spiers's mansion in the same locality (1,153) with relief, albeit it is a trifle fiery in colour. A sensible kind of brick Renaissance is chosen, this material being introduced largely in strings, pilasters, arches, window joints, and porch. The whole is crowned by a red-tile roof. We must notice in this review Mr. W. Scott's "Design for a Provincial Town Hall," which has been illustrated in our pages. This work has been singularly selected to occupy a place of honour on the walls, and in saying this we do not wish to disparage in the slightest the able drawing and conscientious labour of its author. There is ample evidence of skill in design in the drawing, but as a composition, we cannot say much in praise of it, and we hope Mr. Scott will be content next time to give us something less profuse, more moderate in his choice of architectural dialects, less hybrid and broken. One of the choicest, as it is one of the most delicate and artistic, drawings is Mr. Norman Shaw's "View of Adcote, Shropshire," which has been already illustrated in our pages. This is a diploma work, deposited by Mr. Shaw on his election as Academician, and admirably sustains that gentleman's reputation as a master of domestic English architecture of the later and more picturesque phases. It is impossible to say too much for the transparency, crispness, and detail of this line drawing and the finish and feeling it exhibits. Mr. W. Emerson's proposed tower for St. Mary's Church, Brighton, is a very fine composition; a low, circular slated spire springs from the square tower, and its grouping with the angle turrets produces a rich effect without loss of outline. We can only notice further in these remarks Mr. G. Gilbert Scott's façade for St. James' Church, Marylebone (1,178), as a remarkable but able design in a Venetian style. In concluding the present notice, we must remark a notable absence this year of any great works of composition or invention. There are few really striking architectural exhibits in any branch, and generally the exhibition is richer in drawings of a decidedly descriptive, if moderate character.

THE RAMSGATE NEW ROAD COMPETITION.

THOSE who have visited Ramsgate are probably aware that the frontage to the sea of that favourite watering-place has

a somewhat broken line of cliffs, that is to say, the steep escarpment is interrupted by a hollow in the centre, so that the cliffs on the east and west of the town are disconnected from each other, and the centre of the town in consequence forms a sort of chasm, destroying any means of easy communication. The Ramsgate Improvement Commissioners have lately determined, under a recent Act, to form a connecting link between these cliffs on the east and west, and accordingly invited engineers and architects to send in plans for that purpose, the result of which invitation is that no fewer than sixty-five sets of designs have been received, which are now on view on the West Cliff. As we intimated last week, Mr. Jas. Abernethy, C.E., has reported upon the plans and has awarded the first premium of £200 to the plan with motto "The Desideratum," by Mr. A. Cumings, of Tunbridge; the second premium of £100 to "Nee Timeo nec Spero," by Mr. Geo. Higgin, of Great George-street, Westminster; and the third of £50 to "Progrès," by Mr. J. Cardell Tounson, of Penzance. These plans selected by Mr. Abernethy will not, we understand, necessarily determine the scheme to be carried out, as the Board will exercise their own discretion in the matter, and the whole of the plans will be considered before a final decision is arrived at. It is at least satisfactory to hear that the Commissioners have not committed themselves to either of the three designs in its entirety, but that the schemes of the other competitors will be taken into consideration and a meeting of the ratepayers called to assist in the solution of so important a question for the town.

Let us first take the three plans upon which Mr. Abernethy has reported favourably. It is very obvious that there are two modes of dealing with the roadway: the first is that of making it connect the cliffs by slightly easing the gradients and allowing it to cross the existing streets on the level, taking a line more or less set back from the sea front, and a second plan is that of a high level roadway or viaduct connecting the cliffs at an easy inclination on each side, the viaduct crossing over existing streets in the hollow part of the town, and following a line of route on the front. We accordingly find the plans divide themselves broadly into these two classes, though there are several that show a treatment more or less of a compromise. "Desideratum" has adopted the first course, or the route suggested in the Parliamentary plan. It has the merit of at least connecting in an easy manner the West with the East Cliff without cutting too far inland, or necessitating a costly scheme of alteration of the existing streets. Starting from the West Cliff, the road follows the course of Military-road for some distance, which level it leaves unaltered; it then passes over a viaduct 227 yards long, to carry a widening of existing road over cliff, and passes over York-street on another viaduct of simpler kind. Crossing Harbour street on the level, it gradually rises, embanked by retaining walls, to Wellington-crescent, where it is carried with open parapets on the present levels. The gradients are 1 in 22 from Princes-street to Harbour-street; then a rise of 1 in 20 from the latter to Albion-place, after which, to Wellington-crescent, the present road level is slightly lowered. The widening of roadway over cliff on the western side is proposed to be accomplished by building arches into the solid cliff, the front of which is to be faced with concrete in blocks; the viaduct to have red brick spandrels, with pilasters and plinth of Portland stone. Access to the railway from the town is facilitated by a branch road from Albion-place, and it is proposed to widen the steps to the sands. The line is a good one, but we think the approaches in the centre of the town might be improved by a circus at Harbour-street crossing. The

estimated cost is £40,982. "Nee Timeo nec Spero" shows a high-level scheme, somewhat similar in route. The 50ft. roadway is carried by a widening-out of the cliff on the west by retaining walls; from Princes-street a viaduct of 226 yards is carried over the town, Princess, Leopold, Farley, York, and Harbour-streets, the road then passing in a diagonal direction through Albion-place-gardens; thence skirting the East Cliff promenade. The gradients are very easy, 925ft. being horizontal. We do not like the retaining wall mode of dealing with the West Cliff, which will present an unsightly front to the sea; and another disadvantage of the plan is that it presents no compensation for property taken, and advantage is not taken of the ready means of gaining store-room in the cliff. The estimated cost is £28,938. "Progrès" is a low-level road, the gradients being reduced on both sides, and the line of route chosen is a pleasing curve of double flexure; and this line, we may observe, is the natural frontage line of the town. The gradients are one in 150 to Rosehill, one in 224 to Harbour-street, then rising by one in 20 to Wellington-crescent on the east side. A viaduct crosses Princess, Leopold and Farley-streets, with steps; York-street is crossed by a girder bridge, Harbour-street level remaining unaltered. The arches are proposed to be of brick and concrete, and the roadway on West Cliff is widened by a series of arches built into the chalk rock with a retaining wall at the back, which presents the appearance of a viaduct to the front. This method has been adopted by several competitors, and is the least unsightly mode of widening the roadway over Military-road, and facing an escarpment in some places over 50ft. high. The design is well-shown by neatly-drawn elevations, and the plan certainly has the merit of being one of the best digested schemes for inclined approaches; cost is estimated at £20,481. "Che Sara Sara," follows the Military-road as far as York-street, then passes behind the Royal Hotel. The design shows an arched facing along the western cliff, the arches being utilised for stores; the gradient is rather steep, namely, 1 in 17½, as the road descends to Harbour-street. The author says by the adoption of this route the "principal hotels are untouched, their approaches improved, and few buildings interfered with"; but such a plea, we think, can hardly be urged unless the buildings preserved were really worth retention, or archaeologically interesting, which is not the case in the present instance. The lowest part of the new roadway is at York-street, and advantage is taken of this to form a cartway 20ft. wide as an approach to Military-road and basin. The estimate given for this plan is £28,387, and there is a carefully-tinted sepia elevation showing the viaduct. Another design under the same motto, distinguished by a square with 1'1—shows a route further back, cutting the centre streets, with retaining walls along the west cliff, following the present levels pretty closely. "Audacter et sincere" is the motto of an undoubtedly able plan, showing a front route and a high level roadway, and we hope that this and another design to be mentioned hereafter will be carefully examined. The plan shows a pleasing curve of roadway, following the cliff and basin of harbour with quadrant approaches on the east and west into Harbour-street as the central street of the town, so that the traffic from the middle portion may take an eastward or a westward direction to the new promenade, besides an improved approach to the station and sands. This diversion has been strangely overlooked by many of the competitors. The author of this design observes justly that though this route necessitates the removal of valuable property as compared with that further inland, he can obtain improved building sites, while the spaces under the

arches of viaduct can be let as shops and stores, so that the removal of the front properties, certainly not valuable at present, will more than compensate for the increased outlay at first. By this plan the cliffs are connected by easy promenades crossing over existing streets, and following the frontage line of the harbour, with uninterrupted views of the sea. A cleverly tinted sketch in sepia accompanies this design, showing the improved frontages and blocks of buildings that might be built at the junction of viaduct with Harbour-street, and the viaduct itself is made to form a sort of stylobate or platform for the new houses. The author has kept in view the fourth clause of the instructions issued, which provides, first, that the road shall, so far as possible, be kept to the front; secondly, provide access to the centre of town and to the sands; and, thirdly, interfere as little as possible with Military-road and the inner harbour. Another very able plan is that of "Westminster," it is rumoured by Mr. Ellice Clark and Mr. Pugin. This design is illustrated by a large coloured view of the town of panoramic comprehension. A high level promenade along the sea front, with roads in connection with it, forming easy access to the centre of town and with an approach to the sands, east pier, and London and Chatham Railway station, are its leading features. The gradients are easy, and the curved western branch road from the main route brings the business part of Ramsgate into immediate connection with the west cliff and harbour. Harbour-street is crossed by a bridge 20ft. above the present level, and new frontages are obtained both to the promenade and to that street, the latter having shops. Princes-street is widened and York-street crossed by an arch. On the east side two roads diverge from Club-alley, one leading to Harbour-street and the other to the sands and railway station; the custom-house is proposed to be removed, and Harbour-street to be widened. No. 2, an alternative scheme, follows the line of the Parliamentary deposited plan, but is obviously inferior in point of convenience and in the lines of promenade. The estimated cost of this design is £29,000. In the design under the motto "Front" the author, Mr. W. G. Osborne, architect, of Ramsgate, follows the line of front to the sea and steers to the west of the Albion Hotel. The plan shows a viaduct of ornamental design, girder bridges crossing Harbour-street and York-street, and a viaduct from York street to the end of York-terrace. The gradients are easy, and the steepest is 1 in 25. One very good feature in this design is that the frontages are well dealt with, shops and stores being proposed under York-terrace from the Street to Farley-place, the basements of the new houses being above the shops. The author sets back the houses 10ft. from the viaduct so as to give light to the shops below, and the elevation exhibited is designed with taste, the horizontal girders of the viaduct forming a kind of balcony to the façade. Branched approaches are shown to Harbour-street which is suggested to be widened at the Custom House. The estimate is £31,000. These three last mentioned plans have decided merits, and might, taken with with one another, suggest the bases of a good scheme for bridging the chasm between the cliffs, and connecting the town as well as improving the architectural effect towards the sea. "Well Considered" is almost a daring scheme. It has a front level viaduct about 51ft. high, starting from Rose-hill to a point opposite Railway station, another inland route branching from it to form an inner loop intended to give easy approaches to the town from both cliffs. The drawings are cleverly executed in India ink, and suggest an arcade running along the Viaduct, and the openings of the latter filled with residences and shops, the chimneys passing out through the arcade. The idea

is bolder than desirable, and the strip of houses between the two roads would not be a very pleasing arrangement. "A.D. 1879," adopts a serpentine line of promenade intersecting the streets in the centre of town. The sketch shows a viaduct with sites for terraces and houses between Princes-street and Albion-place, and a narrower roadway connecting the centre streets in the rear. The Harbour-street level is unaltered, concrete arches carrying roadway over York-street. "Percy Britton" adopts a front drive, the West Cliff is arched in front as in other cases, there is a bridge over York-street, the road crossing Harbour-street on the level. Albion-hill is diverted. Prodigious both in scale and scheme is the design of "Viator" No. 2. The plan shows a long front carriage roads or inclines, with descent to the Harbour, the gradients being 1 in 30, and 1 in 22, but no access to centre of town. The cantilever footpaths to widen the roadway along the cliff are certainly ingenious, but we hesitate to call them desirable or even elegant. The face of cliff is relieved by an arcade of pointed arches with a retaining wall above. "Progre diendo Prosperi" is a high-level scheme showing a parade carried by arches over York and Harbour-streets, with inclines as well on each side. In "Economist," the main road is made to skirt the basin, while another branch road from centre of town to the Custom House is indicated upon the Government survey. We can refer only in very brief terms to several others which follow, more or less, the Parliamentary plan. "Non Nobis Solum" exhibits unnecessary labour in indicating the drainage. The road is made to follow the ground-levels crossing over York-street, and crossing on the level Harbour-street, the rise to East Cliff, 1 in 14.5, being fatal to the plan. "Circle and Cross" is a high-level roadway following the line of harbour; houses and shops are shown below the viaduct. "Indicta," also a front retaining-wall and viaduct scheme, just clears the Royal and Albion Hotels, with a road crossing Harbour-street on the level. "Nec Timere nec timide" is a carefully-worked-out design for a semi-viaduct low-level plan, the route being made to clear Crown Hotel, passing behind the Albion. "Camino" spans the valley, and shows steps to quay. It is economical; the gradients are improved; the levels on east and west are unaltered, but the line of roadway is not easy in curvature. "Veritas Vincit" leaves extreme levels, and, like the last, bridges the streets in the centre; but a score of other designs have, for the sake of meeting existing levels, shown a variety of ungraceful bends and right-angled arrangements that perfectly destroy the beauty a marine promenade should possess. Among the best of these we notice "Advance," "Ajax," "Respiece Finem," "Veritas Vincit," "Fido," "Keep on Terra Firma," &c., "Science with Practice," "Tokio," "Artibus et Armis," "Honor Virtutis Premiam," "Thorough," "Industry," "Excelsior," "The Link," "Curve Chemin Passant," "Via Melior Iter Brevius," "Pro Bono Publico," "Silver Streak," "Sphinx," "Q. E. D.," "Z," &c. The Commissioners are to be congratulated on having received such a large number of designs, many of much merit; but we desire to call attention to the points that appear to us necessary to be kept in view in coming to a satisfactory final decision. In the first instance, we hope Ramsgate will not suffer by the adoption of a piecemeal scheme or a niggardly regard to outlay. We think that the plan chosen should be something more than an affair of mere engineering; it should consult the picturesque, or rather the architectural, feeling in the treatment of the new promenade, by uniting the cliffs in a graceful manner, and without destroying the rocks themselves, or turning them into high railway embankments or retaining-walls. A

viaduct, always a pleasing feature, might be easily made to combine effectively with the East and West Cliffs. Beyond this, we consider that preference should be given to those plans that would sweep away the hovels in the centre of Ramsgate, and provide a frontage promenade with branch approaches from the town, those giving easy gradients to the present streets, bridging over the existing chasm in the only possibly dignified manner, and offering a façade to the sea worthy of this favourite Kentish seaside resort.

TEMPORARY BUILDINGS.

THE erection of structures of a temporary kind, at once light, cheap, and portable, is a want that has been strangely neglected by the architect, notwithstanding the numerous demands for such a class of structure and our colonising propensities. It must be confessed that, in spite of the necessities of emigration, our large mining and agricultural population, and our army organisation, together with the use of temporary buildings in the shape of mission houses, churches, schools, and drill sheds, we have not produced anything more satisfactory than wooden and iron buildings of the most primitive description and unredeeming ugliness. It seldom seems to have entered the heads of our utilitarian builders that considerable improvement might be attained if they adopted the materials each country or district afforded, instead of persisting in transporting frames of timber and matched boards after a set specification; and it is surprising to find Government and other contractors adopting iron for the sides of buildings, when timber and concrete are far better and more durable. In the present article we shall first confine our attention to the modes of construction usually adopted, reserving for subsequent remarks a few suggestions upon the subject of temporary erections.

One of the commonest modes of erecting temporary buildings is that of having uprights placed upon brick or masonry foundations at intervals of from 12 to 15 inches apart, boarded on one or both sides, and covered by roofs of the same material. Framed timbers filled in with intermediate posts of lesser scantling make the most substantial walls—the framings, in fact, resemble the framed partitions to houses, with sills, heads, corners, door and window posts, and diagonal braces to throw the strains upon the solid portions of the foundation. The lighter uprights afford a fixing to the outer and inner boarding. Scantlings for the framing are generally about 4in. by 3in., but, for the filling-in, uprights 4in. by 2in. are generally sufficient. These framed sides seldom exceed 8ft. to 10ft. in height, and the lower they are kept in reason the better. The roofs are generally simply framed with collars, the inside lining of matched boards being carried round them. As regards the outer covering to the walls and roof, weather boarding is that generally used. This consists of plain boards, about 3in. thick, laid with a lap joint horizontally, though other forms of making the joints are sometimes used, such as rebating one edge of every board for the lower one to fit into. Roofs are generally of wood, with every alternate board covering the edges of the lower one, or a lap joint following the length of the rafters, or otherwise they are placed close to each other with a fillet over the joint. The latter method is frequently used. Slate, zinc, and corrugated iron are common coverings; but the best roofs are those that are slated upon felt, and the least satisfactory roofs the metal-covered. If we examine one of the emigrants' huts or wooden erections adopted by the War Office, we find it generally a rectangular-shaped hut, divided into two or three parts by partitions running across it,

with centre doorways, the middle division having a door on the outer side with two windows made to light the end apartments, at the same time, the partitions dividing each window into two. The size of hut is often about 21ft. by 16ft., and 7ft. or 8ft. high to the eaves. The centre apartment forms the living-room, and the others the bedrooms. The framing is of red deal 3in. thick, the floor is of lin. boards, and the roof and sides of 3in. weather boarding. The roof is often felted. The houses can be packed in a small compass, and cost about £40 to £50. Cottages of larger size, with four or more rooms, and a lean-to washhouse and pantry, are made in the same manner; and rows of cottages with brick party-walls, each about 22ft. square, with a kitchen or living-room and two bedrooms, each 11ft. by 8ft., leading out of it, are constructed for labourers and miners in districts where no house accommodation can be found. In South Wales and in the mining districts this kind of erection is largely used, the houses being let to the workmen by the colliery proprietors. But they are at the best but cold and comfortless dwellings, though every precaution is taken to render them dry and convenient. A rough rubble wall is built to receive the sills and joists, the framing is covered with 2in. outside boarding and 3in. inside lining. The outside receives three coats of oil paint, and the interior lining is sized, stained, and varnished. The cost of these cottages vary from £75 to £100 each, or from £15 to £20 per square. School-rooms, drill and mission halls, and churches, besides buildings erected for exhibitions and congress meetings, are built upon a similar principle, the framing being about 4in. thick, and the roof constructed of framed principals or upon the excellent plan of laminated ribs; but of all these it must be said, they are never comfortable and always unsatisfactory in appearance, resembling rather huge packing-cases than buildings for human beings. Anything more tasteless, comfortless, and forbidding than the corrugated iron church of the usual type it is scarcely possible to find. Churches and schools of corrugated iron are frequently to be met with, and temporary buildings of this class will always be in request in large poor and populous districts, where permanent church accommodation cannot be provided. As a rule they are of the most stereotyped form and are erected by manufacturing firms upon certain illustrated models, at prices according to size or accommodation. A church for 400, covered with zinc laid on rolls, will cost probably between £700 and £800, though the last figure is nearer the mark. Its size will be about 70ft. long by 30ft. wide. The roofs are generally framed with a collar and iron ties looped up to a king rod, but the scantlings and details are of the most meagre and mechanical description. The temporary churches to be seen in the metropolis are disfigurements to the neighbourhoods they occupy, and are generally so cold and comfortless inside that it would surely answer to erect buildings of a more substantial and slightly character that would draw larger congregations and might be utilised for a similar purpose after they were done with, or turned into schools and club rooms.

In speaking of the temporary church of the usual type, we have pleasure in drawing attention to an improved construction. We refer the reader to a church (All Hallows) that has been erected in Orange-street, Southwark, from the designs of Mr. C. N. MacIntyre North, of the Borough High-street, the whole of the timber framing of which is bolted together, so that it can be taken down and re-erected at a trifling cost. The dimensions of the church in question are 74ft. long, and, exclusive of transept, 26ft. wide. It is of one span, with recesses or transeptal projections for the harmonium

and vestry, and an apsidal end. The roof has framed principals, with collars and curved ribs, which rest on inside square pillars, these latter continuing to the underside of principal rafters, which they help to support, and at the same time form lateral aisle passages. The purlins are boarded in squares, then felted and slated. The walls are of brick, the window-frames are deal, chamfered, with oak sills, and the lights are glazed with lead glazing. Inside, the boarding to roof, and the woodwork generally, are stained and varnished; the church is furnished with chairs, and seats 280 people, exclusive of choir, the total cost, including pulpit, an open, framed screen, seats, and gasfittings, being £691. Externally, Mr. North has treated the building in a simple, unpretending manner, a three-light window, and a small bell-cote bracketed over it, forming the only features at the west end. We consider buildings of this class much cheaper and more profitable than the galvanised iron and zinc buildings in which nave and aisles, clerestories, towers and spires, and other accessories to the permanent church, are reproduced with unmeaning completeness and tasteless detail. Timber-framed structures, filled in with concrete, or tiled externally, might be constructed in a similar manner to that we have described above. We have long desired to draw attention to a few methods by which temporary buildings may be made more artistic. We should begin by acknowledging a general principle, that each locality should furnish the materials necessary where timber is plentiful. We cannot do better than follow the type suggested to us by the earliest dwellers on the Upper Indus, whose dwellings have been so graphically described by Viollet-le-Duc. Unwrought timbers packed together and crossed at the angles, and built on brick or stone foundations, might be made into excellent cottages in districts where wood is plentiful, as skilled labour could be dispensed with; the openings for doors and windows could be roughly framed upon the lower walls, and the roof could be covered with thatch or tiles, the walls plastered with stiff clay or mortar. In places less remote from the appliances of the skilled carpenter, wrought timbers might be substituted for the framework of such buildings; the sides may then be filled up with pise, brick, or stone, or better, with concrete, the materials of which are generally accessible. A species of wattle wall plastered over, or better, lattice-work, might be admirably used as a skeleton framework for cottage walls. We have seen capital cottages built with timber framing filled in with concrete, but we would suggest that blocks of that material cast in the form of hollow bricks, might be used for the purpose. These could be made to interlock with one another. Perforations in the bricks should be left inside to form keys to the plastering, or a lining of matched boards could be fixed to the studwork. We think that these materials combined would furnish a far more comfortable dwelling than one of brick or wood only, which latter dwellings are generally built in the most flimsy fashion; the principal considerations in temporary buildings are—walls that shall occupy little space, can be easily erected, and be thoroughly weatherproof. In fact, the problem of building cheaply and artistically really resolves itself into finding a substitute for brick walls, some material that can be more readily made or transported, and put together by unskilled labourers. Patented systems are, after all, for a time at least, monopolies, and really common-sense and artistic ingenuity have only to be employed together, to arrive at satisfactory results with the methods and materials ready to our hands.

Captain James O'Hara has been appointed inspector under the Local Government Board of Ireland in the place of Mr. Samuel Horsley, resigned.

IMPROVEMENTS IN ST. PAUL'S CHURCHYARD.

CONSIDERABLE alterations are being made round St. Paul's Cathedral, under the direction of Mr. F. C. Penrose, which will have the effect of apparently widening the area round the Cathedral, and removing that gloomy, barrier-like seclusiveness with which our great metropolitan church has been so long invested. One of the greatest of these improvements has been the lowering of the railing of east-iron, the wall that formerly surrounded the churchyard having been recently reduced about 18 inches in height. The railing itself is unquestionably a remarkably fine example of ironwork of the Queen Anne age, and is well worth the examination of all who are interested in workmanship of that period, though we suspect there are few who have really examined it with attention. The uprights form columns, with capitals of Tuscan character moulded below like balusters; the standards at the angles, transepts, and gates are massively grouped in square and circular form. These are being carefully replaced upon the dwarf wall, the whole of the railing having been carefully cleaned and repaired where necessary. In connection with this part of the alterations, we may observe that the eastern corners of the churchyard have been thrown into the road opposite St. Paul's School, and the railing made to follow inverted curves inwards. On the south side the improvement is even more apparent than on the north; but in addition to the reduction of the height of railing, it has been set back about 6 or 7 feet, thereby giving a footpath round that crowded thoroughfare on the south side leading to Cannon-street.

On entering the enclosure, we observe that the churchyard has been altered in its levels, and laid out as a garden, with winding paths, while several groups of shrubs and trees have been planted on both sides of the cathedral. Since Mr. Penrose read his interesting paper at the Institute, a report of which we gave at the time (see pp. 132, 183 of present vol.), one or two remarkable discoveries have been made. On the southern side a further clearing away of soil has revealed the outer south-east angle of the cloister, and a portion of the surrounding passage is now cleared and bared to the pavement, the diagonal squares of which, of Purbeck marble, may be seen. The remains of the buttresses and of wall shaft bases to the cloister have been thoroughly exposed, and appear as crisp as when first executed, in some parts. The responds, with their octagonal bases and mouldings of Purbeck marble, are clearly exhibited, and the plan of the shafts themselves can be made out. These are small engaged clustered shafts, separated by hollows. Mr. Penrose has attributed this work to the end of the 14th century, though the character of the mouldings would seem to indicate to us a later date. We refer to a plan we gave, page 183. *ante*. Excavations carried on at the north-east angle, in pursuance of the scheme of exploration of the architect, have been rewarded recently with a still more important discovery, that of the foundations of St. Paul's Cross, a result which Mr. Penrose never despaired of. The foundations of this famous cross have been discovered at the north-east angle of the choir, and are partly covered by the present building. A plan we have seen makes the out-to-out dimensions about 33ft., or those of the circumscribed square. If we range the line of the eastern side of the choir on the outside, that is the square portion of it, the octagon projects about 10 to 12ft. eastwards; but the axis of the octagon is not parallel with that of the cathedral, but slightly divergent westwards.

This discovery will be hailed as a very important link by archaeologists, connecting as it does the most memorable period of our history with later times. St. Paul's Cross we read of as early as 1259, in Henry III.'s reign, as a town preaching cross; it was associated with some memorable occurrences, as the penance of Jane Shore, Dr. Shawe's infamous sermon, the fulminations published against Luther, but its chief interest resides in the fact that from its pulpit the earlier Reformers preached their sermons, and it was used for preaching till 1643, when it was demolished by order of Parliament. The earlier prints of St. Paul's Cross show it as a small octagonal structure of wood, raised upon a platform of three steps of the same form, with a pulpit projecting from one of its sides. Seats surrounded it. It is proposed to mark the site of the cross by a pavement, so as to distinguish its position for all time, and we heartily commend the idea. The other portions of the churchyard on the north side are being laid out with paths. A fountain of circular shape is to be placed in the space between the transept and the eastern extremity of the cathedral, close to the site of St. Paul's Cross, and the foundations have already been prepared for this purpose. These discoveries and improvements, due to the untiring energy of the Dean and Chapter and their zealous architect, will convert St. Paul's churchyard from the neglected and gloomy condition in which it has so long remained into an attractive centre worthy of the edifice. We may only express the wish that a still greater improvement, long talked of, will some day supplement these efforts by the setting back of the property on the north side and the rebuilding of the frontages, and we are sure the cost of purchase and compensation would be quickly defrayed by the larger rents an improved frontage would acquire. It may also be interesting to archaeological readers to know that the recent conclusions drawn by Mr. Penrose from the excavations have to some extent been modified by recent disclosures, and that that gentleman shortly hopes to solve in a more satisfactory manner the enigmas recently discussed in his paper read at the Institute, and to which we have referred.

HISTORY AND ÆSTHETICS OF ARCHITECTURE.—II.

ROMAN architecture, its development and characteristics, formed the subject of Mr. Statham's second lecture at the Royal Institution, delivered last Saturday afternoon. The buildings erected by the Romans were, the lecturer observed, more interesting from their historical connection than for their intrinsic architectural merit, inasmuch as they formed the great link between the Antique and Mediæval worlds. From an æsthetic point Roman architecture was far inferior to that of the Greeks. The chief traces of the origin of Roman architecture were found in the remains of that mysterious people the Etruscans, of whose art and life recent explorations had given us some idea. Amongst Etruscan remains had been discovered some of the same forms that existed in Egypt, from whence, perhaps, about 1500 B.C., art fashions seem to have spread over the civilised world. The resemblances between the smaller Egyptian and Tuscan temples were indicated by means of typical ground plans placed side by side; each, it was shown, consisted of three compartments, with internal pillars. The Etruscan mode of building was known not only from its monuments but also from the works of Vitruvius, an architectural writer who lived presumably about the Augustinian period, and from whose works we are able to reconstruct the Tuscan order with exactness, although not a single original building remained. In the Tuscan order might be detected an unmistakeable reminiscence of wooden architecture. The beam laid upon the columns was very thin, and those were slender in proportions for a stone construction, although excellently adapted for use in a wooden style. The architrave exhibited a

characteristic shallowness, and the order was almost devoid of ornament. A good example of revived Tuscan might be seen in the church of St. Paul, Covent Garden, originally built by Inigo Jones. Another feature of Etruscan architecture, which influenced that of Rome to the latest date, was the occasional employment of the circular form for temples, the round form usually being capped by a low conical roof. In some cases, too, tombs were built with the false arch opening only found in very early periods of art; an opening in which the stones were laid horizontally, but so arranged as to lap over more and more at each course, and thus form a triangular head, which had the appearance of an arch while constructionally it was not. In his former lecture, he had mentioned that the Corinthian order would be more correctly regarded as a Roman than as a Greek order, for it was but rarely used by Greek architects, its great development and fullest use being made by those of Rome. A very fine example of the order was the three columns still standing in the Forum of Rome, and now known as the remains of the Temple of Castor and Pollux, although for ages they were designated as part of that of Jupiter Stator. On comparing the order as developed in Rome with that of Greece a very important difference was apparent, and one which in principle distinguished the art of the two nations in every feature. This was the larger amount of surface ornament, and the want of constructional application in the volutes. They were by the Greeks brought under the angles so as to carry the weight; whereas the Romans turned them forwards, where they had no business to be, for the purpose of display. This want of skill and tact was also exhibited in the Ionic style. In Greece Ionic columns were only employed between pilasters, the reason being that they were intended to be seen from in front, where the delicate curves of the volute would appear most satisfactory; they would seem to add strength to the abacus, and were highly ornamental. The Romans used the Ionic column at angles and without pilasters, the consequence being that the volutes did not present an agreeable appearance when viewed sideways; they therefore twisted the volutes obliquely, so as to resemble horns, with the result of greatly detracting from their beauty and effectiveness. Another difference between the art of the two nations, in which the distinct inferiority of the Romans was apparent, was in their methods of decoration. He should have mentioned last week that it had been recently discovered that the Greeks decorated their principal buildings in colour—not in glaring primary washes over a broad surface, but in conventional patterns of repetition, applied in outline to the marble surfaces of frieze, architrave, and other parts of the temples. This subdued use of polychrome was not vivid enough for the Romans. They had no idea of subordination of parts and of decoration, no conception of the fact that a given ornament might be worth painting but not worthy of carving. They had enormous wealth and wished to display it, and so they cut ornaments upon their mouldings mechanically and in profusion. Greek ornament was an architectural intellectualism; that of the Romans was executed to display the means at the command of the builder. This was easily achieved; the whole building was covered with flabby ornaments, testifying to a good deal of work, but to very little taste or thought. The Greek artist seemed to have an intuitive perception of what was necessary to give a building its highest tendency; the Roman desired to put on the building as much costly ornament as he could. The constructional distinction between the architecture of the two countries was the introduction in Roman work of the arch. The Greek was exclusively a trabeated style; the principle on which its openings were formed was that of upright stones with a lintel resting upon them. Since the texture of stone is granular, this was the very worst mode of employing that material, as the lintel was subjected in the centre to cross strain, the force which it could least efficiently resist. On the other hand, it was a stable form of building, for if the stones could bear the weights resting on them, and were undisturbed, each triliton would stand to all time unsupported by its fellows. The Romans used stone in its strongest capacity, that of resisting compression, for their openings, building up the masonry in the wedge form of an arch. By this means, wider spaces were bridged over; but while the

arch could not fall inwards, it had the disadvantage of ever thrusting laterally, and frequently, from neglect of buttresses and foundations, the archespread outwards, and the building became a complete ruin. But the Romans, while building in an arched style, continued to imitate lintel construction, the simple reason why they did this being because they were stupid. When they put up a triumphal arch, as in that of Septimius Severus, they added to the faces of the piers columns, and architraves, friezes, and cornices, and since they found that the columns were supporting nothing, and that the arches did the duty, they brought out a section of the superposed architrave, frieze, and cornices over each column. They did not think about the reasons for their decoration, but regarded an order as a cheap way of getting "art." They ignored the fundamental rule in æsthetics that the external design should be the expression of the construction. Hence in the Baths of Caracalla as restored on paper by M. Viollet-le-Duc, there is a series of great arches enclosing a court, having a column attached to each pier and above it an architrave, frieze, and cornice, then a statue in a niche and another architrave, frieze, and cornice. If you visit Rome you will find that all these falsely-applied ornaments have fallen away, leaving standing the arches, in which you can see the cavities in which the column, statue, and horizontal members were fixed. That which was essential in the construction remains; the mere shams have perished. Still more extraordinary differences between Greek and Roman architecture were in the purposes and dimensions of their buildings. Greek remains consist almost entirely of temples, and only one of these was much larger than an ordinary parish church. They are executed in the finest materials, and are exquisite in workmanship; the architects seem to have put up a few ideal buildings. On turning to Roman works one sees a complete contrast. Their temples were comparatively small, but they had enormous buildings for public purposes, such as theatres and baths, as well as aqueducts and other engineering works; buildings of great size and many varieties, but no one of which would be regarded as perfect. The Greek buildings were but few and of one class, but these were of unsurpassed beauty. A typical Roman building was the Colosseum, which was almost exactly three times the size of the Albert Hall, and half as high again. It was decorated with the usual strings of columns, pilasters and orders, piled one above the other, and these illustrated one point wherein the architecture of Rome excelled that of Greece—viz., in affording the spectator an adequate impression of the size of a building. This was accomplished by a multiplicity of parts of similar scale. If a number of Greek temples were drawn of a uniform size, little difference would be found between those of the same order, except that in the larger examples subtle refinements of curves were introduced for optical effect, which were quite unnecessary in the smaller ones. This one point was better understood by the Romans. By using a series of uniform arches the impression was at once conveyed that a building was a great one. Again, the Romans were anxious to provide for cities ample supplies of water, and these were conveyed by means of aqueducts carried by arches across valleys. For these the columns and other applied decorations were discarded, and the result was that these were the most satisfactory of Roman buildings, as they alone exhibited a complete correlation between purpose, plan, and construction. The principle had its application at the present day. We were constantly building in imitation Gothic and bad Renaissance; but our engineers, when they were able to keep their hands from architecture and simply designed a utilitarian fabric, produced a genuine and therefore satisfactory building. Some time before the year 309 A.D. the Emperor Dioclesian determined to build a palace at Spalatro, and seems to have employed a clever architect to design it. It occurred to the architect that part of the Greek architrave might be treated as part of the arch, and it therefore followed the outline of the arch as a moulding, instead of being a distinct line above it, and this was one of the beginnings of a true arched style. He had alluded to the circular tombs of the Etruscans. The form was retained and developed for these monuments; very interesting examples being the tomb of Cecilia Metella, built about forty years before Christ, and that of another at Tivoli of about the same date,

erected on an Etruscan site. In the latter case, a tier of Composite columns surrounded a solid cella, or more properly a vault. In the Pantheon this circular form was rather developed, but the colonnade had entirely disappeared, and in the walls were discharging arches to carry the weight to the most stable part of the foundations; but carefully concealed, however, from view, as if the builders were ashamed of the constructional necessities of the fabric. The change of the seat of government from Rome to Byzantium had a lasting effect on the architecture as well as the history of Western Europe. In Byzantium the dome was gradually developed in character and importance, and adjuncts of aisles, transepts, and apses were added to the original cone. Having a round building, it was easy to add a domical roof; with the octagonal form it was still comparatively easy, the angles being corbelled over. But a square building presented a real difficulty to the architect. The first step was to make a strong central ring, resting on the walls at four points, from which the dome should spring. The angles were supported by throwing beneath each a segment of a subsidiary domical vault, and the thrust of these being adequately met, a firm basis was afforded for the dome. Mr. Statham announced that in his next lecture he should deal with the development of Byzantine into Gothic architecture.

THE ART OF THE ITALIAN RENAISSANCE.

ON Saturday afternoon Dr. Todhunter delivered the seventh of his course of lectures on the above subject, in the New Buildings, Trinity College, Dublin. The lecturer said that coming from Michael Angelo, the supreme sculptor of the Renaissance, to the Venetians, who in all the qualities of fine painting were its supreme masters, was like descending from lofty peaks to bask in pleasant meadows, and wander through enchanted groves. The first painter of the Venetian colour school to whom he would refer was Giorgione, whose very name sounded richly on the ear, and filled the eye of the imagination with a vague delight of gorgeous Venetian colour—that full-toned colour which glowed with the warm splendour of sunset or of a twilight soft as that which might fill the chambers of some palace of the genii, where the glare was mellowed through amber windows. But Giorgione was now little more than a name to conjure up pleasant dreams, a legendary personage whose works had perished from the earth to live only in the imaginations of men. All the frescoes with which he adorned the fronts of buildings in Venice were utterly gone with the exception of some very few mouldering fragments which still clung to the walls. But the impression which Giorgione produced upon the men of his time was shown by the multitude of imitators of his style. Some twenty painters set themselves more or less deliberately to paint pictures, which were easily mistaken for his. In Giorgione they saw for the first time a man whose art was almost divorced from religion, and who frequently painted subjects which were not even legendary or mythological, but simply ideal transcripts from the life around him. The beauty of life and the interest of everyday incidents were now at length recognised by the Venetians, and hence the crowd which pressed into the wide field opened by Giorgione. The influence of Giorgione was clearly visible in the works of several painters. With respect to Titian, he was as manifestly the representative Venetian painter of his day, as his master, Giovanni Bellini, was of his. Born about the year 1477, he seemed to have felt the glory of landscape scenery as probably no painter ever did before. He completed that fine treatment of landscape as something more than mere background which was begun by Bellini and Giorgione. In 1516, when he was thirty-nine years of age, Titian was fairly recognised as the great Venetian painter. He moved in the most cultivated society, and was in great request as a painter of portraits as well as of subject pictures. He lived to the age of ninety-nine. His long life had not the personal and political interest of that of Michael Angelo. He was the prosperous, aristocratic painter of a wealthy city whose national prosperity was at its height, while its spiritual decline had begun; and his art shared to some extent in that decline. In his works there did not appear the same undeniable advance from first to last as was observable in

Bellini's; yet up to his eightieth year he showed little signs of decline in skill. A picture which he painted for his own pleasure a few years before his death was hung up as a model of all technical excellence in the studio of Tintoretto. In the spirit of his works, however, a feverish inequality appeared. He became the flatterer of princes, and painted multitudes of pictures which pandered to the lower tastes of such men as Philip II. of Spain; yet, at the same time, he occasionally did magnificent things, and at his lowest was always a great painter. His portraits would always hold the very highest place, though he frequently flattered his sitters by idealisation, as in the case of the ugly, awkward, and sensual Philip, whose likeness, as put by Titian on canvas, won the heart of Mary of England. Titian's "Bacchus and Ariadne" was one of the greatest works of his best period. Any adequate description of it would require poetry rather than plain prose, suggested, as it was, by a poem of Catullus, and itself no doubt the origin of Keats' "Endymion." It was indeed quite in the spirit of Keats, classical in the sense in which his work was classical, steeped in the sunshine of Greek mythology, yet with a richness of tone which was essentially modern, and which was called Romantic rather than Greek. Ariadne, abandoned by Theseus in the island of Naxos, was portrayed as surprised by Bacchus as she stood gazing out to sea after the retreating sail. Bacchus in his chariot drawn by leopards, and surrounded by satyrs, appeared rushing out of a forest glade and flinging himself from his chariot in impassioned pursuit of Ariadne, who turned to fly at the first surprise of his sudden advent.

SCULPTURE IN GOLD AND IVORY.

AN interesting paper on "Sculpture in Gold and Ivory" appears in the *Magazine of Art* for May. We have, remarks the author, not so much as a fragment of any of these wonderful chryselephantine statues of ancient Greece remaining, nor have we more than scanty notices of how they were put together, and what they were like. The general tendency of modern theories leads to the conclusion that though the materials of which sculptors make use should be of fine grain and pure whiteness, such as Pentelic or Parian marble, yet that little reliance is to be placed on the splendour of mere material, and that the mind should be directed rather to the deep and imaginative beauty which the artist has embodied in his sculpture. Statues of gold and ivory are to some extent in contradiction to such teaching, true as it is when broadly stated. There were many of these chryselephantine statues in ancient Greece. The most famous were those of Zeus (Jupiter), at Olympia, of Here (Juno), at Argos, and of Athene (Minerva), at Athens. They were of colossal size. That of Zeus was from fifty to sixty feet high, on a pedestal of twelve feet. That of Athene was perhaps forty feet (twenty-six cubits). They have been described but vaguely by various authors—by Pausanias, who saw these as well as many others in the second century of our era. The faces, arms, legs, and all uncovered portions of the limbs were of ivory; the dresses which hung, in the case of the Athene, in straight but ample folds to the feet were of gold, the borders and edges were highly wrought. The Zeus sat in a chair (such, probably, as some seated statues in the British Museum are provided with) made with massive square bars and backs; at the four supports of which stood four Victories. In one hand he held a life-sized Victory, in the other a tall sceptre surmounted by his emblematic eagle. The sceptre was of various metals; the throne, or chair, was of cedar-wood, inlaid with ivory, ebony, and precious stones, and had on it figures and groups in relief. The footstool of the god stood on four lions, and the pedestal on which the whole was raised was covered with figures in relief.

The Athene in the Parthenon was standing. The face, arms, and feet were of ivory. The eyes were of marble, or *pietra dura*. On the head was a helmet, surmounted by a sphinx in the round, with griffins on either side in relief. Contests with centaurs were executed in relief on her Tyrrhenian sandals. She held a spear in one hand, and a life-sized Victory, considered a work of extraordinary beauty, in the other; and had a shield and a serpent at her feet behind her. She wore an aegis, or breast-plate of gold, on which was a Medusa's head of gold, replaced,

when Pausanias saw it, by one of ivory. The shield had the battle of the giants on the inside, that between the Greeks and the Amazons on the outside; and in this part the portraits of Pericles and Pheidias himself were ingeniously introduced. This fact led to a subsequent accusation of impiety. On the pedestal was the birth of Pandora.

The gold on these statues was hammered, and of no great thickness; said to be "a line"—perhaps as thick as the eighth of an inch. The throne of Zeus has been already said to have been of cedar. An olive-wood and cedar frame was the structure on which the Athene and other such statues were made up. There remain on coins various typical representations of the Zeus and of the Athene, and there are in the Museum of Naples, and the Vatican, antique statues considered to represent them (see "Museo Borbonico," vol. iv., plate 7, for instance), and the Pallas of the Villa Albani. A bust of Zeus, with huge locks of hair, in the Museum of Naples, is also considered to represent the head of the colossus at Olympia. All the great artists who were contemporaries or pupils of Pheidias worked at the statues we have described, or took special parts, such as the inner and outer sides of the shield, the sandals, pedestals and so on. The golden drapery of the Athene seems to have been so laid on that it was movable; at any rate, the artist had it taken off and weighed when accused of peculation. The entire weight of gold was about forty talents, and the value in our money was about £120,000 sterling—a great sum in those days.

The question will naturally be asked, how such surfaces as a face nearly five feet high—or in the case of the seated Zeus twice as large—the arms, and limbs, could possibly be made of ivory? The material was laid on olive-wood, and was probably glued down with excellent animal size (in the opinion of De Quincey, pegged down to the wood). However large the teeth at the artists' command, the pieces must have been joined. The ancients are said to have been acquainted with methods of softening the edges and joining together slices or slabs of ivory something in the way in which tortoise-shell is still joined. Oil was constantly rubbed or poured over the Zeus to preserve the ivory, and the vapour of water had a similar effect on the Athene in the Parthenon. It must be remembered also that, in consequence of the immense scale on which these statues were made, the lines or cracks that might be seen on small carvings close to the eye would not be generally perceptible. There remains one more question regarding these sculptures: was the ivory left white or painted? We know that the architecture, probably also the sculpture, of the Parthenon was painted and gilt. Were not most of the statues of the Greeks painted also? If the eyes of the Athene were inlaid in marble, or lapis-lazuli and other stones, was her face left without colour? We have no definite information on this point, but there is some probability that even the ivory may have been treated with colour laid on with size or wax. Such a treatment would tend to preserve the material, and we know that these large statues remained entire in the second century of our era, and were probably, not taken to pieces till the fourth.

The example set by the artists of the time of Pheidias was followed in a number of sacred places in Greece, and it became a sort of fashion to have such statues in the rich temples of the Roman dominions. Numbers are said to have been made in Athens, Corinth, and other wealthy Greek capitals, for exportation long after the loss of Greek independence. We must not omit a notice of an effort, the only one that can be mentioned in modern times, to revive this costly kind of sculpture. The late Duc de Luynes had a statue of ivory, silver, and bronze, a Minerva, made by a French sculptor, M. Simart. It was exhibited in Paris in 1855. It measures nearly 10ft. in height. The face, neck, arms, and feet are of Indian ivory, as well as the torso of a small Victory held in her right hand, and the Medusa's head on the aegis. The spear, shield, helmet, and serpent are of bronze; the drapery and the aegis, or breast-plate, are of beaten silver, carefully chased with the graver.

We have no record of any similar attempt during the Italian Renaissance, that period so fruitful, not only in excellent sculpture of bronze and marble, but in the production of carved ivory,

CUR COMMONPLACE COLUMN.

GRANITE: DURABILITY AND USE.

IF the granite contains much quartz it will be hard to work; but unless the felspar is of an inferior kind it will weather well. The *potash* felspar is more liable to decay than the lime and soda felspar (*allogelase*). Mica is a source of weakness. If there is an excess of lime, iron, or soda in the mica or felspar the granite is liable to decay. *Working*.—The smaller the grains the better is the granite for building purposes, as the more easily can it be worked. Mr. Wray in his work on Stone, says, "In using granite for ornamental purposes the coarser-grained stones should be placed at a distance from the eye, the finer grained stones where they can be easily inspected. Without attention to this point very little better effect is produced than by a stone of uniform colour." For plinths, copings, architraves, and public doorways, and for those parts and structures exposed to rough usage or wear granite is a valuable material. For engineering purposes it is a most useful material for bridges, piers, quay-walls, paving, &c. The surface of granite is entirely destroyed by the effects of fire. *Varieties*.—The Scotch granites from the neighbourhood of Aberdeen are highly esteemed; the best known are those from Peterhead, Rubislaw, Stirling Hill, Dalbeattie, Ross of Mull, Kennay, Kinsteary, &c. The Devonshire and Cornish granites have not so good a name. Guernsey granite is chiefly used for paving purposes. See "Notes on Building Construction," Austed's "Practical Geology," and our own articles on "Architectural Geology."

Granite is a silicious stone of a highly crystalline structure, consisting of grains irregular in appearance and variable in composition. The principal ingredients are quartz, felspar, and mica, combined with hornblende and other minerals. When the felspar is present in large and distinct crystals, it is termed porphyritic; when the mica is replaced by hornblende it is termed syenitic granite. The colour of granite—usually red or grey—depends on the ingredient that predominates; the prevailing tints—either white, red, or brown—are due to the nature of felspar present. *Uses*.—The density and hardness of granite render it difficult to dress; its use is, therefore, chiefly confined to the facing of important buildings, and for bridges, piers, aqueducts, docks, &c. Durability, being the most important consideration, will depend (1st) on the quantity of quartz present in the stone, the quartz being imperishable; (2nd) on the nature and quantity of felspar; this mineral sometimes decays very rapidly on exposure, forming a kind of white clay used in making porcelain ware; (3rd) on the proportion of mica present, being easily decomposed when present in large quantities. Iron, when present in any quantity, also causes stains, &c. When the crystals of the various minerals are small, hard, compact, and well diffused, with a bright surface, the stone is usually found to be durable. Generally speaking, granite shows no planes of stratification, and can be worked equally in any direction. When granite is used for ashlar, it is more economical to have it dressed at the quarries; the stone becomes harder when exposed to the air, therefore easier to dress when freshly quarried. The workmen are more accustomed to the work. The superfluous material being cut off, the stone is lighter, saving carriage, its hardness preventing clipped arrisses when ordinary precautions are taken during removal. The chief supplies are obtained from Cornwall, Devon, and Cumberland; Aberdeen and Inverness, in Scotland; the Wicklow and Mourne Mountains, in Ireland; the islands of Guernsey and Jersey.

"J. D. B." sends the following notes: Chemical composition of ordinary granite is generally as follows:—

Silica	72.3
Alumina	15.3
Alkalies	7.4
Lime, magnesia, and iron ..	5.0

100.0

This rock consists generally of about 40 per cent. of felspar, 30 or 40 per cent. of quartz, and from 10 to 20 per cent. of mica. Specific gravity of ordinary granite is 2.66, a cubic foot weighs 166.2lb., and a cubic yard as nearly as possible 2 tons, about twice weight of cubic yard of coal. Granite contains about 0.8 per cent. of water, and is still capable of absorbing $\frac{1}{4}$ more, or about

0.2 per cent. This water is contained in minute cells in the quartz. In specification say "no rusty veins," these are of iron, and so rust and leave crack. On the Continent granite frequently appears, St. Petersburg being largely built of it; the largest block at St. Petersburg as pedestal of Peter the Great's statue 50 cubic yards of material. Granite not decomposed by acids, and only imperfectly and slowly calcinable at a great heat. Some say carbonic acid in rain water decomposes felspar, thus leaving mica and quartz without any cementing material. China clay or kaolin said to be decomposed granite.

GRATES.

A good grate, in which economy of heating is aimed at, should be shallow in depth, about 9 inches at the bottom, sloped upwards. It should not be so low as ordinarily seen in some fashionable patterns, but at least 9 inches from hearth. The principles of construction have not been discussed with greater ability than when Comt Rumford wrote upon the subject, though numerous claimants have appeared. The principles then inculcated in respect to the form of the sides and back and the use of fire-clay have been adopted by a score or more of manufacturers of late years with undoubted results. The ventilating stove is the outcome, but it is unnecessary to name the numerous varieties and patents before the public, all of which have some form or other of heating chambers or air flues, either behind, or at the sides, or both, by which the air, admitted direct from the outside, becomes heated and is allowed to escape at the sides or above the grate. We may mention Sylvester's, Dr. Arnott's, the "Galton" stoves as exemplifying the principles that have been aimed at by various makers of grates. Fire at both their backs and sides is universally adopted. A length of bar equal to 1 inch for every foot of length of room, and the height $\frac{1}{2}$ inch for every foot of breadth of room, is a useful approximate rule for size. The "Manchester," Messrs. Barnard's, and other forms of slow-combustion stoves noticed in our pages are recommended. (See our advertisement pages.)

GREEK ARCHITECTURE.

As to the origin of Greek architecture it undoubtedly owes much to Egyptian and Asiatic influences, the earlier types being corrected by the laws of æsthetics. Greek architecture passed through four phases. First, the timber was only material of construction, whether we accept or not that "the Doric triglyphs represent the ends of beams scored with grooves for ornament." In the second phase wood covered with metal was chiefly used. This is undoubtedly of Asiatic origin. Then stone, including brick, tufa, and granite. And lastly, marble was their chief material. The three styles in which Greek architecture developed itself are the Doric, Ionic, and Corinthian (see articles under respective titles). The Doric is considered by some to have passed through six phases, the first or proto-Doric dates anterior to the seventh century B.C., and the last belongs to the fourth century (see metope in the Schliemann col., S. Kensington Museum). The chief characteristic of the Doric order is its proportion, its massiveness suits it particularly for its object, the square abacus forming an easy support to the entablature. If we accept the general law that an object is most æsthetic when best suited to its end and purpose, the Doric order is then the most artistic. The Ionic order is chiefly characteristic of symmetry. The volutes are of Egyptian (or Assyrian) origin. The Corinthian order is distinguished by its curiitany. The foliated capital is a development of the Egyptian lotus capital. If viewed strictly the Corinthian capital is a breach of the laws of æsthetics, for drooping leaves can never suggest support. It must be noticed that the deity to whom the temple was dedicated greatly influenced its style or mode of building. Temples dedicated to Zeus, and to male deities in general, were heavy, solid, and plain. Those dedicated to Athene and other goddesses were light, elegant, and highly decorated. This is not a passing fancy or mere sentiment, but an actual fact, which only requires careful observation to be verified. The architecture of Greece was essentially public, and hence they possessed no domestic architecture (we speak of Greece in her ascendancy and golden age). "Such was the spirit of patriotism that the richest citizens did not endeavour to exceed others in the magnificence of their houses or tables, but employed their wealth for the security and defence of their country, and in

raising noble buildings and works for the service of religion, and in honour of public and private virtue."—C. F. W.

GRANGE.

"C. F. W." sends the following notes:—A grange, according to Prof. Parker, is a farming establishment, especially such as belonged to a monastery. From M. Viollet-le-Duc we learn that they were originally built by the monks, usually within the precincts of some abbey. They were very numerous and well-built. Some of them still remain in the Ile de France, Normandy, Champagne, Touraine, dating from the 12th and succeeding centuries. Their plan is usually of three parallel lines, divided by two rows of pillars, which support the heavy framework of the roof. They were sometimes protected by watch-towers, and were inhabited by serving-monks and peasants. They then had certain dwelling-rooms, and here any benighted traveller could find a lodging. By degrees these granaries or granges were grouped around the dwellings of the peasants, and thus became the origin of hamlets. In times of danger the peasant betook themselves to this inclosure, and were thus better able to defend themselves. These monastic granges were often destroyed by neighbouring rival abbots. These granges sometimes contained stables with a vast loft or granary above. There is one of this kind still remaining at St. Martin au Bois (Oise).

GREENHOUSE.

A greenhouse is a house with glazed roof and sides in which plants are kept in pots; it is generally built on the ground floor, either attached to the house or disconnected. The flower-pots are usually placed on wooden stages in the centre, on shelves along the side, or upon the brick casing the pipes or flues. Greenhouses, unlike hot-houses, are intended for the plants of climates only a little warmer than our own. A temperature of from 45° to 50° only is necessary, and this may be attained by a smoke-flue or hot-water pipe. The best aspects are south and south-east, the north is the worst. The great object in construction should be to allow the plants to catch the rays of the sun, and this may be done by fixing the shelves so that they may follow the slope of glass roof. The reader is referred to the works of Paxton, London, and others for details, also to our own pages.

CHIPS.

A National Exhibition of Ecclesiastical, Architectural, and Decorative Art will be held, under distinguished patronage, at Swansea, in October next.

The Annual Congress of the Social Science Association, to be held at Manchester, will open on October 1 and close on October 8.

Mr. Alfred Robinson, Church and Art Furniture Manufacturer, has removed from 173, High Holborn, to 54 and 55, Broad-street, Bloomsbury.

On Tuesday week the new schools erected by the West Bromwich School Board were formally opened. Theschools and class rooms, with offices, will accommodate 250 boys, 170 girls, and 200 infants. They are Gothic in style. The work has been successfully carried out by Mr. Henry Smith, of West Bromwich, from designs of Mr. John Loxton, architect, Wednesbury, and the cost, including site, furniture, fittings, &c., will be between £6,000 and £7,000.

A new Wesleyan chapel at Stannington was opened last week. It is cruciform in plan, the length being 53ft. and the width 31ft.; the transepts are 20ft. wide and 10ft. deep; the height from the floor to the springing of the roof is 18ft., and to the centre portion 21ft. It is designed in the Romanesque style. Accommodation is provided for 200 adults and 200 children, and total cost has been £1,500. The work has been carried out from the plans of Mr. H. W. Lockwood, architect, of Sheffield.

St. Peter's Church, Pickering, the restoration of which is nearly completed, under the direction of Mr. J. S. Crowther, of Manchester, will be reopened on the 10th of June.

A new Congregational church at Tunstall is completed. The building is calculated to seat from 450 to 500 persons, and the cost of the erection when quite finished will be between £1,400 and £1,500. We may add that the contractor for the erection is Mr. Yorke, of Tunstall.

Lord William's Grammar School at Thame founded in the reign of Queen Elizabeth, was opened on the 1st inst. in new and substantial school premises erected from the designs of Mr. Williamson, of Oxford. Messrs. Taylor and Grist, of Birtton, near Aylesbury, were the contractors, and Mr. Burton was the clerk of works.

OUR LITHOGRAPHIC ILLUSTRATIONS.

CARLYLE HOUSE, CHELSEA.

THIS detached mansion, our view of which is reproduced from that in the present R. A. Exhibition, has been erected on one of the most interesting sites of the Victoria Embankment, Chelsea, forming part of a block of west-end houses recently erected adjoining the Botanical gardens belonging to the Apothecary's Company, commanding an extensive view of the Thames, and being immediately opposite Battersea Park. The style is "Queen Anne," and the front has been executed in red brick, with rubbed and gauged mouldings, and carved panels, the back elevation being in stock work, with red brick dressings and mouldings. The plan has been most carefully considered with view to convenience and comfort, introducing every modern improvement in ventilation, warming, and prevention of sound, special attention being paid to the drainage, which has been laid outside the house. The plumbing work has been executed upon a system found to be the most perfect after many years' experience and study of the subject by the architect. The whole of the waste pipes are entirely separate from the soil pipes, the supply of cold water is filtered before leaving the cistern, and there is a separate supply for the supply of the water-closet apparatus. Full control over the pipes is given by stopcocks in case of frost. The house is warmed by means of coils of hot-water pipes placed in the vestibule, hall, staircase, lavatories, and the large fernery or conservatory, adjoining the boudoir. The heat at each coil can be readily regulated by gun-metal screw valves. These coils are heated from a boiler of the most sure and improved make placed at the base of the back staircase, with the several floor and return pipes traversing the basement corridors, thus warming the air, and encouraging a draft up the back staircase, at the top of which is fixed one of Hill and Hey's ventilators. Each room, with the exception of

one or two of minor importance, has a separate ventilating flue, built between the flues from the fireplaces, but in no way connected with them, and a special ventilating flue is provided from the kitchen. The water-closets are also ventilated. A complete system of hot-water supply is carried out from the kitchen (which is one of Hayne's improved projecting closed range and hot plate combined) to the hot closet on the third floor, with branches to the two baths, nursery, scullery, housemaids' closet, lavatories in bed rooms, with shampooing apparatus, lavatories on the ground-floor, and also to the butler's pantry. One most important feature in the house is an improved hydraulic lift, the first of its kind erected in England. This has been fixed from the basement to the third floor, acting as a passenger or luggage, as well as a dinner lift, the apparatus of which is perfectly safe, and so simple that the most inexperienced person can use it at any speed desired, without the slightest danger, and the cost of the water for its use is only about £5 per annum, a constant supply being laid from the company's main. The principal staircase is constructed of pitch-pine from ground to second floor, and a second staircase connecting the suites of bedrooms on the second and third floors, and from the third floor to attics, also a back staircase of stone from the basement to the third floors communicating with each landing. A billiard-room is formed under the schoolroom, with a private staircase from the principal staircase. In the rear of the house, a complete block of stable buildings for the accommodation of four horses, and standing room for three carriages, with residence for coachman, has been erected, the entrance to which is in Queen-street, but so arranged that while they form a picturesque object from the back of house, they do not in any way interfere with the clear view over the garden, from which they are entirely shut off, a private door only being provided from the garden. The stables are built upon the most approved plan, and with the latest improvements in fittings, &c. A washhouse and laundry have been formed in the stable buildings, fitted with large washing trays, supplied with hot and cold water, and all necessary fittings. The laundry is supplied with a hot closet, and galvanised iron drying-horses, large ironing-stove, with hot-water apparatus complete. The mansion has been carried out from the designs and under the superintendence of Mr. A. Croft, Messrs. Gillo, of 176, Oxford-street, being the builders.

TWO ITALIAN TOWERS.

VITERBO is a very picturesque city, and full of interesting subjects for sketching. It is celebrated for fountains, and there are many external stone stairs to the houses, of great beauty. It is a hilly place, and the campanile of S. Giovanni is down in a hollow, and was sketched from a place above the church. There is a good campanile to the Cathedral, somewhat like this one, but larger. Prato, a small town between Pistoja and Florence, is best known for the very fine frescoes in the choir of the Cathedral by Filippo Lippi; there are also some by Agnolo Gaddi, a good circular pulpit by Rossellino and Mino da Fiesole, and outside is the pulpit with Donatello's dancing children at the angle of the building. The campanile was sketched from the cloisters of the church to which it is attached, but I do not know the name of the church.—P. J. MARVIN.

NEW DIVINITY AND LITERARY SCHOOLS AT CAMBRIDGE.

THE late Professor Selwyn founded a fund for the erection of a Divinity School at Cambridge, for which the University purchased a site opposite the front of St. John's College, and having a considerable frontage towards the open space of ground known as All Saints Churchyard (the church had been removed some time since). This site being of more than adequate size for the Divinity School, it was decided to erect upon it certain lecture-rooms for the literary professors also. Three architects, all graduates of the University of Cambridge, Mr. A. W. Blomfield, Mr. Gilbert Scott, and Mr. Basil Champneys were invited to send plans in competition, and the plans of Mr. Champneys were selected. The contract was undertaken by Mr. J. Loveday, of Kibworth, near Leicester, for the sum of rather less than £12,000, exclusive of fittings. The warming arrangements are by Mr. D. O. Boyd, of Maddox-street, Regent-street.

The clerk of works is Mr. W. H. Williams. The material is red Woolpit bricks, made of a special size, to work four courses to 9in. The stone is Douling, with Ancaster stone for the tracery and finer work. The building was commenced in May, 1877, and is now nearly completed.

BRIDGE AT UNDERLEY PARK, WESTMORLAND.

THE accompanying view represents the bridge recently built over the river Lune, at Underley, in the Luncedale, the seat of Earl Beattie, M.P., being part of other extensive improvements on this estate. The bridge is built of light-coloured freestone from Docker Moor, some portions in red stone from Fearth. It has two segmental arches of 70ft. span, and rise of 13ft. 6in., and a land arch of smaller size. The arch soffits are formed of bold ribs, somewhat in the style of the ancient bridge at Kirkby Lonsdale. The wide span of the arches was almost necessitated to avoid the building of piers in the river, the bed being merely shifting and loose gravel to a great depth; indeed, the building of the single pier in centre and land pier proved a work of great risk and expense, the dams and piling being frequently carried away by the floods. The elements were most unpropitious throughout, the river frequently rising 14ft. or 15ft. in a day. The work was carried out principally by Earl Beattie's workmen, under the direction of Mr. P. Leitch, clerk of works, and Mr. Crittenden; the centreing by Mr. Geo. Bush, of Preston. The architects are Messrs. Brade and Smales, of Kendal.

"BUILDING NEWS" DESIGNING CLUB—A COTTAGE HOSPITAL.

"TRIANGLE IN CIRCLE" is the motto adopted by the author of the design placed first in the competition among the members of our Designing Club for a cottage hospital, and we publish his drawings this week. We have already remarked upon this and the other designs, none of which can well be considered as really good examples of hospital placing, though the selected design has some suggestive points both in the plan and elevations.

PUBLIC WORKS IN FRANCE.

FRANCE, though she has her share in the general stagnation of trade, is occupied with gigantic projects for public improvements. M. de Freycinet, the Minister of Public Works, has outlined a scheme of railway, canal, and harbour extension, for 1879, which will cost the enormous sum of £16,000,000,000, and will probably have legislative sanction for it in its entirety. One of the main features of the plan, and that which will consume the greater part of the vast appropriation, is the extension of the railroad system of France. The rest of the money will mainly go to the construction of new harbours and the improvement of the old ones. Another great public work which is urgently demanded by several of the departments is a canal from Creil-sur-Oise to Beauvais, Amiens, and Albert, with two important branches. It is averred that this extensive canal would be of the greatest value to the north of France; and it would certainly be the most considerable of all navigable French waterways, and would have the effect of reducing by one half the present freight charges from English ports to Amiens, Paris, and beyond. A scheme for the construction of a network of metropolitan railways in Paris was hardly perfected before M. de Freycinet stepped in and claimed the perfected lines as belonging to the category of lines of general interest. Their concession has therefore been transferred from the Municipal Council to the general government. The cost of their construction is estimated at nearly a million dollars a mile. The Minister of Public Works has also obtained the appointment of a supreme commission on the treatment and utilisation of French rivers, composed in equal thirds of legislators, officials, and manufacturers or agriculturists. It will consider irrigation, motive power, inundation, water supply, sewage, and similar questions. Add to all this his vast project of harbour improvement, and we see that M. de Freycinet has laid out a scheme of public works for France which will occupy the Republic for many years to come, constituting a system of internal improvements of extraordinary magnitude, which, if it is successfully completed, will itself make the new Republic memorable for generations.

THE SOUTH TRANSEPT OF YORK CATHEDRAL.

AS this beautiful portion of the noble cathedral of the northern archiepiscopate is occupying our attention, having for some years been in the hands of Mr. G. E. Street, R.A., undergoing a thorough restoration, it may not be out of place to note that the Rev. Canon Raine, of York, in compiling his "Lives of the Archbishops of York," a work of great research, gives some valuable information respecting this particular part of the cathedral. It appears to have been built by Walter de Gray, archbishop 1216 to 1255, a scion of a family which in many branches has accumulated both wealth and honour, one that has given great men to England and is still represented on the roll of Peers. Of the many scenes enacted in the time of this martyr bishop, that of his attendance upon King John at Runnymede in connection with the signing of Magna Charta is conspicuous, as is the influence he lent towards the passing of the "Charta de Jurista." In connection with the high offices he held it may be noted he was at one time Lord Chancellor, and at another the Regent of the Kingdom during the king's absence at the wars in France. One of his acts was the purchasing of a large property in London, whereon he erected a palace for the northern primates. This was known until Wolsey's time as "York Place," from which time it was called Whitehall. As the work of this great primate the beautiful west front of Ripon Cathedral may be mentioned. With regard to York Cathedral, our author says: "Gray's noblest work was the erection of the south transept, in which he was interred. It is the choicest portion of that glorious temple, and the Early English style of architecture may there be seen in the supremacy of its beauty. In boldness of arrangement and design, and in richness of decoration, the south transept is without a peer. How many of those who gaze with curious and admiring eyes upon arcade and carving, are ignorant of the piety and merits—nay, of the very name—of the prelate who called them into being more than six centuries ago?"

As to the exact date of the erection of this beautiful work, Canon Raine says:—"From the fact that Gray granted an indulgence for the church of York in 1227, and that several other gifts were made about the same time, it may reasonably be inferred that the building of the transepts was then going on. That on the south side must have been completed before 1241, the year in which Gray founded his chantry at the altar of St. Michael. The north transept, which is ascribed to John Romanus, senior, was probably built shortly before Gray's work. It is less rich, and probably, therefore, of an earlier date. Romanus became sub-dean in 1228, and died in 1256."

The altar of St. Michael here alluded to was erected in a chapel formed in one of the bays of the eastern aisle of this transept, and in this chapel Archbishop Gray was buried. Professor Willis, in his "Architectural History of York Cathedral," says:—"The pier arch under which the tomb stands is made wider than the others, apparently to give it importance." This, it is assumed, was so made that the founder might rest beneath it.

This celebrated tomb, illustrations of which have been given in this journal, to use the words of Canon Raine, "is one of the most striking memorials of the age in which it was set up. The Archbishop, who seems to have been of small stature and a slight frame, is stretched out at full length, with his pastoral staff in his hand, which is thrust into the mouth of the serpent. The details of the figure and its adjuncts are full of simple elegance. Above the sleeping prelate, on ten light and graceful pillars, there towers a magnificent canopy, which terminates in finials of the most beautiful design. Many will be surprised to learn that these are of modern workmanship, and that they were moulded less than a century ago by an Italian of the name of Bernasconi, a sculptor of great merit. I cannot bestow too high praise on what he has done, for he seems to have been imbued with the true spirit of Christian art. He has crowned each finial with two thrushes in full song, wrought with exquisite skill, and resting upon woolpacks. These finials are, it may be noted, of plaster." In "Drake's Eboracum" (427) there is an engraving of the tomb before Bernasconi meddled with it; and this author mentions a curious story which was believed in

his day, that the Archbishop had died under a sentence of excommunication, and that his body, therefore, was not laid in sacred earth, but in the canopy over the pillars. The too curious antiquary made an incision into the stonework, and soon found that there was no hollow within.

HOSPITAL PLANNING.

IN a recent number of the *American Architect and Building News*, Mr. M. Carey Lea, of Philadelphia, comments on the present systems of hospital planning, and offers a plan, which is annexed, wherein he has endeavoured to attack the difficulties of hospital construction in a new manner. The building has a somewhat triangular shape, and the wards all face either south-east or south-west, so that they all receive ample sunlight, and in summer get all the breeze that is to be had. The principal staircase is marked S. In the space marked A are intended to be placed the baths and water-closets on each story; also the store-rooms. In the space B is placed, on the ground-floor, the kitchen; on the second floor, the apothecary's shop; on the third floor, the operating-room, for which, with its north light and sky-light, it

is particularly well adapted. "I am aware," says Mr. Lea, "that those architects whose main object it is to produce a showy building will object to the fact that the face on which the main staircase opens is not terminated by right angles. If this objection is insisted upon, it can be met by sacrificing a ward in the centre of one of the square sides, and treating that side as the main front of the building. I have preferred, however, to draw the plan in the manner that gives the greatest possible advantage to the interior. Inspection will show that excellent ventilation is obtained by the halls, which cross each other at right angles; so that in whatever direction the wind may come, these halls, opening south-east, north, and south-west, must carry air through the whole building. The triangular spaces on each side of the main staircase, the shape of which would be objectionable for wards, are perfectly well adapted for the uses assigned to them."

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE annual general meeting of the Institute was held on Monday evening, Mr. Charles Barry, F.S.A., President, in the chair. The secretary read a letter from Mr. S. W. Kershaw, M.A., stating that in consequence of the increase of his duties at Lambeth Palace Library, he felt it necessary to tender his resignation as librarian of the Institute, an office he had held for eleven years, and which he relinquished with great regret. Mr. Octavius Harsard proposed a vote of thanks to Mr. Kershaw for his lengthened and valuable services, and referred to his assistance in the enlargement and rearrangement of the library. The motion was seconded by Mr. Joseph Clarke, and supported by Mr. Wyatt Papworth and Professor Donaldson, the last-named speaker observing that Mr. Kershaw, though not an architect, had largely acquainted himself with architectural literature, and had discharged his duties at the Institute in an admirable manner. Mr. Kershaw briefly responded, acknowledging the compliment paid him.

In reference to the forthcoming International Exhibitions to be held at Sydney and Melbourne, the PRESIDENT read a letter from the Prince of Wales, dated April 21st, in which His Royal Highness, as President of the Royal Commission for the Australian Exhibitions, requested the members to lend their assistance in promoting the success of these exhibitions, and asked the President of the Institute to bring under their notice as soon as possible the desirability of securing such an exhibition of drawings as will

maintain the reputation of British Art at these exhibitions, where the artists of Italy, France, Germany, and Belgium will be well and largely represented. The exhibition at Sydney will be opened on September 1st next, and all objects intended for it should be despatched not later than the first week in June. It is proposed that at the close of the Exhibition in Sydney, the drawings should be transmitted to Melbourne for the Exhibition which is to be held therein the following year. The PRESIDENT said that as only three or four weeks remained in which to prepare for this exhibition, it was hardly practicable to appoint an executive committee; the council would, therefore, exercise their functions in this matter. The machinery which was in use for the Paris Exhibition would still be available; the drawings intended for the Paris Exhibitions could be received at South Kensington as before; that the Commissioners of the New South Wales Government undertook the cost of collecting, and packing in cases lined with zinc, the exhibits; while the Commissioners appointed in London would effect insurances to cover all risks from the time the pictures were obtained till the time they were returned. It was further proposed that the drawings, after they had been exhibited at Sydney, should be sent on to Melbourne under arrangements of precisely the same character. In a conversation which he had on the subject with the Prince of Wales the other day, His Royal Highness intimated that the architectural works sent to Paris, together with others that might be produced, would in his opinion be suitable for exhibition in Australia—for as very few Australians were able to go to Paris, they would be new to them, and might satisfactorily be exhibited as illustrations of British art.

The PRESIDENT read a special report, prepared by the Council, as to the Premises Improvement Scheme. It recounted the proceedings taken by them, the appointment of Mr. C. J. Phipps as paid architect, and the various plans made by that gentleman in order to meet the requirements of the members, especially in the matters of improved lighting, ventilation, and access to the meeting-room, increased library accommodation both for books and readers, better office, tea-room, and lavatory arrangements. The plans were considered more expensive than could be warranted by the present financial resources of the Institute, and it was deemed necessary to confine the operations to such improvements as the premises at present occupied by the Institute are capable of within themselves. The Council, therefore, were prepared to recommend as follows:—1st. To retain the present meeting-room, but to obtain better daylight by greatly enlarging the windows; better ventilation to it, for evening meetings, by the construction of an efficient extracting shaft; and to alter the seats, and provide tables, &c., so as to afford good accommodation for readers at all times, except during the twelve or fifteen nights a year when it is used for sessional meetings, when the benches could readily and quickly be arranged for that purpose. 2nd. To construct a broad new staircase without winders, and secure a private entrance to the Institute rooms, so as to make them self-contained. 3rd. To form a separate outer office for clerks, instead of the Council-room being the only room for the secretary and the clerks, as is now the case,—an arrangement obviously of the greatest inconvenience. 4th. To obtain better and larger lavatory accommodation. 5th. To obtain for the nights of meeting a more commodious tea-room and cloak-room. Plans were submitted to the meeting embracing these objects, and which, it was estimated, might be executed for about £1,200; while a further £800 would suffice for the new and increased fittings, extra furniture, &c., or a total of £2,000. The Council had therefore negotiated (subject to the approval of the general body) a new lease for 79 years from the Architectural Union Company at an increased rental of £100 a year.

After some discussion, Mr. EDWARD T'ANSON suggested that the meeting should express an opinion as to the desirability of carrying out the large or the small scheme sketched in the report read by the President, and it was resolved:—"That it is not at present expedient to appropriate the upper rooms of the building (9, Conduit-street, W.), but that it be referred back to the Council to re-arrange the entrance, the staircase, and the first-floor rooms in the best manner which can be devised, and to carry the same into effect."

The Hon. SECRETARY called attention to the inexpediency of binding the Council not to take any portion of the upper floors with a view to improving the ventilation of the meeting-room, and it was ultimately resolved:—"That the Council be not restricted to avoid any interference with the upper floors, but that, if an additional area can be there obtained of moderate extent, they have power to negotiate for the same with a view to improve the ventilation, and make the required arrangements relating thereto with the Architectural Union Company; and further, that the Council be empowered to surrender the present lease of the premises, and to make the necessary arrangements for executing a new lease with the Architectural Union Company."

The Report of the Council for the official year, 1878-79, having, according to precedent, been taken as read, was received, and along discussion followed in which Messrs. C. F. Hayward, T. Blashill, C. H. Cooke, G. E. Street, Joseph Clarke, W. Papworth, and C. L. Eastlake took part. The Report, 1879, and the Balance-Sheets, 1878, were then adopted.

The following gentlemen were elected to the offices of President, Vice-Presidents, Secretaries, and other Members of Council, for the year terminating on the first Monday in May, 1880:—President, John Whicheard, F.S.A.; Vice-Presidents, Thomas Hayter Lewis, F.S.A.; Horace Jones, and Edward Middleton Barry, R.A.; John Macvicar Anderson, Arthur William Blomfield, M.A., David Brandon, F.S.A., Arthur Cates, Ewan Christian, Joseph Clarke, F.S.A., Henry Currey, John Gibson, Octavius Hansard, John Honeyman (Glasgow), Edward T'Anson, F.G.S., John Loughborough Pearson, A.R.A., F.S.A., George Vulliamy, Alfred Waterhouse, A.R.A., and Thomas Worthington (Manchester); Honorary Secretary, Thomas Henry Wyatt, F.S.A.; Secretary, William Henry White. The above form the Council. Sir Walter Rockliffe Parquhar, Bart, was re-elected Treasurer, M. Frederic Ouvry, as Solicitor, and Messrs. W. A. Boulnois and F. T. Dollman, were elected Auditors.

The following gentlemen were elected to serve on the Board of Examiners (appointed under the Metropolitan Building Act, 18 and 19 Vict., c. 122, s. xxxiii.) for the year of office 1879-80: George Aitchison, Francis Chambers, Charles Fowler, Charles Forster Hayward, Edward T'Anson, Joseph Jennings, Robert Kerr, James Thomas Knowles, Joseph Douglass Mathews, Henry Parsons, Frederick William Porter, Thomas Roger Smith, Sancton Wood. Votes of thanks were passed to the retiring president, and to the council, the treasurer, the solicitor, and outgoing auditors (who were re-elected), for their services during the past three years.

A special general meeting was held at the close of the annual meeting, Mr. C. Barry, Past President, in the chair, when the By-law (4) referring to the Declaration required to be signed by an Honorary Associate was amended, thus:—"Honorary Associates shall be persons, *not following the profession of an architect, but interested in the study of architecture, who, by their connection with art or science, are qualified to concur with architects in the advancement of professional knowledge, and who are unconnected with any branch of building as a trade or business.*"

THE ANTIQUITY OF ENGINEERING.

IN a paper read recently before the Engineers' Club of Philadelphia, Mr. George Barnham, jun., remarked that modern research has developed the fact that nearly all the materials (in a very wide sense of the word) of modern civilisation originated in antiquity; the peculiar province of our time being to ring the changes of variety upon these elements and give them an immense diffusion. The ancients originated nearly all the typical forms we now employ. They were acquainted with the constructive uses of wood; carried stone construction to a point that we have never since reached, and probably never shall; their brick-work dates from the very earliest times, and they constructed canals and aqueducts for irrigation, water supply, and inland navigation, as well as elaborate drainage systems, long before their civilisation culminated. The Chaldean structures dating from 2290 to 1500 B.C., were built of small sun-dried bricks, laid in bitumen, and faced with kiln-dried bricks

stamped with the name of the king. These temples were built on elevated platforms of beaten clay, in some instances eased with massive walls of stone, the object being to raise them above the level of the plain for architectural effect and to avoid inundation. A brick burial-vault at Mugher exhibits a rudimentary arch. The vault is 7ft. long, 5ft. high, and 3ft. 7in. wide. The sides slope gently outward until the springing line is reached, when the successive courses are pushed towards each other until they meet at the top. Similar arches are found in early Greek work at Phigalea, Messene, and other places.

The old notion that the round arch was of Roman and the pointed arch of Gothic origin has been dissipated by the spade of the archaeologist. Both of these varieties were found in Assyrian work. They are usually of brick, and occur in underground construction, as drains and vaults. The brick arch existed in Egypt as early as 1540 B.C., and a stone arch has been found dating from 600 B.C.

The masonry of the past is, of course, identical with ours, since we have simply adopted the methods of the ancients. We find in Egypt and Western Asia smooth and rock-faced ashlar, rubble, and irregular range work, essentially like that of to-day. The Assyrian and Egyptian bas-reliefs indicate their methods of moving heavy masses. Sledges were used, drawn by large bodies of men. Rollers were placed under the sledge, and the piece was carefully "guyed" by parties of men with appropriate ropes and props. The Roman military roads crossed mountains and valleys without regard to the nature of the ground; tunnels, open cuts, embankments, and bridges frequently occurring. Place cross-ties and steel rails upon a Roman road, and suppose the grade not too steep, and the points of approach and divergence of modern and ancient engineering are at once apparent. Substantially the substructure was the same as that of a modern railroad; but in place of the pedestrian or the ox-team we have the locomotive, with its "fast express" or heavily-laden freight train.

THE YORKSHIRE FINE ART AND INDUSTRIAL EXHIBITION.

THE Yorkshire Fine Art and Industrial Exhibition was formally opened on Wednesday, at York. The plans and specifications of the building have been prepared by Mr. E. Taylor (the architect of the Exhibition Building of 1866), and the foundation-stone was laid on the 22nd April, 1878. The building consists of two portions; the first a stone and brick erection, containing on the ground floor a spacious vestibule opening into a central lecture or concert hall, 98ft. by 38ft. On either side of this hall there is a suite of rooms specially arranged for the exhibition of works of art, being lighted from the roof. This double suite of rooms gives about 200ft. by 30ft. available for hanging paintings, &c. Ascending a wide staircase of stone the principal picture gallery (which is over the vestibule, &c.) is reached. This is a noble room of 100ft. long by 30ft. wide, and is at the present moment filled by the finest collection of paintings that has been seen in York. It is hoped that in this gallery there may ultimately be placed a permanent collection of works of art, the property of the city, which shall give to the Yorkshire art student some of the advantages of the Metropolitan. The Great Hall.—This is 200ft. long and 90ft. wide, having galleries running down each side 20ft. wide. In the gallery at the extreme end, and above the spacious orchestra, is the organ purchased by the committee. The floor of the great hall and its galleries are filled with a display of manufactured goods, embracing almost all departments of trade, the exhibits in the furniture and furnishing departments being specially important. To the west of the great hall is the machinery annex, covering an area of about 25,000 square feet, and glazed by Mr. T. W. Helliwell, of Brighouse, with about 11,000ft. of his patent system of roofing. In this many very interesting manufactures and processes are going forward, the motive power being a powerful steam-engine, and one of Crossley's "Otto" gas-engines. Adjoining the great hall on the eastern side is a spacious lecture-room, where from time to time exhibitions of views by the lime light and the chromatic fountain will

take place. The total cost of the building will exceed £24,000.

COMPETITIONS.

IPSWICH.—Mr. Charles Barry has been requested to report upon the twenty-two plans submitted in competition for the new post-office and public buildings at Ipswich.

PARLIAMENTARY NOTES.

LEADENHALL-MARKET AND IMPROVEMENT BILL.—The Select Committee appointed by the House of Commons to inquire into the merits of this Bill assembled for the first time on Tuesday; Lord Henry Lennox in the chair, the other members of the committee being Mr. Dundas, Mr. Cotes, and Mr. Fremantle.—Mr. O'Hara, who appeared with Sir Edmund Beckett, Q.C., and Mr. Digby, opened the case for the promoters of the Bill in the absence of his leader. He pointed out that the Bill was for the abolition of the present Leadenhall-market, for the improvement of its site and neighbourhood, for the formation of new streets, and for the establishment of a new market. The market was one of great antiquity, having been always the property of the Corporation, and had been under the control of the Markets Committee of the Corporation. He pointed out that in 1871 an Act was passed which empowered the Corporation to enlarge the poultry market, but for several reasons it was desirable that that Act should now be repealed in favour of the present Bill. The proposal of the Corporation now was to make a new market, which should give a space considerably larger than the present market, and which should be a great improvement, from a sanitary point of view, upon some part of the site which it was proposed to take, although they did not wish to be tied down as to the exact mode in which the market should be built. The market expenses would be paid by the Corporation out of their own revenue, and for that they did not require the consent of Parliament. Mr. Shaw, Chairman of the City Lands Committee of the Corporation, was examined in support of the project. The Committee adjourned.

LONDON-BRIDGE BILL.—The Select Committee of the House of Commons appointed to inquire into the merits of this Bill, for the widening of London-bridge and its approaches, assembled on Tuesday, Lord Henry Lennox in the chair; but upon the Bill being called on there was no appearance, and it was understood that the opposition to the Bill in its present stage had been withdrawn. It will, therefore, come before Mr. Raikes, Chairman of Ways and Means, as an unopposed measure.

ARTISANS' DWELLINGS ACT (1868) EXTENSION BILL.—Mr. McCallagh Torrens on Wednesday moved the second reading of the Artisans' Dwellings Act (1868) Extension Bill. Its object is to amend that Act, mainly by restoring to it the compensation clauses, the omission of which by the Lords has made it entirely inoperative. Mr. Isaacs, who had given notice of his intention to move the rejection of the Bill, withdrew his amendment on the understanding that amendments would be introduced in Committee, and Sir H. Selwin-Ibbetson signified that the Government would assent to the second reading, though they were of opinion that the clauses would require careful consideration in committee. Sir M. Ridley said the Home Secretary heartily approved the Bill, and wished it to be known that within three years all the sites cleared in the metropolis would be covered by artisans' dwellings. Mr. Goldney, Sir J. M. Gaskell-Hogg, Sir S. Waterlow, and Mr. Marten spoke in favour of the Bill. Mr. Bruen approved its extension to Ireland, and Sir J. Kay-Shuttleworth expressed a hope that something in this direction would be speedily done for the small towns and rural districts, and the Bill was read a second time.

The Church of St. Peter, Great Totham, near Maldon, Essex, was reopened on Thursday, the 1st instant, after restoration at a cost of £2,000. Among the special features beyond repairs may be noted a new pulpit of open oak on stone base, chancel fittings in oak, and new font. In the chancel a south window has been filled by a figure of St. Peter in stained glass. The two cracked bells in the tower have been replaced by a peal of six new ones, cast by Messrs. Warner and Sons at a cost of £300.

Building Intelligence.

BAWBURGH, NORFOLK.—The restoration of this parish church has been partially carried out from the designs of Mr. Ewan Christian. A new open-timber roof of Memel fir, covered with Staffordshire tiles, and with a stone-crested ridge, has been placed over the chancel, and a new stone coping and cross added to east gable; all the stonework repaired. The internal face to the chancel walls has been stuccoed, and the floor has been laid with Minton's encaustic tiles; a new door and carved benches, all in oak, erected. One of the small windows on south side has been glazed with painted quarries; the other three windows and the large one at east end have been filled with tinted cathedral glass. The porch has been re-roofed with stained open timber and repaired. The much dilapidated floor of the nave has been taken up, the surface concreted and relaid, and the monumental slabs and brasses replaced. The contractors were Messrs. Cornish and Gayner, of North Walsham.

BELFAST.—The new buildings for the General Assembly's College at Belfast are steadily progressing towards completion. They consist of a chapel, president's house, two dwelling-houses for professors, and an addition to the students' chambers. The outside walls of these buildings are being built of cut stone from the Scrabo quarries, with a moderate amount of carved work at windows and doors. As to the elevation, it has been designed to be in keeping with the present building, the main lines of string-courses and cornices of the present building being carried round the new portion. The addition to the students' chambers is at the end of the present building, to which it is similar. Accommodation for twelve additional students will thus be provided. The two houses for the professors are not being built in the college grounds, but are closely adjoining, and have all the necessary accommodation for a family. They are semi-detached, and are built with red brick, with terra-cotta and cut stone string-courses. Mr. Lanyon is the architect, and Messrs. John Lowry and Son the contractors. The buildings, which will cost about £10,000, will be completed about the end of the present year.

BIRMINGHAM.—The ornamentation of the new Council Chamber has been completed by the erection of a Riga oak screen in the recess at the back of the Mayor's chair. The screen is in five panelled compartments, divided by coupled pilasters, having richly carved floriated capitals. Each compartment is subdivided into a series of nine panels, with the exception of the centre, which has only one panel, and has on each side circular columns. The panels are filled with Italian walnut, carved in fruit and flowers, with birds and snakes. The centre compartment, projecting 3ft., forms a sort of canopy for the Mayor's chair, and upon the panel are carved an hourglass, surmounted by the motto, "Tempus fugit." The pilasters support a cove filled with green stamped leather, and having ornamental brackets carrying the projecting gallery front, the pilasters of which correspond with those of the screen. The central portion is raised and is circular in form, the arms of the borough being set in a laurel wreath of Italian walnut. In the centre the screen is 17ft. high, and the width is 26ft. The Italian walnut used for the carved panel is cut from the largest log which has ever been imported, and was brought to this country twenty-five years ago. The wood is very hard, and the carving is well executed. The makers are Messrs. Collier and Plucknett, of Warwick, who also furnished the Council Chamber, the designs being supplied by the architect of the building, Mr. Yeoville Thomason.

CHELSEA.—St. Mary's Roman Catholic Church, Cadogan-street, Chelsea, was opened on Thursday week. Externally of a plain character, in the Early English style, the new church consists of a nave and aisles, chancels, three side chapels, a porch, and baptistry. It has a great western doorway over which are four lofty lancet windows of equal length, giving the principal light to the church; but the ordinary entrance will be from a side doorway on the north side, opening into a spacious porch taken off from the aisle. Opposite this porch is the baptistry, a distinct gabled erection at one end of the south aisle and opening into the church by a double archway. The interior of the church is 115ft.

long by 57ft. wide; the nave is 82ft. by 27ft., the chancel 35ft. by 21ft., and the aisles 15ft. wide. The roof is a plain wooden barrel vault of cream tint, slightly painted, relieved by moulded ribs (or principals) and rafters painted of a bluish green. The chancel roof is varied by being composed of a series of eaves, the springing ones being stilted. The church is built of white stocks, with stone dressings, while Hopton Wood and Corsham Down stone has been used in the interior, and the chancel is completely faced with ashlar of this material. The architect is Mr. J. F. Bentley, of John-street, Adelphi, and the works have been carried out by Messrs. Braid; Mr. Spooner being the clerk of the works under the architect. The important frontage of church, convent of Our Lady of Mercy, house for Christian Brothers, and extensive school for boys and girls, with the almshouses, occupy a space of 350ft., and are nearly opposite the mansions now being erected on the Hans Estate. We fully described the church, which is undoubtedly one of the most successful erections of its kind, in the BUILDING NEWS of Feb. 14, p. 168.

CITY OF LONDON.—The Church of St. Katharine Cree was reopened on Sunday, after internal restoration, carried out at a cost of £3,500. The pews have been cut down from the old "omnibus" form into low, open benches. A large unsightly partition has been removed from the western entrance, giving additional space within the church. The old windows have been taken out, with the exception of a memorial one above the Communion-table and one in the south-eastern clerestory, and have been replaced by others of simple pattern in double-glazed to exclude noise. The stove, with its huge chimneys, which disfigured the south-western windows, has been disestablished, the warming being now effected by a modern heating apparatus. The south-eastern pier has been rebuilt, and all decayed timbers cut away and replaced. The whole interior has been decorated in colour. The ceiling is in pale grey, with rings of buff colour, picked out with vermilion and gilding; in panels are the arms of the sixteen leading livery companies, emblazoned in their proper colours; the cost of this portion of the work has been defrayed by the several companies interested. The walls are of a dull chocolate tint, and the columns have been cleansed and left in the natural colour of the stone. The architect is Mr. R. P. Notley, of Gracechurch-street, E.C.; and the builder, Mr. F. T. Prebble, of Camberwell.

DONNINGTON.—The parish church of Donnington, near Altringham, was reopened on Tuesday week, after partial restoration, under the direction of Mr. Norton, Mr. Martin, of Hereford, being the builder. The work was begun in June, 1878, but some delay was caused by its being decided to substitute local grey and red stone for Bath stone in the work. As the work progressed it was found that the roof of the nave was in such a bad state of repair that its removal had to be added to the work begun. The crowning difficulty which the rector and the restoration committee had to contend with was the fall, or rather total collapse, of the tower, which took place on the 25th March last. The tower had been an anxiety all along, being considerably out of perpendicular before the work of restoration was begun, iron cramps having been used to hold it together for many years past. When the west wall of the church, which was also the east wall of the tower, came to be overhauled in the course of the work, it was found to consist of rubble, and to be in a very dilapidated state, requiring to be rebuilt, the top of the tower having to be propped up. On the 25th of March a new lancet window was about to be put in on the south side of the tower, when, without any warning, except a few showers of sand and rubble, it collapsed, and lay a heap of ruins, with its roof of wood and felt lying on the top—a shapeless mass of sand, rubble, and small stones, the larger stones belonging to the upper part. The lower part of the tower was evidently weak and badly built, and was undoubtedly crushed by the upper part.

EARLEY.—St. Bartholomew's Church, Earley, was consecrated on Wednesday week. It has been erected from the designs of Mr. Waterhouse, A.R.A., by Messrs. Stephens and Baston, builders, Bristol; Mr. F. W. Barr being clerk of the works, and Mr. W. Young foreman. The church as at present built consists of nave and north and south aisles, and will seat 600 persons. The materials used are red and grey brick,

with open roof and other timbers of unvarnished pitch-pine. The columns of the arches separating the nave from the aisles are of granite, with Douling stone capitals and bases. The total cost of the church as now built is £3,600, including extras; but to really complete the building, a chancel, porch, and vestry will be needed, at an estimated outlay of £3,000.

GUILDFORD.—A series of women's almshouses is being erected next the county hospital at Guildford, from the designs of Messrs. Ernest George and Peto. They will form a quaint group of twelve houses around three sides of a quadrangle, in the centre of which will be a sun-dial. Each house will consist of a living-room with bay window, and recessed chimney-corner with settle, and small window, and also a bedroom and scullery, and an external porch, all being on the ground-floor level. The buildings are of red brick, with tile roofs, wooden cornices, and white window-frames. The charity was founded in the Curtain-road in the City of London, but Lord Onslow has given the present site in Guildford, and the old one has been sold for warehouses, thus increasing the funds of the charity. The contractors are Messrs. Goddard and Sons, of Farnham.

HANDSWORTH WOODHOUSE.—A new chapel at this place was opened last week. The external length of the building is 61ft., the width 44ft. The chapel is capable of holding 560 persons on the ground-floor and the gallery, which extends all round the building. The design is Italian. The amount of the contract for the building was £2,600, exclusive of lighting and warming. Mr. Robert Hardecastle, of Woodhouse, is the contractor, and Mr. G. B. Ford, of Burslem, the architect.

HOCKERILL.—The church of All Saints, Hockerill, near Bishop Stortford, was reopened on Wednesday week, after having undergone enlargement and improvement from the designs of Mr. Joseph Clarke, F.S.A., the diocesan architect, at a cost of £6,000. We illustrated Mr. Clarke's designs for enlargement in the BUILDING NEWS of March 1st, 1878. To the church, which was built in 1851, a north aisle has been added, opening by an arcade into the nave; the nave and existing south aisle have been prolonged westwards, and the south porch rebuilt and enlarged. The chancel has been enlarged and remodelled, and an organ-chamber, and choir and clergy vestries added. The bells are now hung in a substantial cote at the north-east end of the nave. The same facing of rag stone has been used for the new as for the old work, but the harder Aneaster stone is used instead of Caen stone; internally, with the exception of the bases, shafts, and caps of the columns, Coombe Down stone is used. The roofs are of pitch-pine, neither stained nor varnished, and the seats throughout of oak, solid in construction. The chancel floor has been slightly raised and laid with Godwin's encaustic tiles. The shafts of the east window and chancel arch are of picked Devon marbles. The contractor was Mr. Gregory, of Clapham Junction, S.W., his foreman being Mr. W. J. Crook. Mr. J. White acted as clerk of works. The windows, several of which were originally filled with stained glass, by Messrs. O'Connor, of London, have been rearranged and altered by their successor, Mr. Taylor, of Berners-street, W. The church has been warmed with hot-water by Messrs. Price and Son, of Adam-street, Adelphi.

NOTTINGHAM.—New baths in Gedling-street have just been opened by the corporation. The building measures 123ft. by 60ft., and contains a bath proper 102ft. by 44ft., with semicircular ends, and when filled to the proper height the bath contains 130,000 galls. of water. The roof is in one span of 60ft., and is carried by seven wrought-iron ribs, semicircular in shape. The soffits of the ribs are 29ft. above the coping of bath, and the total length of rib, including part below floor level, is about 95ft. Each rib for a height of 9ft. above floor level is of cast iron, the remainder is of wrought-iron with open lattice-work. The weight of each rib is about 5½ tons. The building is ventilated by a louver nearly 2ft. wide, running the whole length of the roof, the top being entirely glazed. Dressing-rooms, thirty-eight in number, and a jumping stage have been provided, and the woodwork of which these are made, as well as underside of the woodwork of roof, is stained and varnished. The cost of the work has been about £2,500. The new building and roof have been designed and con-

structed by Mr. M. Ogle Tarbotton, engineer-in-chief to the Nottingham Corporation, and the work has been carried out under the immediate superintendence of Mr. A. Brown, assistant engineer. Mr. R. Middleton was the contractor for the general builder's work, and Messrs. Goddard and Massey for the ironwork. Mr. Carr acted as clerk of works.

METROPOLITAN BOARD OF WORKS.—On Friday at this board, the works committee were authorised to act with regard to Mr. Torrens's Artisans' Dwellings Act, 1868, Extension Bill, when its clauses are discussed in committee, as they see fit without opposing the Bill as a whole. Regulations prepared under the 12th Section of the Metropolis Management and Building Acts Amendment Act, 1875, with respect to new theatres and music-halls for protection from fire, were approved by the board. It was decided after much discussion to appoint four additional inspectors to carry out the Slaughterhouses Act, Explosives Act, the Dairies, Cow-sheds, and Milk-shop's Order 1879, at a salary of £150 a year, and the sanitary committee to receive the applications and select twelve candidates, from whom the board will elect four. £390 was voted towards a proposed improvement in Cursitor-street and Took's-court, Holborn. The solicitor reported that the agreement for the acquisition and freeing from toll of Chelsea-bridge, under the Toll Bridges Abolition Act, 1877, had been sealed as between the board and Her Majesty's Office of Works.

PENOE, S.E.—A new vestry hall for the hamlet of Penoe, erected opposite the Anerley railway station, was opened on Wednesday week. The building is faced with white gault bricks with covered stone dressings, the roof being covered with Bangor slates. A clock-turret of wood covered with zinc occupies the centre of the front, and contains a clock by Messrs. Smith, of Clerkenwell. The vestry hall itself is 57ft. long by 27ft., and has two entrances. The roof is in one span, and is ceiled in panels of pitch-pine, stained and varnished, the lower beams and moulded lines being picked out in colours. Stencilling has been applied to the architraves of windows, the walls being plastered. The hall is lighted by large twelve-light mullioned windows in front and rear, and four four-light windows at the east end, glazed with white quarry-rolled plate-glass. The dais is portable. On the ground floor are rate collector's and overseer's offices and lavatories, and on the first-floor a committee room, 21ft. by 16ft. 6in. The hall, corridors, and staircase are heated upon Gundry's system of hot air. A separate house, containing four rooms for a caretaker, adjoins the offices. The architects were Messrs. George Elkington and Sons, of Cannon-street, E.C., and the builders Messrs. J. and C. Bowyer, of Upper Norwood, who took the contract at £4,341. The gas fittings were specially designed in decorated brass, and have been executed by Messrs. Strode and Co.

RHYL.—New buildings for Mr. R. Oldfield have been erected at Rhyll, designed with the idea of breaking through the monotony of the present street architecture of Rhyll, which consists chiefly of the ordinary stuccoed fronts that are so well known at many of our favourite watering-places. The works, which are now almost completed, have been carried out from the designs and under the superintendence of Mr. O. Edwards, of Rhyll, and Mr. Wm. Owen, of Manchester. The buildings are faced throughout with 2in. red bricks. The works have been carried out by Mr. J. Rhydwen Jones, contractor, Rhyll, and the total cost is under £4,000.

Two of the vacant niches on the south side of Exeter College Chapel, Oxford, which was erected twenty years ago, from the designs of Sir Gilbert Scott, have just been filled with figures of St. James the Great with staff, and St. Philip with his sceptre. The figures are each 6ft. 9in. in height, and were executed by Messrs. Farmer & Brindley, of Westminster Bridge-road, S.E. One was the gift of an old member of the College, the Rev. Mackenzie E. C. Walcott, B.D., F.S.A., precentor and prebendary of Clithere Cathedral; the other by a subscription amongst the members. The work has been carried out by Messrs. Simms and Co., of Oxford.

At Maas, County Kildare, a large block of buildings for married men's quarters are being constructed at the barracks. The contractors are Messrs. Jones and John, of Pembroke Dock.

More than Fifty Thousand Replies and letters on subjects of Universal Interest have appeared during the last ten years in the **ENGLISH MECHANIC AND WORLD OF SCIENCE**, most of them from the pens of the leading Scientific and Technical Authorities of the day. Thousands of original articles and scientific papers, and countless receipts and wrinkles embracing almost every subject on which it is possible to desire information have also appeared during the same period. The earliest and most accurate information respecting all new scientific discoveries and mechanical inventions is to be found in its pages, and its large circulation render its the best medium for all advertisers who wish their announcements to be brought under the notice of manufacturers, mechanics, scientific workers, and amateurs. Price Two-pence, of all booksellers and news-vendors. Post free 2d. Office: 31, Tavistock-street, Covent-garden W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 6s.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 33s. 30c.). To India (via Southampton), £1 6s. 6d. To any of the Australian Colonies New Zealand, the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

N.B.—American and Belgian subscribers are requested to remit their subscriptions by International P.O.O., and to advise the publisher of the date and amount of their remittance. If the last-mentioned precaution is omitted some difficulty is very likely to arise in obtaining the amount. Back numbers can only be sent at the rate of 7d. each, the postage charged being 3d. per copy. All foreign subscriptions, unaccompanied by an additional remittance to cover the extra cost of forwarding back numbers, are commenced from the next number published after the receipt of the subscription.

Cases for binding the half-yearly volumes, 2s. each.

RECEIVED.—W. B. and Co.—G. W. Ry. Co.—W. N. R. S. A. T. A.—B. of S.—L. and N.—R. M. and Co.—B. and T.—D. and H. J. N.—W. H. L.

R. W. (We do not know the name or address of the consignee or manufacturer in this country of the Norwegian wooden houses. We have had many inquiries from time to time respecting this matter, and if they are still supplied the makers would do well to announce the fact in our advertisement columns.)—W. G. F. (Perfectly fair, but very unreasonable. No blame, however, can attach to the other architect.)—J. J. FISH. (Sketches are to hand, and shall appear as soon as space will permit.)

"BUILDING NEWS" DESIGNING CLUB.

DRAWINGS RECEIVED.—Ogmore, Molina, Try, Curiose, Honey Dew, Revus, Be to its Merits, Impavidum, Ferrient Runne, Elève, Truth shall Prevail, East Anglian, Melmotte.

LIST OF SUBJECTS.—1. A small detached stable containing 2 stalls and a loose box, with harness-room and hay-loft, coach-house and coachman's rooms. Plan, section, and elevation with sketch. Scale, one-sixth of an inch to foot. 2. A summer-house in wood for a suburban garden. Scale of drawings, half an inch to the foot.

Correspondence.

RAMSGATE PROPOSED NEW ROAD COMPETITION.

To the Editor of the BUILDING NEWS.

SIR,—The letter in your last impression on this subject was most suggestive. Let us first glance at what Johnson says as to a referee or arbitrator. The last he terms an "Extraordinary judge between party and party, chosen by their mutual consent."

"Be a good soldier or upright trustee,

An 'arbitrator' from corruption free."

DRYDEN.

Of the first he says—

"Referees and arbitrators seldom forget themselves."

SIR R. L'E STRANGE.

Now, what are we to say to this Vice-president of the Institution of Civil Engineers, the arbitrator and referee of the Ramsgate Local Board who does not "compete in 'designing'" (sic). My son applied for plans and conditions? If the extension of the L. C. and D. Railway were a *sine quâ non*, why was it not so stated to competitors by the Ramsgate authorities? In other

words, was it commonly and decently honest of them to refer some seventy plans—the authors of whom, though inclined to "compete in designing" might many of them be found to be the professional equals of the Ramsgate arbitrator, who, not competing, obtains the plans prepared for competitors surreptitiously through his little boy—to a professional man interested individually in a project never referred to or implied in any way in the instructions furnished to competitors?

From an experience far anterior to that of the arbitrator, the writer of this letter joins issue entirely with him as to the benefit to be derived from an extension of the L. C. and D. into the town. A line connected with the quays of the inner harbour might be a desideratum for foreign goods, but let the townsmen of Ramsgate study Dover "ante" and posterior to the extension of the L. C. and D., and let them take warning in time. We are told the ratepayers are not bound to either of the three plans selected except as regards premiums. Let them adhere to this. It was also stated the town authorities would exhibit, if they thought fit, the designs sent in. Let them by all means do so, giving those competitors who wish it the opportunity of showing their colours and disclosing their names. The Ramsgate public would soon arrive at a just conclusion whether the premiated drawings are the best or not. There must be great similarity in the designs confined within a groove defined by a Parliamentary plan and a confined area by dotted lines of deviation and the limit of five feet vertical divergence as regards levels. Is it wise to perpetuate the Albion Hill nuisance on a great scale by compelling connection with Harbour-street and the centre of the town? Is Ramsgate expected to extend east and west? What is wanted? Is it a coast drive and promenade, or merely a town street? If the former, should not the example of Scarborough be followed and make the last subservient to the first consideration?—I am, &c.,

ANOTHER COMPETITOR WHO PROTESTS.

CREOSOTED TIMBER.

SIR,—I have been somewhat amused by the correspondence in your paper on the above subject. A portion of the evidence given by me before a coroner's jury with reference to the failure of some timber staging which had been creosoted found its way into your paper and was headed "The danger of creosoting timber." Had the whole of my evidence been before you, doubtless the heading would have been "The danger of improperly creosoting timber." Practically there is no difference of opinion between myself and your correspondents, Messrs. Armstrong and Co. The three upright supports of the timber stage which fell were all of them more or less rotten in the interior, while externally they were perfectly sound. The timber itself was some of the finest Memel that I have ever seen, was specially selected by an eminent engineer at the time the work was executed, and was very strongly put together. My evidence, which the jury and coroner adopted, proved the following facts:—

That the creosote had only extended to about 23in. into the wood from the exterior, and that the internal parts of the posts had, in fact, for many years been practically suction tubes, the water being drawn up by capillary attraction into the interior of the posts, and rotting the heart of the timber, without any chance of the decay being detected, or the gases generated by the decay finding a vent through the strongly-creosoted external surfaces to the air.

Mr. James Newlands, late Borough Engineer to Liverpool, in his "Carpenter's Assistant," p. 106, states, "There is great difficulty in injecting creosote into the heart of wood, and into hard woods it cannot be perfectly injected." Certainly, in the present case, the creosote had never reached the heart of the timber, and hence, in my opinion, the decay to all the posts. No doubt the process has of late years been brought to a much greater degree of perfection than it was about 25 years ago, when this wood was done, for instance. I am informed it was customary to force about 5lbs. of creosote into each cubic foot of wood, but that now as much as 10lb. per cubic foot is frequently forced in.

The late Mr. Brunel used on the Great Western Railway works invariably to insist that the timber should be weighed in order to ascertain that every part of the wood had imbibed its proper quantity of creosote.

No one will dispute for a minute that porous timbers are much improved by the process, such as the fir at Capo Town, and the railway sleepers, &c., alluded to by your correspondents. I think however, reflection will convince any practical engineer, that unless the creosote thoroughly enters into the heart of the timber it is certainly unwise to use it for wooden supports standing in water.

It is well known to every sailor, that if wooden spars and posts on board ship are coated all round with black varnish the wood speedily decays, and were an upright post to be partly fixed in water, the portion above the water-line being hermetically closed all round by lead the wood would certainly quickly rot; and unless the creosoting is properly performed, the system of false circulation kept up in the heart of the timber when it stands in water, would in my opinion do more harm than good. The moral is, either make sure that the creosoting to timber piles is properly performed, or use the wood in its natural state.—I am, &c.,

ROBERT WALKER.

STREET CARRIAGEWAY PAVEMENTS.

SIR,—In your issue of the 2nd inst. you give an abstract of my paper on "Street Pavements," recently communicated to the Institution of Civil Engineers. The heading of the principal table, however, is altogether omitted, and without it the figures are scarcely intelligible, as it explains that the prices are reduced so as to apply to a standard traffic of 100,000 tons per annum for every yard of width in carriageway, while the second table applies to a standard traffic of 40,000 tons per annum for every yard of width in carriageway.

Owing to the closer printing of the portion of the paper relating to the dimensions of sets a misapprehension would readily arise, and it appears necessary to explain that the width of the sets is not 4in. to 14in., but that four sets measure 14in. in width. The heading of the tabular forms giving the dimensions of sets contains the expression, "Hard stone in which joints were unnecessary for foothold;" it should be, "Hard stone, in which joints were necessary for foothold."—I am, &c.,

GEORGE T. DEACON.

Borough Engineer's Department,
Liverpool, 5th May, 1879.

CREWKERNE GRAMMAR SCHOOL COMPETITIONS.

SIR,—It is now more than three months since the drawings were sent in for the above competition, and, so far as I know, none of the competitors have heard a word about it, nor has any acknowledgment of the receipt of the drawings appeared in either of the professional papers. Surely it is time something was made known. Can any reader throw any light on the subject? I am, &c.,

A COMPETITOR.

PROPOSED MUNICIPAL BUILDINGS, GREENOCK.

SIR,—I have sent the inclosed letter to the Provost and Town Council of Greenock, and shall be glad if you will insert it.—I am, &c.,

A COMPETITOR.

"To the Provost and Town Council of the Borough.

"Gentlemen,—Having sent in drawings for the above, permit me most respectfully to call attention to a report which has just reached me to the effect that your own harbour engineer is amongst the competitors. Whilst unwilling to believe that a gentleman holding a good salaried appointment as engineer from a board of which you are all members would attempt to compete for an architectural work of which you are to be the judges, or yourselves permit a proceeding so manifestly unfair to all the other competitors, I feel it my duty to bring to your notice what is being said on the subject, trusting it is without foundation. Should, however, such drawings have been sent in, you will at once see that any report your master of works might make as to the relative merits of the plans submitted would certainly be looked upon with suspicion from the fact of his having been so long in the office of the engineer alluded to, and consequently interested in its success. About sixty gentlemen have, I believe, shown their confidence in you by submitting at your own request, and considerable expense and trouble, drawings for your selection, and I feel sure that, as public men, you will show that it has been rightly placed by excluding all paid officials from the competition, and awarding the prize to the best plan.—Faithfully yours,

"A COMPETITOR."

Entercommunication.

QUESTIONS.

[5757].—**Lime and Portland Cement.**—It is a popular plan in Staffordshire to mix Portland cement and lime-mortar for pointing. Is it a desirable compound?—M.

[5758].—**Descending Flue.**—I wish to construct a stove or fireplace in entrance hall of villa, with descending flue passing under room floor to flue in wall, 18ft. distant from wall of hall, which is only 9in. thick. Will some reader who has done similar work give particulars, with sketch if possible as to most suitable form of stove, construction of fireplace, and flue under floor, so as to secure efficiency and safety?—W. W. W.

[5759].—**Timber Verandah.**—Whether is oak, teak, or pitch-pine the best timber for use in outside construction of verandah or porch, and what is most suitable treatment in way of varnishing, &c., for durability and beauty?—W. W. W.

[5760].—**Carrying Weight of Floor.**—What weight per superficial foot will a floor carry with timber of the following dimensions:—Beams (pitch pine), 16in. × 9in., 18ft. hollow, and 9ft. 6in. asunder; joists, 9in. × 3in., and boards, 1in. thick.—WORKMAN.

[5761].—**Built Girder.**—Would Mr. H. Ambrose or other of our kind friends inform me through your columns what would be a safe distributed load (consisting of brick-work with window openings) for a girder of the following description to carry—viz., Two rolled iron joists, 16in. × 6in. × 3in. web throughout, with top and bottom plates each in one length, 14in. × 3in., and 14in. × 3in. respectively, riveted to joists, to have a clear bearing of 31ft. Also, whether the stronger plate should be on the top or the bottom?—H. S. WARRINGTON.

[5762].—**Local Board By-Laws.**—Will you or some of your numerous readers inform me and my fellow parishioners, through your valuable paper, how to go to work to get certain restrictions contained in our Board of Health by-laws amended or rescinded? What pressure can be brought to bear upon the members of the board? What constitutes advertising them previous to their being sent to the Local Government Board for sanction?—COUNTRY BUILDER.

REPLIES.

[5752].—**Coloured Building Stone.**—The names of stones I gave, if overdone, were intended to reply to a certain question which "J. W." has overlooked. As to what are the best coloured stones for a certain locality or position is altogether another question, and is one which the architect himself must decide. What may please "J. W." in colour would probably be distasteful to another, and the obvious want of the profession is the names of stones classified as regards colour and durability. The Red Mansfield referred to is, when well selected and laid, a durable stone, and the darker varieties wear the best. St. Pancras Hotel in the Euston-road shows the employment of this stone on a large scale, and where its peculiarities can be fully tested.—G. H. G.

[5745].—**Wood Roofs.**—Thanks to Henry Ambrose for his trouble, but I fail to see the working out of his formulae. For the latter he gives the figures "295" and "294" but how does he arrive at them? If it would not be troubling him too much, would he kindly give detailed workings out for the various parts, assuming certain strains to be on those parts. Also thanks to "G. H. G.," but why such a vast difference between the sectional area given by the way he mentions, and the sectional area given by "Tredgold"? An answer would oblige, stating how the difference is made up.—NIL DESPERANDUM.

[5751].—**Board School Plans.**—It is not necessary that the quantities be sent with the specification, but a comprehensive set of plans are required, including a block plan of the site, showing drainage, &c., together with elevations and sections. These are generally sent to the education department through the clerk to the school board, and must be again sent up for final approval after the cost of carrying out such plans has been ascertained, but before any contract has been entered into.—R. C.

[5752].—**Staining and Polishing Church Seats.**—"V." can give any desired colour to his deal church seats by using Benson's stain. I have stained deal floors very successfully with it. The powder is in shilling packets, weighing something over an ounce, and making when dissolved in water, one quart of stain. It must be applied with a common brush, as it has one fault, it spoils the brush. For a light shade such as "V." wants, a packet would do about 150 square feet, I think. The dull polish must be given by rubbing with boiled linseed oil. For floors beeswax and turpentine is best, no varnish required. I bought mine at the Army and Navy Stores. There is no smell or mess in using it.—R.

[5753].—**Abutments.—Struts and Braces.**—The formula referred to by "Alt Belcher" can be worked as follows:—Say, L = 10 and p = 10, then B = 0.6 D and D = $\sqrt{L \cdot p \cdot \frac{1}{2} \times 0.8}$ (fir). Let us find D (using fir), then D = $\sqrt{10 \times 10 \times \frac{1}{2} \times 0.8}$. Find $\sqrt{10}$. Log. of 10 = 1.000,000, and divided by 2 we shall find the nearest Log. gives 3.163. ∴ D = $\sqrt{10 \times 3.163 \times 0.8} = \sqrt{3.163 \times 0.8}$ Log 3.163 = 1.500099, and 1.500099 = Log. 750099, and which gives 5.071. ∴ D = 5.071 × 8 = 4.056, say, 4in. = D = depth and B = breadth to be 0.6 D = 2.4in., and thus a strut 10ft. long in a roof truss would come out by formula quoted practically 4in. × 2½in. Can same be strong enough?—HENRY AMBROSE.

[5753].—**Abutments.**—According to formula quoted last week, and worked according to the explanation of same given in Spon's book of "Architects' Formulae," &c., or according to what may reasonably be construed to be meant by same. Take for an example an arch of brick to stand by itself and 22ft. span, and to be semi-circular, then the radius will be 16ft. Let us find D, D = $n \sqrt{R}$ = 4 × 4 = 16 = D in feet. Now, "W" = weight of one foot in length of half arch in cwt., which we shall construe to mean the average weight of a foot girt under

soffit of that part of the arch above the arch joint at or nearest to 45° of inclination with the horizon. Now, this must necessarily include any weight which may bear on that part of the arch in addition to the weight of the arch itself, and what may be permanently placed on it for the purpose of weighting it heavily in equilibrium, although a semi-circular arch, if of an equal thickness, can never be said to be even approaching a state of equilibrium, its curve being so different to the parabola, whose double ordinate would be = span and its absciss = radius; but with any arch the greater the properly distributed permanent load placed on it the less will a moving load on any point affect the then weakest part of the arch, and provided always that our load cannot crush the material of arch itself. To proceed, let us assume two tons per foot = 40cwt. as = W. "H" we shall assume to mean the height of the springing, in feet, above the solid foundation on which the abutment pier or abutment is built. "R" = radius at the crown in feet most probably contemplates the possibility of a parabolic arch, and in which R would be much less. We should have to assume a radius equal to about half the principal parameter, and when, of course, by our formula we should have less pressure built-up on the abutment and much more now being downwards as weight instead of horizontal pressure. To resume, let H be equal to 10ft., and "T" = thickness of the abutment in feet. Then

$$T = \sqrt{1.5R^2 + \frac{2}{3}R^3} + \left(\frac{W}{H}\right)^2 - \frac{W}{H}$$

$$= \left(2 \times 256 + \frac{1}{3} \times 10^3 + \left(\frac{40}{10}\right)^2\right)^{\frac{1}{2}} - \frac{40}{10}$$

To find R^{1.5} without being in an exponential form, we may here remark that exponents of evolution when expressed in a vulgar fractional form mean that the vulgar fraction of the logarithm of the number under the exponent may have to be found, and the resulting decimal fraction will be the logarithm of the number required. If the vulgar fractional exponent is an improper fraction—that is, if it is greater than unity, and if the decimal logarithm to be operated on is nearly equal to unity, it will very likely follow that the consequent multiplication will produce a logarithmic quotient also greater than unity, when the proper decimal pointing will show that which we shall have to include in the index of the number required. In multiplying it will also be necessary to cut off any decimal places we may obtain exceeding the decimal places to which our tables work, and in cutting off more than figure 5 we should make the next figure, and which we retain, greater by 1, or if it is a 9 then make it a 0 and carry one to the next place. To proceed—

$$\begin{aligned} R^{1.5} &= 16^{1.5} \\ \text{Log. } 16 &= 1.204120 \\ \text{Log. } 16^{1.5} &= 1.102660 \end{aligned}$$

2.306180 = Log. 202
∴ R^{1.5} = 202 and 202 × 2 = 404
80.8, and 256 × 1 = 256 × 2 = 51.2, and $\left(\frac{40}{10}\right)^2 = 4^2 = 16$, and $\frac{40}{10} = 4$. Hence we have T = (51.2 + 80.8 + 16)^{1/2} - 4 = (148)^{1/2} - 4. Log. of 148 = 2.170262 and $\frac{2}{10} = 0.2$
= 1.085131 = Log., say, 12.17, hence T = 12.17 - 4 = 8.17, and $\frac{17}{100}$ of a foot will be $\frac{12 \times 17}{100}$ of an inch = $\frac{204}{100}$ of an inch = 2.04 inch. Therefore the thickness of the abutment comes out according to the formula in Spon's book at 8ft. 2in. thick, and which happens to be about 4-5ths its height from foundation to springing.—HENRY AMBROSE.

[5755].—**House Details.**—The strips of lead referred to are put in with the view of preventing the damp from finding its way to the inside 4½in. work over the top of arch or lintel. They are placed over the lintel of opening and should turn up about 3 or 4in. on each side of the cavity into the joints of the brick and stone work, and as the cavity is 2½in., 10 or 12in. in width would be sufficient for the purpose.—Q.

[5755].—**House Details.**—The strips of lead should be about 4in. wide let into the outer wall above the openings and dressed over the frames. It should be turned up slightly against the inner brickwork, though not to touch it, so that if the wall let through the wet it should not touch the inner face but be carried away into the hollow. The mode I have adopted is not to let the lead touch the inside brick wall, though it is sometimes laid upon the frame and simply dressed up on each side, a plan that is ineffective in many instances. Often "coppers" are made of galvanised iron, and not copper, but which the specified article is to be will depend on the wording of specification. If a "25-gallon copper" only is mentioned the builder may plead that an iron one was all he intended. I have known several instances where a similar case of dispute has occurred, and in default of precision or qualifying meaning, the builder has the best of the contention.—G. H. G.

STAINED GLASS.

TICHMARSH.—A stained glass window, by Messrs. John Hardman and Co., has lately been erected in the south side of the chancel of Tichmarsh Church. It consists of three lights and tracery of the style of the 15th century, in accordance with two windows in the same wall, and the large east window in the chancel, all of which are the works of Messrs. John Hardman and Co. The subjects represented in the window now erected are:—In the dexter light, "Feed My Lambs"; centre light, "The Widows showing St. Peter the Coats made by Doreas"; sinister light, "St. Peter walking on the sea." The heads of the lights are filled with canopies, and the bases with angels holding scrolls containing texts, and at the extreme foot of the lights is the inscription recording the dedication of the window.

Cardigan Town Council last week adopted the plans of Mr. A. Szlumper, C.E., for the proposed new waterworks, and entered into the purchase of a site for the proposed reservoir.

WATER SUPPLY AND SANITARY MATTERS.

WATER SUPPLY AND ENTERIC FEVER.—The report of Dr. Thorne Thorne to the Local Government Board upon the results of his official inquiry into the late outbreak of enteric fever at Caterham, Redhill, and the neighbourhood has been issued. With regard to Caterham, the inspector says that the first person attacked sickened on January 19th, and up to February 2nd 47 persons were attacked. Of 558 houses in Caterham, 419 were provided with water from the mains of the Caterham Waterworks Company, and of the 47 persons attacked 45 were found to have resided in houses supplied with the Company's water, and the remaining two to have visited such houses and drunk the water. At Redhill similar circumstances were known to exist. Up to the end of February the total number of attacks reported was 303, 224 occurring in Redhill, 9 terminating fatally; and 81 at Caterham, 5 terminating fatally. At Earlwood Asylum, where the first case occurred on January 28th, 38 persons were attacked, 33 being patients and 5 servants, and here 5 fatal cases occurred. The progress of the disease in this institution seems to have been stayed by the medical superintendent, Dr. Graham, having cut off the Caterham supply of water on February 8th. Out of 622 houses in Godstone, Betchingly, and Nutfield, 96 were provided with the company's water, and at 9 fever prevailed, 6 being at Nutfield. The total number of cases to the end of February was 352, and the total of deaths 21. Dr. Thorne having so far tracked the fever to the water, next made inquiry as to whether any accidental contamination of water in the reservoirs or in the mains could have resulted from any irregularities in the supply during the recent boring operations, but circumstances led to the inquiry being extended in another direction. During the latter part of 1878 and the beginning of 1879 the Caterham Waterworks Company constructed an adit from one of their old wells up to the new bore, which was then being sunk. The adit is situated in the chalk at a depth of 45ft., it measures 6ft. by 4ft., and is 90ft. in length. A number of men were employed in this work, some of them being in the well below, others on the surface. Inquiry was made as to whether any of these ailed while at their work, and it was ascertained that one of them who left work some time in January was believed to have been ill, although no inquiries had been made concerning him since he quitted the works. This man the inspector sought out; Mr. Jacob, the medical officer of health, accompanying him. From investigation they ascertained that the man was employed as "loading man" at the new adit, and whilst at work was seized with enteric fever of a mild character which compelled him to evacuate in the adit, and the bucket used was then lifted to the surface, emptied, and used for the conveyance of materials into the adit. Dr. Thorne points out that where enteric fever has been conveyed through water, some fortnight has to elapse between the distribution of the water and the occurrence of the disease among the community served by it. But a fortnight after January 5th was the very day on which the first case of fever occurred, and during the fortnight following upon the period January 5th to 20th, i.e., from January 19th to February 3rd, the disease became widely spread throughout Caterham and Redhill, the distribution of the fever being limited to houses supplied by the Caterham Company. There can, he thinks, be no doubt but that they had in the man alluded to the cause of the epidemic which followed. To the Caterham Water Company Dr. Thorne suggested the following remedial measures:—First, to pump their wells dry, if possible; secondly, to scrape the walls of the wells and adits, afterwards scouring them thoroughly with a strong disinfecting fluid; thirdly, thoroughly to cleanse the reservoirs and wash them with disinfectants; and fourthly, to saturate with a similar fluid all the soil in the vicinity of their works where the chalk had been deposited. In view of the manner in which these measures had been carried out, Dr. Thorne, on March 5th, communicated to the several sanitary authorities his opinion that, although in the absence of any test capable of showing the safety of the water, it was difficult to speak on the point with authority, yet he thought the time had arrived when it might again be distributed by the company without danger to the public health. He was glad now to add that nothing had since occurred which led him to believe that the expression of this opinion was premature.

LEGAL INTELLIGENCE.

ROOFING REPAIRS.—At Lambeth County Court last week, before Mr. Pitt Taylor, the case of Hollday v. Bivard was heard. Plaintiff is a builder of Loughborough and Brixton, and defendant resides in Rosendale-terrace, West Dulwich. Plaintiff had repaired the roof of defendant's house, and charged £10 6s. 8d. for the same. Defendant con-

sidered this charge unreasonable, and tendered £7, which was paid into court. Plaintiff declared that the charge was fair, and that it had been sanctioned by Mr. Taylor, surveyor, who had examined the work in company with plaintiff and defendant. The judge, after hearing evidence, considered there had been an overcharge, the sum paid into court being in his opinion sufficient, and gave judgment for defendant.

SERIOUS CHARGE AGAINST A LEICESTER ARCHITECT.—At Leicester Town Hall last week, Thomas Barnard, architect, Leicester, was brought up before the Mayor, charged under the Bankruptcy Act, 1869, with failing to deliver up to Edward Roberts, the trustee of his estate, all real and personal property, books, documents, and papers, as required by law. The particular act upon which that charge was based was the receipt by him of a sum of money, amounting to about £50, some time in January or December, from Mr. Hill, of Loughborough, after the filing of the petition for liquidation. It appeared that Mr. Barnard was appointed arbitrator between two men named Hill and Loveday, and the whole of the labour in connection with the arbitration had been concluded before the filing of the petition. The debtor's charges in connection with that arbitration amounted to £94, and a cheque was given by Hill for £50, which was made payable to Barnard, and endorsed by the latter in order that he might avail himself of that sum for his own purposes, instead of handing it over to the trustee. The Bench decided to adjourn the further hearing of the case. Bail was refused.

CHIPS.

New dispensary premises have just been erected in Silver-street, Lincoln, and were occupied for the first time on Wednesday week. They are Queen Anne in style, the ornamentation being of terracotta.

Plans for the further improvement and re-laying out of the Cattle Market in Gloucester Green, Oxford, rendered necessary by the removal of the city gaol, have been prepared by Mr. Codd, architect, of that city.

A new cemetery is being laid out at Caister, near Great Yarmouth, and the members of the Burial Board, to reduce the expense, have taken upon themselves the duties of surveyor, architect, and clerk of works in laying it out. The ironwork and gates are being supplied by Messrs. Barnard, Bishop & Barnards, of Norwich.

A new road is being constructed at Pembroke Dock for the Government, from the ordnance wharf to the garrison magazine, near which a drill shed, 100ft. by 40ft., is also being erected. Both the works are being carried out, under contract, by Messrs. Jones & John, of that town.

The Chelmsford local Board of Health, on Wednesday week, adopted the plans and estimates prepared by their surveyor, Mr. C. Pertwee, for the joint sewerage of Chelmsford, Springfield, Great Baddow, and Widford, and directed their clerk to apply to the Local Government Board for a total loan of £20,000 for carrying out the scheme.

The Parish Church of Woodton, near Bungay, was reopened last week after restoration. The work has been, a Norfolk journal says, "executed by, and under the superintendence of, Mr. R. Morris, builder, of Ditchingham, who has presented a cover for the font."

An inquest has been held at Chelmsford on the body of Robert Sorrell, aged 65, builder, of Friars-place, Moulsham, who committed suicide on Saturday week by shooting himself through the head. Evidence having been given as to Mr. Sorrell's mental condition, a verdict of suicide while in an unsound state of mind was returned.

The president and fellows of St. John's College, Oxford, have accepted an estimate for the restoration of the front of the College, and the addition of a new hall and kitchen, upon the designs submitted by Mr. G. Gilbert Scott, R.A. The cost will be £40,000, and the works will be commenced in the long vacation.

The work of taking down the spire of the parish church at St. Ives, Hunts, which has been pronounced in a dangerous condition, was commenced last week by the contractors, Messrs. John Saint and Sons, builders.

On Saturday the memorial stones were laid at Elland of a Methodist New Connexion church, which is being erected from the designs of Mr. William Hill, F.R.I.B.A., Leeds. The new church will be in the Gothic style. The cost will be about £4,000, in addition to which about £1,800 has been expended in enlarging the school. The contractors for the new works are Messrs. Armitage and Hodgson, Leeds.

A new post-office is about to be erected at Scarborough. Tenders were advertised for a few weeks since, and the Board of Works have accepted that of Mr. Wetherley, contractor, York, for £5,000.

Our Office Table.

SIR FREDERICK LEIGHTON presided for the first time on Saturday evening at the banquet at the Royal Academy, when the Forty entertained five Princes, as many Ambassadors and Ministers, and a large number of the leading men of the day among their guests. The Earl of Beaconsfield, in responding for her Majesty's Ministers, regretted that the Government had not the means in greater degree of showing its sympathy with the fine arts. He suggested the Wars of the Roses as furnishing materials for the exemplification of the highest art of the English school. English painters and sculptors have in our opinion far better subjects to represent than episodes from a conflict between two aristocratic factions in which the nation had little interest at the time, and has none now. Little was done, either by York or Lancaster, of which Englishmen may feel proud, and the crimes and misfortunes of the principal actors, even when portrayed by Shakespeare himself, somehow fail to awaken our horror or interest in anything like the same degree as the more remote and apocryphal incidents of his greater tragedies.

"The Parish and Church of St. Sepulchre" was the title of a lecture delivered before the London and Middlesex Archaeological Society, by Mr. J. E. Price, on Monday week. The history of the church was traced from its first mention in the Twelfth Century, when it was associated with the Knights of St. John of Jerusalem, to the present time, the numerous and valuable bequests of land towards its repair and support being enumerated. At the time of the Great Fire in 1666, the church was considerably damaged, but by no means destroyed. The casing which covered the original walls has recently been removed, revealing that the masonry was calcined by the heat, the tower arches especially suffering. It was known that the interior of the church was gutted, and that the bells were melted. It had been often asserted that Sir Christopher Wren had little to do with the reconstruction of the church, but Mr. Price refuted this error by reference to Elmes's biography of Wren, to the actual ledgers of Wren now preserved at the Bodleian Library, Oxford, showing the payments made to him by the rector of St. Sepulchre's, and to the vestry minutes, which proved that Sir Christopher restored and partially rebuilt the church on the former plan, that the work was commenced in 1677, and that the total outlay was £4,993 14s. In conclusion, the restoration works recently carried on in the church under the superintendence of Mr. Billing, were described.

At a meeting last week of the Midland Association of Gas Managers at Birmingham, Mr. C. E. Jones, resident engineer and manager of the Chesterfield Waterworks and Gaslight Company, read a paper on "Public Lighting, with special reference to streets." He said the public lighting of the metropolis, except in certain cases, was perfectly disgraceful, and that in Birmingham a state of things existed which was little better. He detailed the results of some experiments he had conducted, showing that by the use of inferior glass in the glazing of lamps there was in some instances a loss of 14·38 per cent. of the illuminating power of the gas, and that in the case of a piece of glass which had become "etched" by the weather and allowed to become dirty, the loss was as much as 83·81. This showed the importance of using good clear glass, of a description capable of resisting the action of the atmosphere, and it also pointed to the importance of cleaning lamps more frequently than was generally done. He thought the electric light in its present stage of development could scarcely be called a competitor with coal gas, where that article was sold reasonably cheap. If coal gas were seven or eight times its present price some degree of anxiety might be felt, but even then the advantages attending the use of gas would preclude the possibility of its being superseded. The cost of the electric light was about seven and a half times that of gas; but it was useful in exceptional circumstances, such as where coal gas was not available.

LAST Friday night a crowded meeting of delegates from the various societies connected with the building trade was held at the Rose, Old Bailey, to consider the advisability of federating the workmen belonging to them throughout the

United Kingdom. The chair was taken by Mr. Thompson, of the Operative Bricklayers' Society. Many thousands of workmen were represented by the delegates present. A resolution was ultimately passed declaring that a federation of the building trades of the United Kingdom was desirable and necessary, and pledging the delegates present to use every effort to give it a practical form. A committee, consisting of two delegates from each trade represented, was elected for the purpose of drawing up a series of questions and proposals to be submitted to the executive councils of all the building trade societies in the United Kingdom, for their consideration, replies, and opinions.

"AN ARCHITECT" dating from 10, Serjeants' Inn, Fleet-street, and whose identity can easily therefore be inferred, writes to the *Cambridge Chronicle*, stating that there is at this moment for sale in London, a large selection of the ancient (14th and 15th century) woodwork of the chapel of Jesus College, Cambridge, bearing the arms and insignia of Bishop Alcock, the founder. There are, he says, four stall ends of vigorous workmanship and great beauty, some eight or ten misericords magnificently carved, and a large quantity of canopy work of old screens, wrought with a delicacy and a spirit that render them valuable examples of mediæval woodwork. It seems that at the close of the last century the stalls of the choir and other portions of the ancient furniture of Jesus College Chapel were taken out and sold, probably to make room for debased Classic work, and that some of the old materials found their way to Landbeach Church, and remained therein, eccentrically disposed about the edifice, till its restoration a year ago. The writer adds that the present rector of Landbeach, Dr. Bryan Walker, at once to augment the repairing funds of his church, and to restore to its rightful position and locality this fine woodwork, entered into negotiations with the Dean of Jesus College, but they could not agree as to price, and the consequence was the woodwork was sent for sale to London. Unexplained, it certainly appears a reflection on the just pride in their past history, and the munificence of the authorities of an ancient college, that they should be unwilling to offer for the recovery of the chapel decorations, presented by one of their most distinguished members, the market price of the woodwork for the adornment of bondoirs and summer houses.

Prof. J. P. HENDERSON, of Loyola College, Baltimore, Prof. J. E. Watson, of Oberlin College, Ohio, and some students of mineralogy, have been testing the capacity of marbles and other monumental stones to withstand the corroding influences of climate. Their first examination was of granite, of which 382 different specimens were tested. While most of these were composed of such materials as would wear tolerably well in the open air, nearly every piece showed a lack of ability to withstand long exposure to rough weather. Marble was then tried, and as Vermont and Italian marbles are most used in the United States for out-door monuments, attention was given chiefly to these. The principal quarries of Vermont are the West Rutland, Sutherland Falls, East Dorset, Pittsford, and Columbian. In point of durability the West Rutland marble was found to take the precedence, and the others followed in the order of their names. They found also that the native Vermont marbles are better adapted to stand the American climate than the Italian, which is rapidly going out of use, and will most likely disappear entirely for outside work.

A DESPATCH from Easton, Pa., states that the cleverest feat of engineering ever attempted in that region has just been successfully carried out. It seems that, owing to their immense weight, the iron shoes, in which rest two of the spans of the long bridge of the Lehigh Valley Railway, had sunk about an inch, throwing the bridge out of grade. The inside masonry of the pier being less solid than the outer casing, it was evident that the depression would continue; accordingly an iron casting, 12ft. long, 3ft. 3in. wide, and 3in. thick, and weighing 7,000lb., was placed under the spans to elevate them, the spans being raised for that purpose by hydraulic jacks. The spans weigh 180 tons each. The spans were raised, the masonry redressed, the castings placed in position, and the spans lowered, without the stoppage of a single train.

The new station extension at Lime-street, Liverpool, is now approaching completion. About three and a half years ago the work of

excavation was begun by Messrs. Taylor and Thompson; Mr. E. W. Ives, C.E., was entrusted with the contract for carrying out the erection of the roof, which was commenced under his direction on the 6th of April, 1878. The whole of the immense roof has been put up at the rate of three bays per month, each bay weighing 62 tons, the work including the removal of the staging, which in itself weighed 510 tons, from one position to another; and it may be an interesting fact to engineers to know that one of these bays was completed in the short space of 5½ days. There are altogether 18 bays in the roof—the iron work weighing somewhere about 1,800 tons—in connection with which there will be 84,000 square feet of glass, four-fifths of which are now completed. The roof is arched, with diagonal struts, and flat bar bottom tie rods. The total rise to the top of the boom is 42ft., and the rise of the tie rod is 25ft., the proportions throughout being exceedingly good. The roof is supported on cast-iron columns, each of which weighs 11 tons. The columns of the old station and new extension are braced together with iron rings, so as to give them greater stability. When completed, as already stated, it will cover the largest area of any station in England, in two clear spans of 200ft. each.

A CORRESPONDENT of the *Citizen* describes the manner in which water-closets and cisterns are ingeniously contrived, in many suburban houses in the metropolis, so as to spread in the most effective manner the germs of enteric fever. He says:—On a large area in the neighborhood of Stoke Newington, Kingsland, and Ball's-pond, several thousand houses have been built, and very many of them have the water-tank over the water-closet, the latter being on the landing, and inside the house; the soil-pipe of the water-closet runs into the drain leading to the main sewer; the waste pipe from the roof is inserted and runs into the soil-pipe, and to flush the water-closet a pipe runs into the tank. By pulling a wire a valve in the bottom of the tank is lifted, and so much of the foul air in the pipe as is not forced by the water into the closet, forces itself through or mixes with the water in the tank, used for drinking and other purposes.

The exhibition of electric lighting apparatus at the Albert Hall was a success so far as such an exhibition could be. Those who attended Mr. Preece's lecture had a unique opportunity of appreciating the effects produced by the various systems of lighting, and the exhibitors are to be thanked for the trouble they have taken with so little prospect of benefit to themselves. Nearly all the machines and lamps hitherto used in the production of the electric light were exhibited, and on the occasion of Mr. Preece's lecture, besides the five Siemens' lamps in the dome and the Jablochhoff lamps around the building, the other lamps were described and their powers displayed by experiment. The effect of the flood of light in such a building as the Albert Hall, crowded with a gaily-dressed audience, may be better imagined than described; but at any rate its advantages over gas were fairly demonstrated.

The *Athenæum* refers to a "mild controversy" which has lately prevailed among visitors to the library of the Anthropological Institute. Dr. E. V. Hayden has presented his magnificent album of photographs of members of 70 Indian tribes of the United States. The chiefs are depicted some with scalping-knives, scalp, and tomahawks, and some in coat-tail costume. Among the Ojibway chiefs is a photograph of Hole in the Sky, and this is declared by some to be no other likeness than that of Prof. Ruskin. At all events it resembles him much. It is not suspected that the photograph of an Indian chief has been abstracted by some amateur since its arrival here, and replaced by that of Mr. Ruskin. It can scarcely be believed that Prof. Hayden has been imposed upon by some American wag, and a *carte* of Mr. Ruskin been foisted on his collection. This can, however, be tested by examining the name of the photographer on the back, and if it proves to belong to the Survey then there is an end to the suspicion of its genuineness, but the resemblance to the enthusiastic art critic remains a matter of curiosity.

MR. HORMUZZ RASSAM has, it is said, discovered a very important cylinder of eight sides, about 20in. in height, and about 6 or 7in. in diameter. This cylinder, which perpetuates a historical inscription covering at least ten years of the reign of Sennacherib, and embracing the

period of that monarch's wars against King Hezekiah, was discovered in a foundation course of the south-west palace, on the mound of Koyunjik, and was probably one of the memorial stones placed there on the completion of the palace. The cylinder, as far as can be inferred from the photographic representations which have arrived in this country, is in an extremely good state of preservation.

CHUBB'S

WROUGHT IRON DOORS,

Fire and Thief-Resisting Strong Rooms, Safes, and Iron Ladders.

THREE PRIZE MEDALS

And Honourable Mentions at PARIS EXHIBITION, 1878.
Illustrated Price Lists post-free.

128, Queen Victoria-street, St. Paul's, E.C.; and
68, St. James's-street, Pall Mall, London.—(Advt.)

CHIPS.

The woodwork of the new high roof of St. Alban's Cathedral being completed and ready for fixing, the contractor has called on the Faculty Committee to decide on the covering, which was deferred in order to see whether an adequate amount would be specially subscribed for lead. This has not yet been done, but enough has been subscribed to induce them to run the risk, large as it is, of doing the work in the way that the subscribers generally desire, and they have ordered lead accordingly. The deficiency of funds is still nearly £4,000, which must be provided by the end of next year.

Extensive improvements are about to be carried out on the Late Norman Church of St. Bartholomew, Winchester, from the designs of Messrs. J. Colson and Sons, of that city. Two bays are to be added to the northern aisle of the nave, the western gallery is to be removed, while the present lath-and-plaster ceiling of the nave will be removed so as to remove the handsome oak timbers of the original roof.

The foundation stone of a new Episcopalian Chapel was laid at Port Patrick, Isle of Man, on Wednesday week. The chapel is being built from the designs of Messrs. Barry and Son, architects. It will be Gothic in style, and will measure 6ft. by 23ft. 120 sittings will be provided at an estimated cost of £750, including land. The contractors are Messrs. Harrison and Kinnig, of Peel, and the chapel is to be completed by November next.

Lewes has followed the example of most other country towns in the south of England in removing the cattle market from the High-street to an inclosure at some little distance. The new market which lies between the railway and St. John's Church was opened on Tuesday. The plans for the market, its buildings, pens, and stalls were prepared by Mr. H. Card, surveyor, of Lewes. The contracts for the excavation and levelling were taken by Mr. James Pickard, St. Ann's, and that for the settling rooms, offices, and fencing was taken by Mr. Harman.

Plans are being prepared by Mr. Hodgson for the sewerage of the town of Wigton.

The foundation stone of a new church for Killinghall, near Harrogate, was laid on Saturday week.

The construction of the sea-wall and breakwater at Newhaven is being rapidly proceeded with. Nearly 400ft. are already constructed, the season having been exceptionally favourable. Two hundred and sixty men are employed on the works. Mr. F. D. Banister is the engineer-in-chief, assisted by Mr. Alfred E. Carey, and Mr. Robinson is the superintendent of works.

The parish church of Coxhill, in the East Riding, was re-opened on Monday week after complete restoration, effected at an outlay of £3,000.

The corporation of Doncaster have decided to adopt a recent report made by Mr. Hawkesley, C.E., on their new waterworks at Ravensfield, and to carry out certain additional works which he has recommended with a view to staying the leakage at their main reservoir.

A stained-glass window has been erected in the north aisle of Maisemore Church, Gloucestershire, by Messrs. A. Gibbs and Co., of London. The subject is our Lord's charge to St. Peter.

The Palmerston Park line of tramways in Dublin was opened for traffic by the Dublin Central Tramway Company on Monday.

The foundation stone of a new vicarage house for the parish of Holy Trinity, Bridgwater, was laid on Thursday week. Messrs. Down and Son are the architects, and Mr. Escott, of North Petherton, is the contractor.

The local board of Bognor have appointed Mr. Marshall clerk of works for the new drainage scheme, at a salary of £3 per week.

A new church is about to be built at Triangle, near Halifax, from the designs of Mr. Barber, of Halifax. It will be in the Early Decorated style, and will consist of nave, with deep chancel, organ-chamber, and clergy and choir vestries.

A series of shops have been erected for a large drapery establishment in St. Mary-street, Weymouth. The buildings are Elizabethan in style, and have been erected from the designs of Mr. R. Crickmay. Mr. L. Bartlett was the contractor.

Messrs. Chubb and Son, the patent lock and safe makers, of Queen Victoria-street, E.C., will publish next week a reprint of the chief correspondence and newspaper articles connected with the recent controversy on English and American locks. The pamphlet contains a preface by Mr. H. W. Chubb, and will be forwarded free on application.

A new recreation ground is being prepared by the Marquis of Bute for presentation to the people of Cardiff, and is expected to be ready for the dedication in about two years. It adjoins the Sophia Garden on the side of the Taff, and is twenty-five acres in extent. The grounds are being laid out under the superintendence of Mr. Pettigrew.

New board schools at Gwernvach were opened by the Aberystwyth School Board on Thursday the 1st inst. The buildings provide for 650 children in three departments, the chief boys' and girls' rooms being each 65ft. by 20ft., and that for the infants 56ft. by 26ft., besides classrooms. The style is Gothic; the walls are of local masonry, with Forest of Dean stone dressings. The architect is Mr. W. D. Blossley, of Cardiff; the clerk of works, Mr. Ridges, of London, and the contractors are Messrs. C. James and Sons, of Bridgend. The cost has been £6 10s. per head.

Great progress is being made by Messrs. Henry Lee and Sons, the contractors for making a south entrance to the Ipswich Dock, in the preparations for the work. The engineer is Mr. Bateman, C.E., of London.

The Court of Common Council of the City have authorised the library committee to take the opinion of a Royal Academician as to the "artistic merit of a picture of Temple Bar," by Robert Dudley, now hanging in the corridor leading to the Guildhall library; and if the committee think after this that the picture is worthy of being possessed by the Corporation they are further authorised to negotiate for its purchase.

The vestry of St. George-the-Martyr, Southwark, are about to build baths and washhouses in the densely populated district of Lock's-fields, Old Kent-road. The plans have been prepared by Mr. Hiscox, surveyor to the vestry, and are estimated to cost £15,000. The principal baths are 93ft. by 28ft., and 45ft. by 25ft.

At a meeting of the Royal Hibernian Academy of Arts Mr. Stephen Catterson Smith has been elected a constituent member, Sir Frederick Leighton, P.R.A., a honorary member, and MM. R. Brunier, Otto Weber, and Victor Gilbert honorary foreign members of the academy.

The annual report of the Baptist Building Fund, presented to the subscribers last week, shows that during the past year thirty-four new chapels have been erected, containing 12,740 sittings, or 8,340 allowing for those in chapels pulled down. The land has cost £12,866, and the buildings £79,090. The outlay on chapels enlarged and improved has been £8,464, and 960 sittings have been added to the accommodation.

The parish church of Brewood, five miles from Wolverhampton, was reopened on Tuesday after partial restoration, from the designs of Mr. G. E. Street, R.A., carried out at a cost of £5,000.

The parish church of St. Mary, Woolwich, was reopened on Sunday week after the substitution of chairs for the old pews, and the removal of the upper gallery.

The Leicester Coffeehouse Company has accepted a tender at £2,943 for the erection of another new house. The architect is Mr. Edward Burgess.

At the last meeting of the sanitary section of the Glasgow Philosophical Society Mr. Alex. Frew, C.E., submitted a proposal for the removal of the sewage of Glasgow and the neighbouring burghs. The scheme consisted in conveying the sewage and rainfall, estimated at 136,782,000 gallons per day by sewer to the corporation ground at Dalnair, where the liquid could be treated by chemicals and the effluent passed to the river. The estimated cost of the works was £594,000, and that of maintenance, exclusive of treatment of sewage at £42,000. In the course of the discussion which followed Lord Provost Collins said "Glasgow must be prepared to lay before next session of Parliament a plan for dealing with at least a portion of the sewage of the city." Dr. J. A. Russell, of Edinburgh, followed with a paper on "Isaac Stone's Pneumatic Sewage System."

The Newry town commissioners on Monday raised the salary of Mr. Meares, town surveyor, to £125 a year.

Trinity Wesleyan Chapel, Harrogate, was recently opened. It is in the Early Decorated style, and has been erected from the designs of Mr. George Woodhouse, architect, of Bolton.

Sandgate Free Church, Ayr, after being decorated and partially reseated, at a cost of £1,500, was reopened on Sunday week.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Institution of Surveyors. Discussion on D. Sturge's paper on "The Disposal of the Sewage of Paris," 8 p.m.

Society of Arts. Cantor Lecture, No. IV., "Recent Advances in Telegraphy," by W. H. Preece.

WEDNESDAY.—Society of Arts. Paper on "The Automatic Railway Brake," by E. D. Barker, 8 p.m.

THURSDAY.—Society of Arts. Sanitary conference. Civil and Mechanical Engineer's Society. G. W. Wilcocks, A.I.C.E., on "Roads and Roadways," 6.30 p.m. Society for the Fine Arts. Lecture by E. P. Loftus Brock, F.S.A., on "The Uses of a Collection of Ancient Engravings," 8 p.m.

Society of Arts. W. H. Perkin on "The History of Alizarine and Allied Colouring Matters," 8 p.m.

FRIDAY.—Society of Arts. Sanitary conference. Royal Institution. Professor Cornu, "Sur l'Étude Optique de l'Elasticité," 9 p.m.

SATURDAY.—Royal Institution. H. H. Statham on "Architecture." Concluding Lecture (No. 4), 3 p.m.

BATH STONE OF BEST QUALITY.

WESTWOOD GROUND, BOX GROUND, CORSHAM DOWN and COMBE DOWN.

RANDELL, SAUNDERS, & CO., LIMITED
Quarrymen and Stone Merchants.

Prices, delivered at any part of the United Kingdom, furnished on application to

BATH STONE OFFICE, CORSHAM, WILTS. [ADVT.]

Holloway's Ointment is not only fitted for healing sores, wounds, and relieving external ailments, but rubbed upon the abdomen it acts as a derivative and thus displays the utmost salutary influence over stomaclic disorders, derangements of the liver, irregularity of the bowels, and other intestine inconveniences which mar man's comfort.

Trade News.

WAGES MOVEMENT.

ALTRINCHAM.—The master painters of Altrincham have given notice to their employes of a reduction of wages of one halfpenny per hour, to come into force on the 1st November next.

BLAKEBURN.—The operative masons, bricksetters, flaggers, slaters, plumbers, glaziers, joiners and other artisans employed in the building trades have either resolved to strike against a reduction of 1d. per hour, or have ceased work already. The stone-masons will receive 12s. per week from the London Central Society, and the others will receive strike pay from the funds of their societies.

CHORLEY.—The joiners of this district struck work on Thursday in last week against the reduction of wages, of which notice was given by the masters six months ago. The reduction is at the rate of 1½d. per hour, with an extension of working hours to 55 per week.

GREENOCK.—The master plumbers of Greenock have intimated to their workmen that on and after the 10th inst. the wages will be reduced 1d. per hour.

HUDDERSFIELD.—The masons of Huddersfield having declined to work 54 hours per week, instead of 49½ as heretofore, and having also refused to consent to arbitration, have been locked out by their employers. They had offered to accept a reduction of 2s. per week rather than work increased hours.

LIVERPOOL.—On Saturday a deputation from the Liverpool operative plasterers waited on the masters for the purpose of coming to an arrangement respecting the reduction of 1d. per hour and an increase of five hours on the week's labour, which was proposed by the masters, and finally left, with the understanding that the operatives should continue working on the exact terms of the masters' first notice of 1d. per hour reduction, and also to commence work at six a.m. instead of seven, "under protest." The operatives will now receive about 5½d. per week less than formerly, with an additional five hours' labour per week.

MERIONETHSHIRE.—Notices reducing the working days to three weekly were posted on Monday at most of the Merionethshire slate quarries. The slate trade continues in a most depressed condition.

WIGAN.—The Wigan painters are dissatisfied with the award of the arbitrator on the reduction in wages proposed by the masters, and did not commence work on Monday. The notices by the masters were that the week's work should be increased from 49½ to 54½ hours, and the rate of wages reduced from 8d. to 7d. per hour, and the arbitrator decided that the hours should be 54½, and the pay 7½d. per hour. The masons, plasterers, plumbers, joiners, and carpenters are still on strike. The joiners have offered to accept either of the following rates: 49½ hours at 7d., or 54½ hours at 8d., but the masters refuse to entertain either. The painters have requested their employers to reopen the arbitration with reference to their rate of wages. The masters, however, at a meeting on Monday afternoon, declined to do so, as they saw no reason for that step being taken.

THE ARTIFICIAL MARBLE COMPANY

(DELAROCHE'S PATENT).

MANUFACTORY AND SHOWROOMS:—VYNER STREET, CAMBRIDGE ROAD, LONDON, E.

ARTIFICIAL MARBLE MANTEL-PIECES, { MADE IN SICILIAN, VIOLET-VEIN, ROUGE, ST. ANN'S, &c.

AT LESS THAN HALF THE PRICE OF REAL MARBLE.

Designs and Prices Post-Free on Application.

A LARGE AND VARIED STOCK ALWAYS KEPT.

N.B.—THE CHEAPEST AND BEST MANTEL-PIECES IN THE MARKET.

THE BUILDING NEWS.

LONDON, FRIDAY, MAY 16, 1879.

DOORS AND DOORWAYS, ANCIENT AND MODERN.

THE South Kensington Museum has acquired, by purchase, a marble doorway from one of the old Genoese palaces, the reputed work of L. da Romero da Campione, bearing date A.D. 1519. Such acquisitions would be all the more valuable did they lead to a deeper practical study of the ways in which those ancient Italian workers made their edifices, not merely splendid but artistic also. In few respects has the genius of inventive and constructive nations and ages been more characteristically illustrated than in their fashions and mechanisms of gates, doorways, and doors, of which, perhaps, the most superb modern illustrations are to be found in the double malachite valves, from the Ural, adorning the Winter Palace at St. Petersburg. A palace, as distinguished from a public edifice, is, of course, a private building, and the degree of luxury represented by its splendour is never more distinctly apparent than in its approaches. Whether, however, in palatial or in humbler dwellings, the door and doorway always constituted among our ancestors important appendages, constructed of various woods, carved, moulded, painted, set, as it were, in frames of decoration, occasionally of almost architectural effect, though the material was only pine, or oak, or ebony, held together by Gothic-headed nails and iron braces. In the older Spanish mansions we find a still greater dignity given to the means of entrance, and, singularly enough, their arrangements very closely resemble those of Herculaneum and Pompeii. There is a hall, with one door opening on the street and another opening on an interior court, the latter of wood or of thin iron, the former of massive wood, enormously heavy, but nearly always wide open during the day, and studded with nails, diamond, square, or round-headed, but invariably turned into one form of decoration or another. It was upon their doors and gates, indeed, that the elder race of Spaniards expended most of their marvellous facility in iron-work. In parts the details seem to have been hammered and in parts chiselled, but upon all the traces are to be detected of Moorish teaching. Singularly enough, however, the gate of the Pantheon at Rome, to this day almost intact, and the only one remaining from antiquity with all its accessories perfect, exhibits similar features. Each of the bronze nails with which it is studded, and which, apart from a low moulding, constitute its sole ornament, is a piece of decoration in itself, with heads representing sun-rays, jewels, and so on, in such elaboration as to become a study. The Pantheon, indeed, of all the Roman structures, was that in which this adornment of bronze was most profusely employed, and in the portals especially. But that, of course, was a national edifice, to which attention has only been for a moment diverted from the family castles, so to describe them, of the feudal age. These were rarely remarkable, in any sense, as works of art, and the celebrated one of Aiguo-Montas may, perhaps, be taken as typical of them all—reproduced as we find it at St. Vicente in Spain, the Mediæval market-place at Brussels, and the Tower of Narbonne—a low-browed arch, leading to another rather more airy, always studded with nails, sometimes plated with iron,

occasionally armed with a portcullis. But these were rather military than domestic gates and doors; and, indeed, the variety of such construction is a large one, for architects have bestowed infinite care and thought upon the apertures, especially of sacred interiors. Those in bronze, of St. Sophia, at Constantinople, have always been regarded as masterpieces of art, with, scarcely less so, those of the tabernacle in the church of St. John, at Flens, in the same material; of St. Mark's, Venice; and the Abbey Church, St. Denis; and, in a word, of St. Sabine, at Rome. London, of course, has long forgotten its gates, except in so far as they are commemorated by the names of streets and thoroughfares, as Ludgate, Bishopsgate, and so forth; but the English never lavished such love upon these works—though many of our cathedrals exhibit good testimony to it—as did the builders of old days, and of the Italian palaces, more particularly those of Genoa, Florence, and Venice. Still, rich in luxury as were these structures, they never brought forth so elaborately the genius of the early builders as did the more religious and monastic constructions of an age coeval with them. But even here, periods of manners, not less than of arts, pass across the perspective. It was considered an extraordinary fact that the gates of Lorient, of the convents on Mount Athos, of the abbeys Cluny and Jumièges, of the Convent of the Holy Fathers at Auxerres, of the Brothers of the Redemption of Slaves at Rome, and of the Cathedral of Marmontier were unfortified, while those of Ivron, Tournours, St. Peter of Barquell, St. Baptist of Laon, and St. Martin d'Anchy, under the name of gates, were so many fortresses, with towers, barbicans, covered ways, and every preparation of defence. Yet, almost at the same time, we have houses of sanctuary so respected, even by the brigand classes, that their doors of solid silver, or other metal, thickly-gilded, were left unguarded by night.

Art, among its imaginations, has seldom put them to a more varied use than in the architecture and materials of gates. It has given them endless forms—in Latin and Gothic churches, in Greek and Roman dwelling houses—in cathedrals and at the entrances of cities; in the shape of triumphal arches; for palaces and castles, for cemeteries and catacombs. It has made them of marble, granite, bronze, ivory, malachite, silver, and even gold, of maple, mahogany, oak, and cedar. At Grotto-Ferrara, near Rome, was recently discovered a magnificent portico, with doors of bronze,—though some were of wood moving on hinges, and covered with plates of silver, while others belonging to the basilica of St. Mary the Great were of silver, solid. Those of St. Constantine are plated with the precious metals, damascened in semi-Oriental patterns, while those of St. Sabine, already referred to, are of wood, but literally pictures and frames of sculpture, in designs admirably followed in St. Anne, at Paris, and in the modernised porch of the Cathedral of Rouen. This last, however, exhibits some features of its own worth notice. It is of oak, panelled, with a border of sixteenth century arabesque, exquisitely carved, but unhappily daubed over with paint. The architect originally employed recommended filling up the crevices with gun, and laying a light cover of oil upon the gun; but he was superseded, and another revivalist engaged, who daubed the delicate surface with a legend, in abominable colour, of the Tree of Jesse. Still, nothing can disgrace the beautiful forms of the jambs and lutelets, of the birds and cherubs, of the flowers and plants, wrought originally in the virgin oak. In its proportions, however, though the enrichment be Gothic, this doorway precisely resembles that which has just now been brought from Genoa, and another belonging to the Church of St. Mary-the-Great, at

Rome, in wood, plated with bronze, and having projecting piers, with figures of lions, in cast metal, recumbent upon them. The porch, however, must not be confounded with the gate. The former has, in all epochs, and under every dispensation, afforded an opportunity of interminable decoration and display, while, of the latter few examples remain to contest the palm of excellence with those of Gioberti. Nor, again, must a gate be confounded with a door, and of this we have two interesting illustrations belonging to the olden time, one from Germany, and another from France. The former opens upon a suite of ground-floor rooms in the Grand Ducal Château of Baden. It is in perfect consonance with the rest of the structure—a world of wooden architecture, overlaid by one of stone—of timber roofs, of carved panels, of oaken mouldings, of unconcealed rafters, of coffered ceilings, of sculptured or moulded friezes, and, consequently, of doors to match—lofty and heavy, with a ponderous transverse bar half-way down, occasional inlays of walnut, pine, and ebony, a lock of monstrous size, and hinges covering a third of the surface. The latter, lately unearthed at Toulouse, is of uncertain date, folds back on either side, is very simply carved, and, to all appearance, was painted of a natural white. Both of these, however, are confronted by the design of a French architect, César Daly, who wrought the noble gates of the Hotel Demidoff, in Paris. He boldly lays it down as an axiom that in the construction of gates bronze is almost the only proper material to be employed. The Egyptians understood its value; the Greeks constructed a temple with it three centuries before the first stone of the Parthenon was laid; the Romans roofed their festal halls with bronze. More to the purpose is the fact that the doors of Notre Dame and of a hundred other shrines, celebrated throughout the civilised world, are thus composed, together with the famous Grille of St. Germain l'Auxerrois; but the Demidoff gates are actually of hammered iron, finished off with cast-iron ornaments, perforated into patterns while red-hot, manipulated to an extreme fineness, and yet of marvellous strength. Another door, the preservation of which is due to the same artist, is that of the Abbey of "St. John of the Cabbages," in the valley of the Lower Rhine, eight or nine centuries old. The work is supposed to be as old as the edifice itself, or, at any rate, exemplifies the highest state of the art as it existed in the first half of the twelfth century, when it had been comparatively obscured during the process of a long decline. It is composed of upright planks, set in a frame of solid stone, and it was once ornamented and strengthened by metal circles and scrolls, partly symbolic, and most ingeniously wrought together. Some of this antique metal work, when analysed, is really amazing, on account of its perfection in detail, and thorough originality in the idea. Schweighouiser, in his book on Alsace, declares that there are parts of it which would literally bear examination by the microscope, and yet it was hand-work from beginning to end. The relics in wood, however, belonging to this class are not the less worth examination. That attached to the Sacristy of Rouen Cathedral—a thirteenth century specimen—is a marvel of simplicity, elegance, and that kind of character which throws a halo round every variety of ecclesiastical art. The wooden doors, indeed, of the twelfth and thirteenth centuries are well-deserving of notice from every point of view. Sometimes they were constructed of simple planks placed upright, side by side, carvel fashion, and held together either by transverse pieces or iron bracings. But they had to be hung, and their hangings had to be socketed in the stone, and, by degrees, this furniture had to be made, in its way, ornamental, whether by

bevellings of the timber, or ramifications of the iron-work upholding it, and so branches, fruit, flowers, emblems, and an entire allegory of mediævalism grew upon the rough surface of the iron. The Cathedral of Rouen, in fact, affords several examples of Middle Age doors, in the construction of which iron has an important part. Some of them, however, have been modernised and vulgarised of late, and the hammer of a nineteenth century blacksmith has, in various instances, broken away a piece of work of which Quentin Matsys himself might have been proud. Still, the great door of Rouen retains its character, notwithstanding the coarse coat of paint by which it has been both discoloured and disfigured. The joints between the planks, it is true, are no longer to be distinguished; the locks and bolts are battered, but the ring hangs in its place; and the circular ornament, for which no one has ever yet found a meaning, is, strange to say, untouched. This door is in itself, says M. Daly, "a lesson in architecture," and certainly nothing can be at the same time more simple and more significant. These are principles we find repeated in the gates and doors and doorways of Chartres—not long ago destroyed by an incendiary—of Florence, Palermo, and Perugia, the three last being of richly sculptured marble, in close resemblance with that lately brought from Genoa to South Kensington. The singularly high and narrow entrances into the palaces and churches of Anay-le-Franc, the market gates of Brussels and of Berne, the castle gates at Cadaillee and Gaillon, with the more curious gates of Lisbon, suggest much that is remarkable, as exemplifying so many fashions of taste, if not so many schools of thought. In the East, of course, where the word "door" is mentioned it often means no more than a pair of curtains, but, taking the term literally, it may still have a number of different applications, as in the Latin Gate of Rome, the War Gate of Rheims, the Gate of France at St. Martin-le-Vinoux, the doors of the hôtels Cluny and Sens, and the Mycenaean, Ephesian, and Nicaean gates. In Turkey, we know, the "Porte" originally signified the entry to a palace, though it has since become a synonym for the Government of the Ottoman empire; but these translations from the real to the figurative belong only to the East, and although in a poem "the ivory door of dreams" may be tolerated, the solid interest of the subject begins with the entrances provided in past and present times, whether for cathedral or church, palace or prison, Gothic castle, or ordinary modern abode. The gate or the door figures largely, as we have said, in the chronicles of both arts and manners in every civilised country. Moreover, a wonderful literature connected with this sole subject, neglected though it be in modern days, exists.

THE CONSTRUCTION OF THEATRES AND MUSIC-HALLS.

SOME regulations for the better construction of theatres, music-halls, and other like places of resort, and for the protection of the public frequenting them, have been talked of repeatedly within the last few years, and now we have the first instalment towards a code of regulations issued by the Metropolitan Board of Works under the Metropolitan Management and Building Acts Amendment Act, 1878. The new regulations were made at a meeting of the Board on the 2nd inst., and comprise seventeen clauses in all. These we may briefly notice, confining our attention chiefly to those which have most direct bearing upon the planning and construction of buildings of the class referred to. The proprietors and stage-managers of theatres and music-halls are essentially conventional in their habits and thoughts; hence

we have been accustomed to see, despite the repeated casualties from fire and panic, the auditorium of a theatre built in the flimsiest manner, while behind the proscenium the materials and construction are of a still worse description. Wooden partitions not unfrequently divide the passages and gangways, while drapery and tinsel of the most inflammable kind conceal the temporary expedients on the stage. As regards planning, the theatre does not admit of much that is new. Its shape has to be governed by the primary conditions of sound and vision, while its size or accommodation is regulated in like manner by the width of the stage opening. It is essential that the part of the house which directly faces the stage should be within a moderate distance, say, 60ft.; that the shape should be either based on the isacoustic curve, or upon the conventional horse-shoe form, and that the usual passages and staircases should be placed in positions to provide for the readiest ingress and egress. But though the plan does not admit of much invention, the construction calls for a thorough reform in details at least. The Regulations now before us apply to all "places of public resort within the metropolis for the performance" of stage plays, and "to all houses, rooms, or other places containing a superficial area for the accommodation of the public of not less than 500 square feet," so that a room of 25ft. long by 20ft. broad can be brought under these restrictions if it be opened or used for public dancing or other entertainment under authority of letters patent or licensed for such purpose for the first time after the 22nd day of July, 1878. Regulation II. requires that henceforth every person who is desirous of opening a house or place of entertainment or resort within the metropolis, or any room of not less than 500 square feet, shall give notice of his intention to the Metropolitan Board of Works; and it further requires that plans, elevations, and sections of such house, room, or place of public resort, or of the premises of which such may form part, drawn to a scale of not less than $\frac{1}{4}$ th of an inch to a foot, and a block plan showing its position in relation to adjacent premises drawn to a scale of not less than 1 in. to 20ft., must be submitted to the Board. It recites "In the case of new buildings, or buildings to be adapted as a place of public resort, these drawings must be also accompanied by a specification of the works to be executed, describing the materials to be employed and the mode of construction to be adopted, together with such other particulars as may be necessary to enable the Board and its officers to judge whether the requirements of these regulations will, when the building has been completed, have been complied with." The notice has also to be accompanied by a "detailed statement of the respective numbers to be accommodated in the several portions of the house or other place, and of the area to be assigned to each person, which shall not be less than 1ft. 8in. by 1ft. 6in. in the galleries; nor less than 2ft. 4in. by 1ft. 8in. in the other parts of the house, room, or other place of resort." No one can complain of these requirements in ordinary cases; a statement of the nature of the interest in the premises of the person applying, and the schedule of numbers to be accommodated, and the area assigned to each, seem to us to be highly necessary to insure public security in these buildings; but there is one point about which architects will have some reason to complain, namely that quoted by us above, in which a specification of the works to be executed and other detailed particulars are to be submitted. Why should an architect be subjected to this kind of control? In some instances such an ordeal would be simply preposterous; it would be a tacit admission of the superior skill and experience of the officers of the Board—an assumption that may be quite unwarranted, and which

many architects who had built theatres could fairly resent. We may suggest therefore the words in parenthesis, "unless an architect be employed," ought in justice to be inserted in this part of the clause. We contend that the submission of the plans and sections of a building would, or ought to be, when a respectable architect was engaged, ample guarantee for the conscientious use of good materials and proper modes of construction adopted. The area to be allotted to each person in the gallery is a trifle over 2 square feet, and to each person in the other parts about $3\frac{1}{4}$ square feet—areas that at present are not attempted in the majority of London theatres. We believe 2 square feet to every grown-up person a not very ample allowance for passages and stairs, but the space allowed in the regulations is ample. Capt. Shaw has laid it down that for every hundred persons accommodated, the passages, halls, and stairs should not be less than 250 square feet. The regulation touching walls is that every house or room shall be inclosed with external walls of brick or stone, or partly of each, and the thickness to be not less than that prescribed by the Building Act for walls of similar height and length of the warehouse class; the proscenium wall of any house is by Regulation IV. to be of brick not less than 13in. in thickness, carried up to a height of 3ft. above the roof, and carried down below the stage to the level of foundation of external walls. Only a doorway into the orchestra and one doorway on each side of the stage, for communication with the auditorium, are to be made through it; these are to be not more than 3ft. 6in. wide, and to be closed with iron doors fixed without woodwork, and the decorations of the proscenium are to be of fire-resisting materials. We hope the last provision will give rise to a better and more truthful mode of stage decoration. Regulation V. provides for the support and inclosing every staircase for the use of audience by brick walls; and all staircases and floors to be of fire-resisting materials. It also provides that:—

"No staircase, internal corridor, or passage-way, for the use of the audience, shall be less than 4ft. 6in. wide. Every staircase, corridor, or passage-way for the use of the audience, and which communicates with any portion of the house, intended for the accommodation of a larger number of the audience than four hundred, shall be increased in width by 6in. for every additional 100 persons, until a maximum width of 9ft. be obtained. Provided always that in every case where the staircases are 6ft. wide and upwards a dividing hand-rail shall be provided.

"A clear passage or gangway, of not less than 3ft. wide, shall be reserved round every part appropriated to the audience, except that next the proscenium or place of performance."

These are wise precautions, and will do much towards promoting roomy places of amusement, and in allaying public fear. No. VI. is to the effect that all ironwork is to be protected against the action of fire, but the means are left to the Board. The VIIth clause treats of means of exit, and provides that wherever a portion of the audience is "accommodated over or at a higher level than others of the audience, a separate means of exit of the width prescribed for staircases or passages, and communicating directly with the street, shall be provided from each floor," separate tiers of boxes are consequently reckoned together as forming one floor, and one additional exit at the least, communicating with different levels and directly leading to the street, is to be provided. All doors and barriers are to open outwards.

Sanitary details have not been overlooked. We find that as regards warming, hot-water only at low pressure is to be used where artificial heating is employed; that all openings for ventilation shall be shown on the plans and described, and be subject to the Board's approval; that no workshop, &c., shall be formed over the auditorium or

under it; no scene-dock or property-room to be permitted within any house unless separated by fire-proof means; that where there are no fire-mains on constant supply two cisterns shall be provided on top of the proscenium wall, or at some approved place, each capable of holding 250 gallons of water for every 100 persons, and fire-mains in connection with hydrants to extend round the whole building; and that no white metal pipes are to be used in any part of the building. The concluding regulations require notice to be given to the Board of any intended alterations or additions to any building in respect of which the Board may have granted a certificate of approval. The notice in such a case is to be accompanied by plans, elevations, and sections, showing the proposed alterations, and also by a specification; but here again we cannot see why the latter document is to be submitted in every case. The Board, however, intimates in the last clause that it may in certain cases "dispense with or modify its regulations," that applications with this object are to be in writing and state the reasons why such modifications should be made.

These regulations, of which we have here given the purport, will, if enforced with moderation and a due regard to the last clause, produce a very beneficial change in buildings of this class. Up to the present time, notwithstanding the rules issued by the Lord Chamberlain to be observed by the houses licensed by him, there has been a deplorable disregard of common structural and sanitary precautions. The proscenium-wall and the separation of the auditorium from the stage itself has not been considered with any care, passages and staircases have been constructed without any independent support and safety of their own, openings for exit have either been absurdly inadequate to the accommodation of the house, or so badly placed that loss of life is rendered almost imminent in case of emergency; doors are made to open inwards, while every means of ventilation is neglected or rendered abortive by the desire to prevent draught. We believe that the adoption of such judicious regulations without unnecessary restrictions would bring about a desirable change in structures of this kind, not only promoting more substantial buildings, but creating an inducement for more truthful architectural decoration.

THE PICTURES AT THE ROYAL ACADEMY.—II.

ERNEST CROFT'S picture (No. 613) of the "Evening of the Battle of Waterloo," is, in all respects, a satisfactory representation of what might have taken place at that momentous time. The moment chosen is when Napoleon is quitting his carriage, which he did in such haste that he left his hat behind him, to be found by the Prussians who took possession of the carriage and its contents a few moments after he had quitted it. The painter represents him as just about to mount a horse, brought by one of his officers for his escape. The gunners to the left have just limbered up and are off, while the guards to the right are heroically struggling to keep back the coming Prussians till the Emperor has gone. It is a stirring incident which has lost nothing by Mr. Croft's vivid interpretation. There is an immense variety of expression all naturally given. The subject, though some of its details are doubtful as facts of history, is adequately treated. Elizabeth Butler (*née* Thompson), shows her usual power in "Listed for the Connaught Rangers," recruiting in Ireland. A sergeant, accompanied by a couple of other soldiers, and a drummer-boy, are marching along a heavy road to join headquarters, with two recruits of different dispositions, through a desolate out-of-the-way Irish moor. The man on the left looks back

wistfully at his distant home, while his companion steps out boldly and carelessly, leaving no cheerful memories behind. The aspect of neither escapes the watchful eye of the sergeant who marches between them. By no means the worst part of the picture is the excellent landscape through which the party passes. Utter desolation, well-nigh without hope, is the portion of "The Penitent," by Luke Fildes (No. 63), returned to the home she left in her infatuation. It is shut up and deserted. There she kneels with head buried in her hands, with broken heart, yearning for comfort. How likely she is to get any from her former neighbours may be guessed from the groups of gossips about the place; even the children are more inquisitive than compassionate. The prosperous farmer on his big cart-horse, with his little boy upon him, will in a minute have passed on with no more than a cursory inquiry. There is plenty of interest, however felt by the women of the village. That ugly old crone at the back and the buxom farmer's wife who is haranguing the bystanders, have nothing too bad to say of their erring sister. Each of them could have told long ago "what was to be expected of a girl like that." But she heeds them not; her grief and shame are too absorbing. Perhaps it would have been better if the man and horse had not formed quite so important a part of the picture; but no doubt the artist intentionally and rightly put the erring sister somewhat in the background, the better to express her lonely situation; for, after all, the subject of the picture is not only the return of the Penitent, but how little pity is extended to an erring sister, however bitterly she does repent, and however much she tries to amend. Of a very different character is the wretchedness of the poor fellow drawn by Mr. Weeks (No. 76). His better half and her old servant are having a thorough clean-up to their hearts' content. Well may he exclaim, "Oh wretched day, beyond expressing! to me a day the most distressing. This slopping." He does not get much pity from his partner in life, as he sits perched on a piece of furniture to get out of the wet, her cheerful raillery only adding to his misery; the hopeless confusion of the furniture heaped up any how completes the whimsical scene. H. T. Wells exhibits a delightful couple of fair young ladies in the "Laurel Walk," (No. 331.) Though they alone are seen strolling among the laurels which shade them from the sun, there are doubtless others beside them in the grove, unless their bright eyes mislead us, though the elder of the two pretends to be so interested in her book. "The Old Stone Breaker" (No. 55) is also good, though rather wanting in life. P. H. Calderon comes out this year chiefly as portrait-painter with a fair amount of success. Family groups with fancy names seem to be coming into fashion, with the inevitable result that nearly all the people seem to be trying to look as if they were not having their portraits taken. Thus in 268 the wife and children of C. J. Lambert are made to pose in "A Voyage Round the World" as listening, though most of them are not, to an interesting tale. It is also all but inevitable that in such compositions the same sort of idea will strike many artists, and so in the present exhibition there are three of this description. As portraits of a charming mother and sweet little girl just come in from a walk in the flowery meadows, A. D. Leslie's "Alice in Wonderland" (No. 72) is delightful. Mr. Leslie's last picture is "Naughty Kitty" (336.) This also has only two figures, mother and daughter in a quiet garden. The expression of Mrs. Puss, not quite without anxiety as she watches the child trying to make little Kitty good by her caresses, is very natural. G. E. Hicks exhibits the third similar and well-painted group of a

mother reading to her children. "Twilight," (No. 325) by P. H. Calderon, is scarcely up to his usual high standard. There is no lack of spirit and incident in A. C. Gow's "No Surrender." After a desperate fight, how desperate can be seen by the wounded and dying; a small band has retired into the very roof of the building. One resolute warrior stands with his gun pointed to shoot the first man that tries to prevent his comrades from pulling up the ladder through the trapdoor, and so cutting themselves off from immediate attack. None of those brave fellows will be taken alive. Eyre Crowe's most meritorious work is No. 301. Marat, as was his wont, is represented as seated in his bath, over which a board is placed, writing his correspondence. Charlotte Corday, had tried vainly two or three times to get admittance. At last he heard her voice and ordered her to be called in. After interesting him by giving him the names of certain Girondist deputies in exile at Caen, which he took down to have them brought to the guillotine, "she stabbed him with a knife which she had concealed for that purpose." It is not the death itself that is described, but simply her entry into the room. Marat, with his wicked face, turning round in something of suspicion and fear to receive her, but is calmed by the steady quietness of her demeanour. (201) "Bluecoat boys returning from their holidays" is a pretty picture; but we do not care for either (443) "The Execution of the Duc d'Enghien in 1804," which is too low in colour and tame, or (1041) "The Queen of the May," a bit of common life which could only be redeemed by very skilful and characteristic treatment. No. 1039 is a wedding scene of the middle of last century. The time is winter, the snow lying thick upon the ground, the young bridegroom has just mounted and is holding his bride before him, seated on a pillion; round them, mounted, are the squires of the neighbourhood, while the peasant girls are giving them a farewell greeting. The old father and mother stand, sorry at their own loss, at the gate to see the last of their darling. Seymour Lucas's "Gordon Riots" (No. 25) puts one in mind of the pictures Copley loved to paint. The enormities committed by the mob are hinted at by the collection of valuable furniture and objects of art heaped in one corner of the street among the dead bodies, probably of some of the robbers. Amid burning houses and the tremendous roar of the authors of those horrible scenes which disgraced that extraordinary time of anarchy, the Riot Act having been read by the worthy magistrate who rides in the midst of the soldiers, and whose alarm is well contrasted with the quiet coolness of his professional companions, the mob at last is brought to bay by the platoon fire of guards. There is great breadth and character in the "Breton Quarryworkers" (No. 123), by G. F. Munn. There are few better bits of drawings in the collection. The next picture, "Adversity," by T. Sant, is too well known to need any description; it is a most beautiful work. All of H. W. K. Davis's landscapes are good. "Cutting Forage on the French Coast" strikes us as one of the best: it is a harvest scene by the seaside, the tide coming in fresh and brisk. Three fine horses are enjoying themselves in the rich grass till wanted. The finish of the foreground, with its poppies, clover, daisies, and various grasses, is as high and true as possible. Country of a very different kind, but equally well transferred to the canvas, is shown in No. 615, where a white cow and calf, admirably painted, have strayed in the moorland. No. 935, "Picardy Sheep," should not be passed over. Of his English scenery the best is (No. 1,396) "Cloud and Sunshine." Rich, fat, slightly undulating pasture land; the summer storm having just passed over and left the green glades greener still; the

bright hot sun making all brighter now that the dark clouds are scudding away, much to the contentment of the flock of rooks who have just resumed their work. The landscape by the door on the opposite side of the room, "The Woodland Road" (1,400), by J. W. Oakes, is a fine robust drawing of oak-eland country. In all the more elaborate landscapes, especially those of the rising school, such as have been purchased by the trustees of the Chantrey Trust, there is a tendency to exaggerate the spectroscopic effect, so much so that the trees in the foreground seem in most cases to come right out of the frame, suggesting, perhaps wrongly, a liberal use of photography. Henry Moore, in "By Stress of Weather" (No. 75), has a splendid and most refined drawing of rough water, the boats just entering harbour having enough to do to hold their own with the growing waves. The tone of colour is subdued, according to the limits that this refined artist has imposed upon himself. "Calming Down" (No. 116), is also well worthy of notice. All the pictures exhibited by J. C. Horsley, except No. 168 "A Trespasser," are portraits. This is a very pretty picture. A very grand madam comes in from her drive, and upon entering her bedroom, where her dress, of most gorgeous description, is lying on the snowy bed, poor tired puss has made herself particularly comfortable in its folds, which she has arranged suitably for the purpose, more to her own satisfaction than that of her mistress. Mr. E. Nicol always gives some humorous examples of character. His "Interviewing a Member" is an excellent instance. The unfortunate member, who is dressed in pink ready to start with the hounds has to endure the prosing of the farmers and others of his village, keeping his temper as well as circumstances will allow. The meeting evidently have no idea of hurrying themselves, so that he might just as well be seated. It is needless to say that the details of furniture, dress, &c., are all conscientiously and faithfully worked out, to the corduroy and pearl buttons of the deaf old fellow who is standing in front. Old Shippers would not seem at first thought a very promising subject, and yet Charles Robinson has made an amusing, and in some sort beautiful, picture of the "Shoes of the Faithful." All these taken off the feet of the men who have entered the Mosque to pray, are arranged in quaint order in the Vestibule under the guardianship of a fine Persian cat and her two sleepy kittens who enjoy the nice warm corner. Through a beautiful lattice-work screen we get a peep at the blue sky and flowers of the temple garden. T. M. Rooke's series of incidents in the life of Ahab (967 to 992) are finished with the elaboration of mediæval miniatures. They show an intimate acquaintance with the minutest details of Assyrian costume and architecture, so far as they have been made known to us by the discoveries at Nimroud, &c., and considerable success in their adaptation to a well known history. The representations begin with Ahab's wanting Naboth's vineyard, and end in his wife's body being east to the dogs in the same spot. "St. Simeon Stylites" (1,005), by G. P. Jacob-Hood, is well imagined. We cannot say as much for C. W. Cope's "Country Club Meeting in the Old Time," where all the guests, listening to the tale of the wit of the village, are meant to be laughing, but are really made uniformly to grin idiotically. It is not every one who can draw a tolerable laughing audience. It was almost too much for Hogarth. The best figure is that of the storyteller himself, whose back is turned, and so most of the humour is left to the imagination. The table-cloth hangs in such massy folds that it might, if it looked like anything but thick paint, be made of quilted blanket. There is not much doubt of the correct verdict to be pronounced upon the "Fox

Terrier" (No. 1374), by Percy Macquoid, though the evidence is only circumstantial. If the remnants of the lobster are not enough, his look will condemn him, and so would that of the Absconded One, by Frank Holl, (No. 1385). We should doubt if many men who run away ever feel such anguish—suicidal, one would think, in its determination—as is expressed in the unhappy occupant of the 1st class carriage in the Dover express. Ruined in love, in fame, and for fortune would be a better title. The agony is piled on rather too heavily for anything less. Notwithstanding much that there is undoubtedly worthy of praise in R. W. Macbeth's "Sardine Fishery" (1,430), we cannot altogether admire it. There is absolutely no transparency in the water, and the surface is very imperfectly rendered. Still there is a good deal of freshness and life about the whole scene, the boats going out, the women mending the nets, stopping their work to bid a cheerful good-bye to their friends afloat; the disgust of the young fellow prevented by his injured arm from going with his comrades. Mr. Macbeth also exhibits several etchings.

ARCHITECTURE AT THE ROYAL ACADEMY.

(THIRD NOTICE.)

IN resuming our notes upon the architectural drawings in this year's Academy, we may remark the very temperate character of most of the domestic works. Among these we may mention Mr. Ewan Christian's "Glyndebourne, Sussex" (1,068), a well massed red brick and tiled house in Late Gothic, pleasingly exhibited in a water-colour drawing. The design shows some additions to a house of remarkably quiet pretensions, the grouping, windows, and gables are all of a character well known to the student of our Domestic Gothic. We have already remarked upon another house just below it (1,069) in a less commonplace style, and we now turn to (1,074) "Harestone, Caterham, Surrey," by Mr. John Sulman, in which a thoroughly Domestic type has been handled with considerable freedom and breadth, notwithstanding the introduction of certain features of a questionable kind. The broad and quiet rendering of the brick walls and stone bay windows of return front has been spoilt by a queerly-placed band of stone, too low to form a necking or an impost, and by the enthipped treatment of the gable ends. There is much to commend in the drawing and colouring, which have a sharpness and delicacy that add to the effect. Mr. R. W. Edis also, in his "New House at Eastbourne," the porch of which we illustrated last year, has not ventured out of the safe but beaten track of English Domestic Gothic. His new house is in red brick and stone, in a sensible and freely-treated kind of Elizabethan; the grouping is good, but the details of entrance side hardly appear to harmonise with the very plain and almost commonplace front. We take this work as it is to be a commonsense treatment for a country house, in which no attempt has been made to be either quaintly picturesque or *negligé*. Contrasting with these, we note several attempts at half-timbered buildings, which the old Kent and Sussex houses have rather suggested than inspired. Mr. John Robinson's "View of Willey's—at Heath, Kent" (1,096), in a rather faint ink drawing that scarcely does justice to it, is more clever in the grouping of parts than it can be said to have seized the true *motif* of the timbering, while the broken gable in the return front does not commend itself as a particularly happy mode of roofing the projection. Turning to Messrs. Dodgshun & Unsworth's design for "Shepherd's Spring, Hants" (1,116), we notice a large house in which the timbering is carried to an excess in the upper story, and the authors appear to have lost

sight of the structural value of framework altogether, in introducing a series of timbers placed anglewise at the lower corners of their gabled projection. These, and the cutting up of the brick chimney shafts with vertical prismatic-shaped arrises, produce an unmeaning character to an otherwise good design in which we notice in pleasing contrast a very well treated arched porch. If the feeling which is displayed in the solid basement of this building had been carried up a much better result might have been obtained. No. 1,130 shows a "House in the Third Avenue, Brighton," by Mr. W. Galsworthy Davie. All that we need say of this design is that it is a pleasing variation in red brick upon the monotonous white brick and stucco residences of a rising suburb of Brighton, though we can hardly understand the shield-like patches between the windows. Mr. T. E. Collett, in his "Houses at Wandsworth" (1,138) adheres to the kind of Renaissance which he has successfully worked in of late. In the present instance there is an unpleasant broken appearance about the gables: the centre scarcely seems to belong to the wings it is so low, and a little more connection between the parts is needed. In Mr. Collett's hands the style has certainly elements that may be turned to account. There is certainly nothing in it approaching the daintiness or humour we find in Messrs. George and Peto's, or Mr. Shaw's work, nor, on the other hand, can we find fault with anything that is cold, hard, or meagre; at all events, we regard this treatment of the style as one adapted for large houses in stone or brick localities. It is essentially a distinct phase from the half-timbered style before mentioned. Mr. Collett's "Three Lodges" (1,093) are exceedingly picturesque studies, and drawn with considerable care and feeling. We may just mention two other designs for country residences: one is a design by Mr. J. Langham, illustrating what we have before remarked regarding the excessively restless and fidgetty striving to produce variety, even by artists of Mr. Langham's *calibre*. The parts of the house seem to wrestle with each other, and though clever in detail, there is a painful sense of crowding and unquietness. In the small plan which accompanies the design, we fail to remark any special skill, and the entrance and hall are not happy. Yet the drawing quite sustains the author's reputation. The other work is "The Grange, East Sheen, Surrey" (1,175), by Mr. E. Ingress Bell, where there is decided repose and good grouping of parts, though comparatively little that is striking in feature. We notice, however, a difference in the treatment of gables, a source of variety, we may remark, that has become a positive weakness in the hands of many young architects. In another direction, we notice Messrs. Dunn and Hanson's view of St. Gregory's Church, Monastery, and College, at Downside (1,081), in that particularly safe style of Gothic about which there can be very little said, and certainly nothing to object to. The bird's-eye view is very well drawn, but hung rather high for examination; the grouping is skilfully managed, and the detail we can well take on trust. No. 1,088 attracts notice by its vigorous drawing rather than by any great merit that the design possesses for its purpose, though we must acknowledge a thoroughly artistic, if rather wild, French Gothic feeling in the massing and details. It is merely an academic sketch, being the design for a "Convalescent Hospital on the sea coast," by Mr. Eldon Deane, and as such it certainly forecasts some good work from its author, evincing power in composition if not in adaptation. A very pleasing sketch of alteration and additions to "St. Mary's Church, Monmouth," is exhibited by Mr. Street, R.A., the new chancel of which, with its richly traceried window, the transept end, and side aisles are grouped together in a charming

manner. A few water-colour sketches demand notice. Mr. Wyke Bayliss sends two rather heavily coloured interiors, one (1,090) of "Trèves Cathedral," and the other (1,105) of "Strasbourg Cathedral." They are both the work of an artist, though scarcely architectural drawings. Mr. Aitchison's "Interior of St. Mark's, Venice (1,085), is a rather washy-looking drawing, feelingly done but wanting in decision of detail. Perhaps one of the best interior drawings in colour, is Mr. F. W. Suggate's "Interior of Henry VII. Chapel" (1,070), a rich piece of colouring of great depth; a little too black perhaps, but conscientious in drawing. Another clever sketch by Mr. Street represents the north-east view of Holmbury St. Mary Church, Surrey (1,107). It is a very picturesque type of a village church with a low shingle spire, broached, a simple row of lights appearing round the low tower, also apparently of timber. The deep chancel and a gabled end to the aisle have been skilfully adapted to the sloped ground. No. 1,104, "The Grand Staircase of Shakespeare Memorial, Stratford-on-Avon," has a more than usual interest just now, and the drawing of the architects, Messrs. Dodgshun and Unsworth, although hung high, shows the staircase doubtless at its best. Exception must be taken to the flat arch of hall through which the view is taken; also the series of pointed arches that form the side or ramp of the stairs has the effect all Gothic areading has when adopted for interiors. It looks weak and strained, though the detail appears excellent, and the drawing is quietly coloured. Hung rather low are two interior views in sepia of "Lancing College Chapel" (1,108), by Messrs. R. H. Carpenter and B. Ingelow. They are softly coloured, and represent the groining, pure and good of its kind, though rather cryptlike in the drawings. Mr. Ernest Lee's "Cottages at Midhurst" are unpretending, but meritorious; while Mr. S. J. Nicholl's "Chapel in Catholic Cemetery, Clitheroe" (1,118), is an exceedingly clever treatment for a building that usually aspires too much, if it does not occasionally minnie a parish church. The timber treatment of the spandrels of open porch, which extends along its front, and the simple flèche and hipped end of roof strike us as very appropriate. In this connection we may refer to Mr. J. Martin Brook's "Design for Lych Gate" (1,123), a rather weakly-looking drawing in brown, but showing a moderate and carefully treated design in Gothic. Mr. Henry Walker exhibits one or two noteworthy buildings. No. 1,127 is a line drawing of an Early English interior—"Design for Potternewton Church, Leeds," and the only fault we have to find with it is the rather massively and over-membered chancel arch. His other and more important exhibit is (1,146) a large and vigorous, but inky, perspective of Arncliffe Church, Leeds, showing the fine gabled end pierced with two tiers of lancets, exceedingly pure in detail, and excellent in proportion. A partial view of the tower is obtained, but the strength of the design is clearly in the west-end. Mr. Brooks sends in one of his charmingly massive interiors (1,129), simple and pure, but not equal to other works we have seen of his. It is the chancel of the Church of St. Modoc, Scotland. Mr. Geo. Aitchison in 1,128 shows a study in colour; we may call it after the Whistlerian manner, a "Harmony in Black and Grey." We certainly can admire the harmony of colour in the gradation of grey or bluish-green tints, though we think the design too blue and low in scale to please most people. The dado and doors are black, and the wall-papers above pass into light green shades. The work is certainly chaste, and shows refinement. Messrs. Goldie and Child exhibit the interior of a Dominican church, Waterford (1,134). It is an ably-coloured interior of a

Basilican-looking church; the arcades, with their round arches, rest on marble columns, and are good Romanesque; the panelled treatment above arches, and the flat, open-timbered roof, produce a rich effect, though we may question the decorative scheme of colouring. One of the most successful churches is Messrs. Dunn and Hanson's St. Catherine Church, Birmingham (1,147), illustrated by us some time ago. The west end, with its five-light window under an obtuse arch, the treatment of the spire springing from an octagon with pinnacles at the angles, are admirable features, and there is a quiet dignity and repose that is pleasing. The coloured drawing is excellent. Another very fine coloured interior for the Church of the Oratory, Brompton, by Mr. A. J. Adams, must not be passed over. This design has some admirable points, such as the pierced piers, which carry the main ribs of vault, and the screens between them, below, separating the aisle from nave, and the subordination of the latter to the main order employed. But the design is made to appear at its best by the excellent drawing and delicate colouring. The fresco subjects in the ceiling are introduced with remarkable taste and feeling, though we must take exception to the rather large and naturalesque treatment of the figures. Another ecclesiastical work of importance is No. 1,166, a view of the Church of Our Lady and St. Denis at St. Mary Church and St. Mary's Priory, by Messrs. J. A. Hansom and Son. There is a queer want of symmetry in the tower, the angle turret of which destroys all balance, and one belfry window is squeezed in very uncomfortably. The Gothic is of a florid type, and open to the charge of being a little piecemeal in effect. Mr. Brangwyn sends a view of his competitive design for the Yarmouth Town Hall (1,161), a very effectively grouped building in brick, Flemish in feeling and detail, and with a very massive and pleasing tower termination. Close to it we notice Messrs. J. G. Craze and Son exhibit a portion of ceiling decoration at Longleat, in a rather florid style of Louis XV. The colouring is very rich, but heavy. Near it we find another study in an extremely opposite style, Pompeian in character, by Mr. G. E. Fox, in which the questionable feature of pictures is introduced in the panels. No. 1,156 is a frittered and rather confused design for a chimney nook; No. 1,155, design for end of hall, is a far more successful attempt at decoration by Mr. Christopher Gill. A conspicuous place is given to W. Vernon's Buildings, Hastings (1,169), the only remark we can pass being that the drawing is better than the design, which is conceived in a heavy kind of muscular Gothic; while Founders' Hall, St. Swithin's Lane (1,183), is a design in Classic dress of too unmitigated meagreness to enlist the attention of those who have an eye to the picturesque.

* * In noticing Mr. Street's drawing of St. Peter's Church, Bournemouth, last week, by some error, for which we cannot account, we described it as one of its author's "smaller brick churches." The building is really a stone one, and of considerable size, as our readers will see when the illustration appears in our pages.

ARCHITECTURAL ASSOCIATION.

THE fortnightly meetings of the Association were resumed on Friday evening, the President, Mr. H. L. Florence, in the chair. The earlier part of the meeting was made special to consider the proposed alteration of the rules with reference to the nomination of, balloting for, and election of candidates for membership. Mr. Hayes, senior-hon. sec., read the proceedings and reports of the sub-committee which has considered the question. The amendments of rules recommended by the committee were agreed to without a dissentient voice being raised. They

are in Rule 10, in which it has been decided to insert after "proposal of two members," the words "and also of rejecting any proposal"; to omit the words "every nomination shall be made at a general meeting," and to substitute for them "the nomination shall be made at the first general meeting in each month;" to omit the last two words in the Rule, and to add "in any particular case, if demanded at a general meeting, or by letter addressed to the hon. secretaries. In this case the election to be postponed for at least a fortnight, and notice to be given at a general meeting and sent to the proposer and seconder by the hon. secretaries at least a week before the election." A new form for the nomination of candidates was also laid before the meeting, and adopted unanimously. The ordinary business was then proceeded with. Messrs. John S. Nanson and Alexander Whitelaw were elected as members. On the motion of Mr. Hayes a vote of thanks was passed to Mr. Penrose for accompanying the members in their visit of the previous Saturday to St. Paul's Cathedral. The next visit will take place on Saturday, the 17th inst. (to-morrow), to the new Holborn Infirmary opposite the Archway Tavern at Highgate. The President announced that the water-colour class would soon be recommenced under the guidance of Mr. Sutton Palmer, and names of intending members must be sent in before the 19th inst. At the recent *soirée* the drawings executed by the class during the winter were hung on the walls of the room, and he was surprised and pleased to note the great progress made during this session. The surveying class would also recommence on Saturday. Mr. Hayes announced that on that day fortnight the nomination of officers for the ensuing year would take place. At a later period of the meeting the President mentioned that the Royal Architectural Museum Sketching Club had arranged for a series of out-of-door meetings for the summer months to sketch well-known buildings, to which the subscription would be 5s. annually. The first excursion would be held on the 7th June at Stone Church, Kent, and would be conducted by Mr. M. B. Adams; Mr. Randall Druce was the secretary.

THE MEASURING OF ANCIENT BUILDINGS, WITH SPECIAL REFERENCE TO ST. ALBAN'S ABBEY.

MR. JAMES NEALE, F.S.A., then read the following paper, prefacing it by explaining that he considered the easiest way of suggesting how a building ought to be measured would be to describe the actual instance of St. Alban's Abbey, rather erring on the side of minuteness and precision than giving too general an account. The lecture was illustrated by a series of over eighty plans, sections, and detailed drawings, and photo-lithographs from Mr. Neale's recently published book, of great size, and evidencing great accuracy and skill in execution. The first thing that was wanted in measuring the great Abbey of St. Alban, he said, was a long line carried through the doorways of the great screens. A telescope was used in ranging this line from end to end. The intermediate points and the ends were fixed with much accuracy. As it was impossible in paved floors to fasten up uprights, lumps of clay, forming a kind of candlestick, in which thin laths were fixed, were used at intervals on the paving. Then two other lines exactly parallel to the first line were run from end to end of the aisles. Cords were stretched along portions of the first line: lines were squared off at the ends, and the new lines were ranged. At distances of about 50ft. small crosses were cut in the pavement, so that any part could be (and can be) easily referred to. The next task was to obtain similarly marked lines, running from north to south. Strong whipcord was strained along the first line, and a square about 16ft. long in the arm was used. Seven lines were obtained, working from the west end; these were: No. 1, outside the western front; No. 2, inside the church at the west end; No. 3, on the west side of the rood screen; No. 4, through the transept and tower; No. 5, through the openings of the westernmost bays of the sanctuary next to the tower; No. 6, on the east side of the great altar screen; No. 7, through the public passage which then existed through the ante-chapel, but since closed up. These lines were also permanently marked. These main lines were again very carefully measured later on, so that the extreme dimensions could be given in a tabulated list. For the plan, lengths of the main lines were put down with whipcord, secured to nails in joints, and pieces of the building

were measured systematically and plotted as soon as possible. A large board was covered with paper for the 4th scale plotting, which came out about 6ft. by 2ft. 3in., and the main lines being laid down, the plotted portions were attached in position. A little board could thus be used in any part of the church, and the little plans all put together made up the large plan. Short lines were strained near the wall through-out, so that lengths and offsets could be taken accurately with rods without the use of the square. In consequence of the distance of the return faces of the line it became necessary to use a square—the large one previously mentioned—and another one about 6ft. long in the arm was also kept at hand, so that they might be changed the one for the other as occasion required. When some considerable portion of the plan from the interior was ready to be put together, I thought it desirable to set up testing lines on the exterior, although I did not measure the whole of the exterior at that time. A line was put down from east to west, and certain lines from north to south were carried through openings to join the external base line. The lines and dimensions of the great cloister and stype were fixed by means of these lines and diagonals were run on to them, so as to fix the external wall faces of the aisles, transepts, &c. Diagonal dimensions were taken in considerable numbers, both inside and out, so as to assist in the detection of errors. We have hitherto dealt only with the plan; for the section and elevation, it was of course necessary to fix a datum level before beginning anything. This level was fixed at about 4ft. above the level of the east end of the sanctuary, because it allowed the level to be placed upon the floors there, and did not rise above the heads of the doors in the screens. At a number of points this datum was marked on the walls in a distinctive way, and a long mason's level was used to carry the datum to other positions. Five bays in the church were selected for complete analysis—the Norman bays in the nave and transepts, the Early English bays in the nave and sanctuary, and the Decorated bays in nave. For these detailed measurements, special scaffolds were necessary. The landings of the scaffolds were placed at three levels—the clerestory passage level, the triforium passage level, and the top of the capitals of the ground-story arcades. Small scaffolds erected in these landings were necessary for measuring capitals, arches, and other mouldings; ladders gave access to all the other portions. The centre lines of the piers and bays were carried up by means of a plumb-line, and marked at each string-course. All vertical dimensions were taken on the nearest of the vertical lines. The mouldings were measured in various ways. As parts of the buildings were under restoration, I sometimes succeeded in tracing the profiles from the stones themselves; generally, however, the mouldings were measured by means of the straight-edge and square. When the mouldings had been plotted full size, the profiles could be filled in on the general drawings and details. The jointing of the masonry was measured last of all, when the drawings were otherwise complete; slips of tracings were taken off and laid on the small boards carried up to the scaffold, and the joints laid down directly in front of the work itself. The board on which a detail drawing was fixed was hung easel-fashion to the rungs of the ladder by strong clips, so that it could be readily shifted. The small boy, an indispensable and economical assistant, would hold the rule and call out the distances of joints in the masonry, and these could be rapidly plotted with the aid of a small scale and dividers on the board while standing on the ladder. For mouldings, a common pair of dividers was used, the legs being bent inwards so as to span a curve of any form, and cross sections were taken with the aid of these and a rule. For the dimensions, Chesterman's ribbon steel tape 100ft. was used. All the long dimensions were taken twice. It is excellent for the purpose, as it was found not to vary on being tried at intervals by the standard in Trafalgar-square; but it has this disadvantage, that if the unavoidable boy treads on it it snaps. For copying the painted glass, Whatman's drawing-paper was cut to the shape of the tracery, and the main outlines were traced from the glass. The drawing was then completed on the spot. The painted decorations were also traced; for those on the vault of the sanctuary, some 63ft. from the ground, it was necessary to lie down on one's

back on the scaffold, being blocked up as close as possible to the vault. The tracings were made on very transparent French paper, fastened to the boarding with drawing pins. The actual process of measuring having been described the preparation of the drawings ought not to be passed over. The scale of the plan 8ft. to the inch, was followed for the elevations and sections. The detailed bays and the tower were drawn to a scale of 2ft. to an inch, the porches, slype, windows, arcades, &c., to a scale of 1in. to 1ft., and all the mouldings were taken real size. The student will gain immense assistance by associating with and being civil to all the workmen employed on a building. They will then point out various features and give valuable information. Then again, a little beer on a hot-day improves matters and after this, ladders, &c., which were nowhere about immediately turn up. If ever, by the way, I were to undertake such a work again—which I shall not do—I should purchase two or three ladders and sell them when the work was finished. A closing ladder of about 10ft. high is valuable, and easily carried from place to place. Above all things, I know of none I should like to impress upon those students who measure old work more than truthfulness—truthfulness and accuracy in every line and every moulding drawn; no trouble should be spared with even a minor detail; in fact, nothing should be given up with the feeling "Oh, it will do." Every drawing should be laid to scale on the spot. This appears to require time, but will in the end be found the quickest and only reliable manner to obtain accuracy. The system of running from church to church, measuring this arcade and that doorway, and laying the same to scale at a future time, is really the chief cause of the errors we so constantly find. There is no architect, however clever he may think himself, but as soon as he gets home finds one of the chief measurements missing. It is only a short time since I collected eight drawings of a favourite arcade at St. Alban's, made by as many different students, and not one of these was perfectly correct, nor did any two agree one with the other. We are open to criticism from quarters where we least expect it. For instance, some months ago a gentleman finding the scaffolding up in the nave of St. Alban's, had the curiosity to count the number of dog-teeth shown by me in the triforium string; the visit was satisfactory, for he counted 164, the same as in my drawing; but it was inevitable, seeing that they were plotted in on the scaffolding. The young architect should only enter upon the work of publication after serious consideration. He will find numbers of friends advising him to publish. He will even find lithographers temptingly instancing various gentlemen who have undertaken such work, and thereby accumulated little fortunes. All this advice must be taken with caution, and it would be advisable for the intending publisher to consult an architect who has published, and hear his experiences. The quality of line, the openness of the drawing, the amount of reduction, the use of dull ink, of elastic or non-elastic margins, are a few of the things which will force themselves on the attention of the draughtsman, and must be dealt with rightly, and a host of others as well—such as blacked profiles of mouldings, ruled profiles on original drawings, machine-ruled on the first proof of the photo-lithograph, the heraldic methods of indicating colour, and the fearful labour and anxiety of coloured plates—are all pitfalls, obstacles, annoyances, calls for vigilance and good temper, which will fall to the lot of the unfortunate architect who wishes the world to profit by his strenuous labours. I may mention that Mr. Featherstone's new patent ink will be found most valuable for architectural drawing; it has the advantages of being able to be kept in a bottle for years, already mixed, without thickening, it works beautifully for pen-and-ink drawings, and loses the glossy appearance which is detrimental to all drawings intended for photo-lithography. After measuring a large building like St. Alban's, which happens to afford good specimens of work from the Norman onwards, one is supplied with all the materials for comparisons between work of the same scale in the same materials in different periods. Let us, for instance, consider for the moment the subject of proportion. The difference of expression in the various periods is very considerable, although the total height and the spacing differ but little. In a Norman bay of the nave, the pier of the ground story or triforium is as wide as the arch carried by it.

The width of the glass of the clerestory window is only one-fifth of the distance from centre to centre of the bay. In each bay, reckoned from centre to centre of pier, the area of the openings is between one-third and one-fourth of the total area of wall, or, more precisely, .293 of the total area. In the Early English bays on the north side of the nave the great piers of the ground story are less than half as wide as the arches between them. The width of the glass of the two clerestory windows is between one-fourth and one-third of the distance from centre to centre of bay. These windows supply nearly double (Norman 30ft., Early English 54ft.) the amount of lighting found in the bays of the Norman buildings. The Norman windows are the widest, but the Early English ones are higher, and there are two in each bay, instead of only one. In each bay the amount of actual piercing through the wall area is between one-half and one-third (more precisely, .421) of the total wall area, reckoning from floor to plate of roof, and considering the triforium arcades in the light of actual piercing of the wall surface. If these proportions are borne in mind the strong contrast between the work of the 11th and the first half of the 13th century, an interval of from a century to 150 years, will be seen. The architecture has been lightened in every sense. The relation between solid and void has undergone so considerable a change that in place of the somewhat unwieldy dignity of the earlier days, we have graceful, vigorous manhood, full of life and spirit, and with a sufficient dignity of its own. In the Decorated period the proportions are not so widely different from those prevailing in the previous century. If a spectator could abandon for a few moments the habit of questioning about details and would stand in front of the Early English and then before the Decorated bays in the nave of St. Alban's he would find their general expression so similar that he might fancy he was looking at two parts of the same work; the spacing of the bays, dimensions of all piers, sizes of openings, and scale of details are all similar. It is but bare justice to interpose here a mention of the influence of the Norman church on all the work that supplanted it. The height that the Normans gave to their walls, the widths of their bays, the sill levels of their clerestory windows, the impost levels of their ground story arcade are re-echoed in the work of the 13th, and with slight modifications (all improvements be it noted) in the work of the 14th century. The reason why the proportions in the sanctuary differ so widely from those in the nave is an interesting bit of history and the thoughts, doubts, and conclusions of the 13th century builders. The very capable artists who dealt with the sanctuary did not destroy, but completely altered the work they found in existence. They kept it, evidently with great regret, merely because its removal would have imperilled the safety of the central tower. The Perpendicular period is not represented in the structure to the same extent as the three earlier periods. It cannot lay claim either to the very rare excellence and completeness of some of the works of other dates. The abbots commanded skill equal to the best of the time in England, but they directed their efforts merely to the alteration and enrichment of the structure; they were not urged by ambition to destroy and to rebuild, nor to make additions, as their predecessors had done. Thus we find changes constantly going on: massive dignity at the first, then more and more lightening of the masses, grace gained, and wall space parted with. Let us now institute a few comparisons, such as the form of arches. In the original Norman church, consecrated in 1115, all the arches are semicircular. There are in the slype semicircular arches worked to interlace, of the Late Norman period, 1160. Such interlacing arches have received credit for suggesting the form of the pointed arch, but they are not justly entitled to it. The real motive for the use of the pointed arch was a constructive one; in the Early English work at St. Alban's the arches are without exception pointed. The advent of this style was marked, as a general rule, in English by the use of an acutely pointed or "lancet" arch, and, as the style advanced, the extreme pointedness gave way to arches struck with shorter radii. St. Alban's, however, furnishes many exceptions; for instance, the arches in the western porches and in the western bays of the nave are not nearly so acute as some

arches in the eastern part of the church which are more than half a century later. In Perpendicular work the four-centred arch is used, but three-centred and elliptical forms also occur. Again, as to mouldings. Those of the Norman period are almost non-existent in the original structure. Such stone as was used was shaped with the axe, and the varied and delicate forms of later times would not have harmonised with the broad wall-spaces of the Norman builders. When the chisel came into use, moulding, previously out of the question, became possible. In Late Norman work some five forms may be found, but 50 years later 33 independent forms may be distinguished in the Early English bays of the nave. The history of the character of mouldings, in a dozen words, is—1, no undercutting, and then a little; 2, much undercutting; 3, less undercutting; and 4, little or no undercutting. Even to the latest Gothic works, the mouldings are not composed of regular curves, but are drawn by free-hand. By this means is avoided the effect of mechanical harshness, which is one of the crying sins of modern work—professedly following almost slavishly the work of our early masters.

Mr. S. F. CLARKSON moved a vote of thanks to the lecturer for his interesting account of his long labours at St. Alban's. He should have liked to have heard more about the way in which external dimensions were taken, and especially as to the mode in which the internal and external measurements were checked and combined. His peroration had shown very careful study of the different stages of architecture, their qualities and proportions; but he had seemed to attribute to the Norman building too vast an influence over the later structure. To himself it seemed to require considerable use of the imagination to see that the Norman was carried through the Early English bays.

Mr. ASTON WEBB, in seconding the vote of thanks, asked for particulars of the new ink mentioned by Mr. Neale as more suitable for reproduction by photo-lithography, and why it was that the reproductions hung on the walls by the side of the original drawings looked so much darker in line, and if one could sufficiently judge beforehand what would be the effect of a reproduction? Mr. Neale seemed to have given up shading his drawings after a time. Why was this?

The PRESIDENT said the point was forcibly brought home to the mind by Mr. Neale's paper, that before measuring a building it was desirable to sit down and study the best mode of accomplishing the task. The great care the author had taken in commencing his scheme to decide this was remarkable, as well as the courage, order, and skill with which he had carried it out, and the members were indebted to him for re-collecting and recapitulating all the little details which made the paper really valuable.

Mr. NEALE acknowledged the vote of thanks, and briefly replied to the questions which had been put to him. The proportions of the later work at St. Alban's was undoubtedly influenced to a great extent by the Norman building—the height and width of bays were fixed proportions—but builders of each generation regardlessly cut away any of the older work to make for a tomb or fancied improvement. His external levels were taken with the theodolite and frequently checked and compared with the internal measurements by passing lines through the windows. The levels beyond the transepts required an enormous amount of time and labour, and as the President had intimated, the only way by which measuring an edifice could be accomplished was by arranging the general plan of work and its details before going into the building. Of course, as Mr. Aston Webb had said, the total length of the building and other dimensions were about to be altered, but with the present scheme he had nothing to do. The beautiful west porch was to be pulled down to be replaced by better because 19th-Century work, but whether this was to be an imitation of that of the 13th Century, or of the time of Queen Anne, he had not inquired. The ink he had referred to was invented by Mr. Featherstone, of Chertsey. No blue-black ink was suitable for photo-lithography, because all blue tints were simply white in photography. If an ink erred from jet black it should be towards a brown tint. He made at first the mistake of using different coloured inks in the same drawing, but for reproduction by this process the only mode in which tone could be gained was by thickness of line. All lines came out thicker

than drawn. When he commenced work at St. Alban's, Mr. Street looked over the drawings and advised that they should be left unshaded, while the late Mr. Sharpe wished him to hatch them all over, a process which in some of the large drawings would be a work occupying several weeks without adequate results. He found that practically the best plan was to add shading on the stone, by means of a scored roller, which left an impression on all the parts of the stone which had been touched with gum. He should be glad to give further hints on measuring to any one who would call upon him at his office.

THE HISTORY AND AESTHETICS OF ARCHITECTURE.—III.

IN his third lecture, delivered at the Royal Institution on Saturday afternoon last, Mr. Statham dealt with Romanesque architecture. Properly speaking, he said, it was not a "style," but was a process by which the mode of building practised by the Romans was gradually altered by the infusion of Teutonic ideas and influence, and so prepared the way for the development of Gothic architecture. He should devote one afternoon of his course to Romanesque, as one could not properly understand Gothic without following out some of the traces of the course by which it grew out of Roman work. In his lecture last week he had purposely omitted reference to one class of Roman building because its interest was almost entirely confined in its relation to Mediaeval ecclesiastical buildings—the basilica. This was originally a combination of corn exchange and police-court. Illustrations were shown of a restoration in half-section and plan of the basilica of Trajan, from the description of Vitruvius. It consisted of a central area of one floor, and on either side buildings of two stories open to the central portion, and at one end was a high sanctuary and a semicircular recess for the judges' seats. In the basilica which formerly occupied the site of St. Peter's at Rome, the second story had been abolished, and there was a hall with double lean-to aisles, and with a central wall dividing the nave from the spacious narthex and atrium. On the inner faces of the walls, where the roofs rested upon them, the necessarily blank space was ornamented with false windows and bands of ornament; these were the precursors of the very beautiful triforia employed in Mediaeval churches for the same purpose of decorating wall space which could not be pierced or done away with. There were in the later basilicas of Rome indications of a small projecting transept or chamber thrown out to allow of more easy passage to and fro, and adjoining the apse was on either side a passage leading to a circular building. The latter was the link between the round tombs of the Etruscans and the chapter-houses attached to Gothic cathedrals. In many of the later basilicas, especially after they were used for Christian worship, the walls were supported by rows of columns stolen from various temples and other ancient edifices, and introduced with little reference to their suitability the one to the other. A new form of building was seen in the Basilica of Maxentius, built in the days of Constantine, and here the roof was for the first time a series of vaults and sections of domes. The lecturer proceeded to explain in detail what a Gothic vault was, and how it assumed its outlines. The original form of vault was the barrel, but it was found very uneconomical when used on a large scale; the side walls needed to be very thick and massive to withstand the outward thrust, and unless very large stones were used for the crown the component parts did not form wedges but almost unsupported lintels, and hence there was great danger of displacement and sliding. By putting two barrel vaults at right angles across one another, as in the quadripartite vault, the form was strengthened and the points of support were reduced to four. The constructional difficulties were increased where vaults of different span abutted upon each other, as they only could be met with the use of a round arch by the expedient of stilted the smaller arch, or by making a series of small arches cutting into the sides of the principal vault, both of which devices had an unsightly effect in the twisting of the lines of junction. All these and other difficulties were overcome by the use of the pointed arch—a form which was introduced from no ideas of taste or beauty, and certainly not in imitation of an avenue of trees, as popularly supposed, but solely for prac-

tical reasons. It was noticed that a wall need only be thickened where the outward strain of the arch tended to push it over, and the thickening took the form of a pier, and then as the action of strains was investigated that of the Gothic buttress. Having thus explained the development of Gothic features, the lecturer retraced his steps, in order to consider some of the typical forms which Romanesque building took. An early example was the Basilica of San Vitale, at Ravenna, which might be described as a Roman building, with a certain amount of Byzantine detail. It was built after the removal of the seat of empire from Italy to the East, probably during the reign of Justinian or a little later. In plan there was a strong similarity to the central part of the Temple of Minerva Medica at Rome, and to some of the baths, but the capitals of the columns had triangular faces, covered with Byzantine ornament, and were apparently derived from a combination of the coupled columns frequently used for supporting Roman arches. A somewhat similar, but later and rather more clumsily constructed, building, was the Baptistery of Sta. Agnese. These Romanesque buildings seemed analogous to our building churches in colonies with local material, and after the local manner, but sending the stained glass and the decorations from London: and the theory appeared to be confirmed by their character. Another and much more recent class of Romanesque buildings might be grouped together, as showing how this style of building gradually spread over Europe. In these, which were built in the 11th century, there was a central low dome, with other smaller ones grouped around a central hall, and connected with each other by domical vaulting. Foremost amongst these was St. Sophia, Constantinople, the extraordinary and romantic church of St. Mark at Venice, and the central church in the Anjoumois, St. Front at Perigueux. Between Venice, Angoulême, and the East there was a great commercial traffic and constant intercourse, which accounted for the general resemblance between the buildings of countries so widely separated. At St. Front, as, indeed, in very many other of these Transitional buildings, the arches supporting the domical vaulting were pointed, while those used in arcading and for other decorative purposes were round, showing that the pointed form was simply adopted because safer for constructional purposes. The cathedral at Trèves afforded one of the best illustrations of what Romanesque architecture became in the North. The numerous small massive towers ending in conical caps, and the pilasters disposed over the outer faces of the building, were quite characteristic of the style. These pilasters afforded an excuse for thickening a wall where needed, buttresses not having come into use, and the caps were treated after the Classic manner with projecting volutes, but the foliage was changed and made more varied. In the North of Italy the style lasted much longer than elsewhere; the pilaster became still more exaggerated, and took the form, as at San Zenone, Verona, of a series of piers breaking up each face of a building. The style was in Italy treated in a more Classic spirit, and was practised there at the same time that Norman cathedrals were rising in Durham and elsewhere in England. At Valence might be seen a further development of the style and one more nearly approaching Gothic. In this church tall piers supported the arcading, which was still of circular arches, and to the piers were attached columns, which last supported a circular rib carried directly across the vault. The columns had, however, Classic capitals and bases. In the later examples of Romanesque in Northern climates the diagonal arches of the vaulting were frequently bounded by a mere line, but the junction of those which crossed vertically was covered by a flat band of masonry. Of the incipient buttress a late example was shown from Kirkstall, in which it was composed of two pilasters set diagonally, and finished with a square pier or cap. From the same abbey was illustrated the use of the pointed arch for the arcade where strength was needed, and of the round arch for the merely decorative clerestory lights alone. In conclusion, the lecturer explained, by a series of drawings and by black-board illustrations, the gradual development of the Late Norman capital, with its many members and vigorous carvings, from the triangular-headed, foliage-carved capital, adapted by the Romanesque builders from Byzantine models,

and showed how the use of smaller stories, and the improved mode of working, gradually led to the adoption of a lighter and more decorated style.

THE "BUILDING NEWS" DESIGNING CLUB.

A VILLAGE SCHOOL-CHAPEL.

WE have received several designs for this subject, though the requirements have been rather freely interpreted, some of the members having sent in sketches for small churches, while others have lost sight of the character that a mixed building of the kind should possess. "S in circle" again takes the lead. He makes his school and chancel one simple parallelogram, with a class-room projecting on one side, and a small vestry on the other, the lobbies for boys and girls being combined at the end with lavatory arrangement. The conditions required accommodation for 60 children, and the author makes his schoolroom 34ft. by 18ft., with three groups of desks ranged along and lighted on the north side; the chancel is a continuation 13ft. deep, and is provided with a sliding screen which is made to run into a hollow in the vestry wall. The lobbies are conveniently grouped at the west-end and form a double timber-framed porch. The elevations exhibit a Late Gothic treatment, the east-end having a touch of French Flamboyant in its composition, and the class-room making a transept. It is simple in grouping and effective in the detail. "Honey Dew" is a cruciform arrangement, the class-room on one side being made to balance a vestry, organ chamber and porch on the other, with a chancel and sacristy. The fault is that a too church-like plan has been followed, the nave having a central passage and a row of seats on each side. It is not necessary to seat the main building as a nave with permanent seats, as the arrangement shown would not adapt itself for teaching purposes; nor is a pulpit or desk required, nor the choir-like arrangement adopted, as these accessories might be easily improvised when required. The design is unpretending though dignified, in a Late Gothic style, with small tiled turret over east end of nave; the drawing is neatly and carefully executed. "Be to its merits very kind, &c." hits the mark much nearer in plan. The whole building is contained within a rectangle with a chancel apse and vestry at one end, and a porch and cloak-room forming a small projection in the centre of one side. The chapel and school is 29ft. 6in. by 20ft., and accommodates 42 children; it has two groups of desks for seven in each row; at the end of chapel is a class-room of the same width, and 12ft. deep, with two groups of seats to accommodate 24 children. The screen to chancel runs on an iron rail into thickness of wall, the details of which are well shown. We think the plan would have been better if the class-room had been separated by a screen or curtain, so that the whole room could be used on certain occasions. The seats are proposed to be movable, and the author has well studied his details; the external design is suitable, with square-shaped mullioned windows, &c., plain bell gable at one end. The materials are coarse rubble for walls and Bath dressings with red tile roof. The elevations are rather coarse in the hatching. "Jack" sends a clever sketch and plan in a somewhat broken Domesticated style of red brick, the upper part of walls having timber work with concrete filling-in. The school is well lighted by side and gable windows, and is 30ft. by 18ft., entered by two porches at one end; a lobby with lavatories being combined. There is a transept which makes a class-room, a chancel with circular end for altar, a vestry and entrance with recess for harmonium. Sliding doors running into the side chancel wall divide the latter from the school; a prayer-desk and lectern with choir seats are shown in chancel, but no groups to the schoolroom. A quaint belfry, with ventilating louvres, semi-circular on plan, projects over one porch, capped by a conical roof; but the style is certainly a little too grotesque, despite a very good plan. The author estimates his design at £590. "Omega" fails in the planning of his entrance and class-room, which form a small low transept at the end. There is but one entrance to the school-room. The chancel has a rather flat oven-like form, and is not deep enough. Externally the design is better and the style chosen appropriate. The

author proposes to have timbered gables, and a bell-turret at west-end of roof. "Triangle in circle." This is a plain and very suitable treatment externally, but spoilt by an imperfect plan. The class-room does not communicate directly with the schoolroom, and the chancel is rather shallow, though it is spanned by the same roof as the main building, which is a good point in a small structure of this kind. A folding screen is shown between the two. The vestry is an awkward room. The author has conceived his design in a quiet yet dignified manner. "Try" shows a marked improvement in this design, and if he had not such a long and narrow schoolroom, better entrances (there is only one shown), with the omission of the baptistry recess, and a little simpler turret to break the main roof, his design would have stood even better than it does. The plan is based on the right principle of having one main roof and ridge line, but there is no vestry entrance, and the class-room is too small to be of much service. A movable screen is shown. We like the south elevation, and the details are suitable though monumental. The chief fault with "Maggie, alias Sueh a Dog," is the very confused and awkward arrangement of the porch, cloak-rooms and offices, which are made to occupy a large part of the main building instead of projecting. The class-room would have been better in their place. The chancel and vestry are separately roofed. Red brick in a Late Gothic style is proposed, but the centre chimney cropping out in the roof destroys the effect. This should have been placed on one side. "Nitor" is the motto of a design of too monumental an expression. The class-room and lobby are in good relative positions, but the plan is not worked out with sufficient skill, and no seats are shown. Far too church-like is "Impavidum Ferient Ruinae." There is nothing except the class-room to indicate its real purpose; the pointed headed windows and doorways and the deep buttresses are also out of place, and the lobby entrances not so well planned as they might be. The drawing is neat. "Truth shall Prevail," errs on the same side. We cannot see any advantage in the entrance passage on each side of the class-room, nor the lavatory arrangement which forms an extended narthex at the west end. The material is red brick, treated in an ecclesiastical manner, but with detail of a rather coarse and commonplace kind. Drawings are neatly executed. "Noah" sends a pleasing little structure designed in a 17th-century style, proposed to be built of flint and red brick with half-timbered east gable and bell-turret at the west end; the class-room is placed at one end and the chancel at the other, separated by folding doors, so that both may be thrown into one when required—a desirable point. The chancel is surely too low externally. Another design without motto (we believe "Curiose") shows a square-shaped building 24ft. each way, with a hipped roof fitted up as a chapel with three rows of seats. The class-room is at one end and the chancel at the other; but we do not know the use of the scullery with a copper in it unless for tea-meetings. "Con amore" places his chapel at the end of a large class-room 30ft. long, the two being at right angles; lavatory and porch are obtained together in the angle thus formed. The evident result of this arrangement is cost. Why a separate chapel? External treatment is better. The fault committed by "Not wisely but too well" is that of many others—losing sight of the school in the chapel. The class-room is a mere cupboard, and the best part of design is the bell gable. "Melmotte" is too chapel-like, and the class-room is not made the best of. We recommend the author not to try perspective till he quite understands it, and never to draw a canted angle perspective in an elevation, as he has done in the chancel in both elevations where the horizontal lines are shown to vanish. The class and cloak-room in "C. W. D.'s" plan, together with the entrances at both ends, are awkward, and the design lacks study and refinement in detail. "Boz" places his class-room too far from the chapel, and the idea of a school seems to be subordinated to that of a chapel; yet there is something appropriate in the exterior design. "East Anglian" exhibits a suitable treatment; the class-room and vestry and the groups of desk are well placed; the chancel is under the same roof, and a sensible bell-turret surmounts the ridge at the separation, but the entrances are not well-planned. "Steffano" is a rather

expensive plan in the entrances and lavatories, and exhibits a want of skill in combination. Elevations are simple but too commonplace. "Melina" sends a rather more monumental-looking building, Norman in style; but the long wing of cloak-rooms and closet, and the out-of-the-way position of class-room, are objectionable. Why the separating curtain between boys and girls in the chapel? which last is uppermost, if we judge from the seats and fittings. We can only mention "Elève" as a better plan than the last, but expensive in design with a short apse over porch; "Ogmore," too chapel-like in arrangement; "Revus" and "Belteshazzar" both fail in the same way. We may generally sum up the chief defects in the designs as the following: the ecclesiastical arrangements too much, and separately roofing the chancel. Those who have grasped the idea have rather directed attention to the school as the principal element, providing at the same time a spacious chancel and easy means of throwing the class-rooms into the chapel when services were held.

A HALL CHIMNEY CORNER.

WE have not received so many good designs for this subject as we expected. "Noah" sends one of the best and we place it first because it conforms to a current fashion in taste. It is a very pleasing arrangement for a hall recess, opening into the hall by an archway or frontispiece of panelled oak. There is a dog-grate. The details are not fussy, and the seat backs in the recesses are covered with gilt embossed leather. "Ad Valorem" is also a meritorious design in a Gothic treatment. The recess is arched by a deeply-moulded arch, and a series of panels with trefoiled heads relieve the mantelpiece over the fireplace, intended for tile figure subjects. Above this a canopied niche for a timepiece. The details are good. "Curiose" also sends in a Gothic sketch tolerably correct in detail, the fireplace in this instance being placed angle-wise across a canted corner of the hall. The chimney-piece is massively treated, but is spoilt by the final clock-bracket and clock. "Be to its merits, &c.," shows a shallow-arched recess or canted bay with narrow lights in the canted sides. The chimney-piece is plain and has a curvilinear shaped hood of stone. The details are of Perpendicular character. A series of panels in wainscot relieves the space over the arch or recess and the whole is intended to be oak except the mantel and hood. "Yesor No" is a bold sketch in a rather modern Gothic, but the heavy corbels supporting projecting work above the recess, and the ball-flowers to the hollow of it are decidedly *outré*. "Try" sends a clever design in a kind of German or Flemish Gothic. We prefer the recessed treatment, in which some good detail appears, particularly in the chimney piece. It looks like a reproduction or an adaptation of something we have seen before. "Ogmore" does not show plan, and we can hardly make the drawings out. Details are, however, wanting in character and simplicity.

THE WESTMINSTER INDUSTRIAL EXHIBITION.

THE building that has been erected in Victoria-street, Westminster, for the Westminster Industrial Exhibition, to be opened on the 24th instant under the presidency of Prince Leopold, by the Right Honourable the Speaker of the House of Commons, is from the designs of Mr. Seddon, Vice-chairman of the Committee of the Exhibition, and honorary architect.

In the winter holidays of 1877-8 an Industrial Exhibition—by the exertions of the Rev. H. E. Fox, of Christchurch, Westminster, and a committee of working men, and others—was held in the Townsend Schools, lent for the purpose for the space of one week only. The success of that experiment emboldened the committee to try to repeat it on a larger scale, though a proposal which was then made by Mr. Seddon, that a special building should be erected for the purpose on one of the vacant sites in the neighbourhood, was thought Utopian at the time.

In the spring of this year, however, the idea was revived and thought more feasible, and negotiations were entered into with various owners of land in the vicinity, for some time without success. At last, however, a proposal made to the Governors of the Grey Coat Hospital in Westminster, among whom are numbered Canon Farrar and Mr. G. Spottiswoode, met

with a favourable and kindly reception, and a loan of an admirable site in Victoria-street, belonging to the Hospital, was offered until the end of April in this year.

The committee, however, felt that it was impossible to do anything worthy of the object in so short a time, and on their further application the time was extended until the end of June.

This offer the committee resolved to accept, burthened though it was by penalties somewhat awful to contemplate; in case every stick and stone of the erection and its contents were not removed from the site by the day stipulated, the Governors of the Hospital being empowered then and there to enter upon possession and sell everything, and hand the proceeds to the Westminster Hospital.

A public meeting was held in February at the Grosvenor Hall, Piccadilly, to ascertain public feeling with regard to the proposal—the Right Honourable the Speaker in the chair, supported by the Right Hon. W. H. Smith, M.P., Mr. G. Spottiswoode, and Sir Rutherford Alcock, and others. The result of this meeting proving satisfactory, the present committee, with the Rev. H. E. Fox as chairman, undertook the management of the undertaking. Tenders for the building were advertised for, and a spirited offer made by Mr. J. C. Humphreys, of the Borough-road, was unanimously accepted. This was to erect four buildings with timber and corrugated iron, each 70ft. long by 20ft. wide, to remain during the period of the proposed exhibition, for £125, on the condition that, should they be sold within that time, the whole of that sum should be remitted, and the charge should be nothing.

These four buildings were then arranged by Mr. Seddon to be disposed round a space of 70ft. square, and arrangements were entered into with Messrs. Piggott, of 59, Bishopsgate-without, tent-makers, &c., who had sent in another excellent and reasonable proposal as a tender, to cover this interior space with canvas, supported on pillars of timber, arranged in the form of a central nave 30ft. wide and aisles each 20ft. wide, for the sum of about £80. Thus a contract was secured for a building about 110ft. square for a cost of about £200, and possibly only £80, exclusive of what flooring might be determined upon for the central area. Of course, however, large and commodious as such a structure would be for the purpose, much else was requisite. It was the stone, a good sized one, perhaps, of the "stone soup" needed. Fittings, decorations, annexes for refreshments and other purposes have necessarily swelled the total cost to a much larger figure, yet at the same time a moderate one, considering the very large total area that has been covered. On comparison with former undertakings of the kind, the committee have found themselves launched upon a more serious enterprise. The largest number of articles exhibited on any former occasion of the same kind has been about 800. The applications of would-be exhibitors to this exhibition exceed 1,800, so that, considering the eligible locality they had secured, the committee have felt that they were justified in incurring the not inconsiderable risk that they have done. They consider also that they have been most fortunate in meeting with contractors of the liberal and enterprising type of Mr. Humphreys and Messrs. Piggott, who have seen and seized the nature of the opportunity offered to them, and in doing so have furthered the objects of the committee of the Exhibition. Messrs. Verity, of Regent-street, have also undertaken, at almost a nominal cost, sufficient only to cover the labour employed, to light the whole building efficiently and decoratively, with gas, also to lay on water, &c.; and both the gas and water and Queen's insurance companies have dealt liberally with the committee.

Under the circumstances above detailed, the buildings have been erected and completed with such rapidity, under the special sanction of the Metropolitan Board of Works, as temporary buildings only, that they were ready for the reception of exhibits on the date fixed, the 12th instant; and though the Committee have a no slight task before them in the arrangement of the exhibits and adjudication of the prizes, there is fortunately no doubt but that all will be in readiness for the opening on the 24th instant. The two saloons for the refreshment department have, however, yet to be built, and are to be a speciality in their way, being, in fact, two portable billiard rooms, which Mr. Humphreys has undertaken to erect upon the new principle of construction of

wooden and iron buildings, recently patented by Mr. John Taylor, of Birehington, in the Isle of Thanet, and of which Mr. Humphreys has undertaken to become the manufacturer and agent. These being offered for sale, the terms made by Mr. Humphreys with the Committee are of the same character as for the larger buildings, namely, that he is to receive as rent £20 for each, to be remitted altogether if the buildings are sold during the exhibition.

In conclusion, we have but to notice the character of the general decorations, which are not only harmonious but effective. The three parts of the central area have graceful suspended linings to their canvas covering of alternate stripes of crimson and white; and two of the four surrounding buildings have their roofs lined with pale blue, and the other two with pink. The walls will be covered with the exhibits themselves, and the windows with stained glass by other exhibitors, and the tables will be stained and varnished or distempered with colour. A fixed seat has been constructed all round the central area, with exception of part raised at one end as a platform, and steps in the centre of the other sides to descend to the lower level of the central area. 1,500 or 2,000 spectators can thus be accommodated sitting or standing behind and around the central area, in case of opening or closing ceremonies, concerts, or other performances, which will be arranged continuously during the Exhibition by a special committee appointed for the purpose.

A PRIVATE THEATRE AT CHELSEA.

A PRIVATE theatre in a country mansion is unquestionably an advantage where the tastes of the owners lend themselves to such entertainments, and not a few notable residences in England contain more or less complete arrangements of the kind. In some cases the theatre forms the great feature of the house, all the other apartments being made to centre round or lead out of it, with a view to the whole forming one grand suite. This plan is open to some serious objections, among which, of course, are those also common to any contrivance for the housing of a theatre, however small, within the walls of an English gentleman's home. The private theatre now building at Chelsea for Sir Percy F. Shelley, is open to none of these objections, as it is situated in Tite-street, at the rear of the back premises of his mansion, which he erected about a year ago on the Chelsea Embankment. We illustrated the house fully at the time, and a most elaborate and highly-finished residence it is. All the fittings are executed in a costly way from the designs of the architect, Mr. Joseph Peacock. The theatre now building is also from this architect's designs, only, instead of a Gothic style, like the house, a sort of Free Classic or Queen Anne combination has been adopted for the front elevation, which is being carried out in stock brick, with red cut brick dressings enriched in the central feature by stone pilasters and rusticated quoins. The building is to be complete in every respect, having an auditorium of horseshoe form on plan, with boxes on either side and gallery above. The stage has a frontage of about 25ft., and the building stands on a site nearly 70ft. by 60ft., the latter being the width of the front in Tite-street. To the rear a green-room, with painting-rooms and offices, are arranged, including a carpenter's shop, which has an entrance from the next street. The contract for the chief part of the theatre is between six and seven thousand pounds, but ten thousand is said to be the probable outlay before the whole is completed. The builders are Messrs. Lathey Bros., who also built Sir Percy Shelley's mansion above referred to, the drawings of which will be found in the BUILDING NEWS for January 4th and February 1st, 1878.

In the adjoining mansions, erected by Messrs. Gillow from the designs of Mr. E. W. Godwin, we see the workmen are at work making the principal rooms in the big house at the corner more convenient, it having been found that the serious objections found by everyone who saw them quite prevented their sale. The faults were inherent in the original plan, seeing that no really good-sized apartment was provided beyond the billiard-room. This being the case, Messrs. Gillow, at considerable expense, are recasting the interior by throwing the front rooms into one fine apartment, both on the ground and first floors, and, instead of the

recessed bay which occasioned the original sacrifice of room inside, a projecting oriel window is about to be formed, thus adding considerably to the value and convenience of the house. Mr. Adolphus Croft is the architect under whose direction the alterations are being made.

CONICAL ARCHES.

IN a paper by Mr. D. McH. Stauffer, C.E., in the *Proceedings* of the Engineers' Club, Philadelphia, on the South Street Bridge of that city, the author describes some novel points in the eastern approach to the structure. It is the ordinary practice in constructing arches on the curve to widen the piers towards the outer circle of the bridge, leaving the arches "right arches." In the case of the South Street bridge it was thought, and very justly, that the work would be improved in appearance, and a considerable saving in masonry effected by making the piers of the same thickness throughout, and throwing the obliquity into the arches. The roadway was 55ft. wide, and the centre line of the curved portion in which three arches were made was struck with a radius of 169ft. 6in., with an included angle at centre of 33° 25'. The arch abutments therefore formed tangents to the curve on plan. Both of the two piers were 6 course 55ft. long, and had a thickness of 5ft. 6in. and 12ft. high to springing. On the radial lines of the curve the piers were located, their sides being parallel thereto. Each of the three arches had a chord span at the inner end of 22ft. 1in., and at the outer end 32ft. 9in., the rise of arch being 11ft. 4in. throughout, and the crown and springing line being horizontal. Each arch in fact is really a portion of a cone; thus the line of crown of arch would coincide with the oblique side of the cone, while the plane of springing line would be parallel thereto, and cut the axis of cone at the smaller end of the arch. Thus the rise of arch at the smaller end was equal to one-half its chord span. As the crown and springing of the arch were parallel and coincided with slant height of the cone, the ends of arch were not vertical, and had to be cut at right angles to the cone, though the angle made was so nearly a right angle that they were treated as circular arches. The smaller arch was regarded as a full-centred arch, and the larger as a segmental arch. Maine granite was used for the ringstones, and hard burnt bricks for the arch proper. The brick ring was 24in. thick laid in cement mortar, and the bond was arranged so that the thickening of the mortar-joint was confined to the length of one brick, and the bond made to repeat itself in every eight courses. The consequence of the arch being treated at each end differently was of course that a winding skew-back was produced, but in execution the skew-back was made to approximate to this by a series of slight drops or steps every four feet, and enting the face of skewback to suit. This method of construction is at least bold and novel, if not the most artistic mode of dealing with a row of arches in a curved bridge or viaduct; and we recommend to the reader a perusal of Mr. Stauffer's paper, which is illustrated, and enters into details of the centreing employed and the materials used. The result is said to be successful, while the appearance is manifestly better than the old method.

The Cambridge Slade Professor of Fine Art (Mr. Sidney Colvin) announces the subjects and dates of his lectures as follows:—Tuesday (last), "On Some Greek Terra-cotta Figures in the Fitzwilliam Museum"; May 16 (to-day), "On Some Drawings of Old Masters in the Fitzwilliam Museum"; Friday, May 23, "On a Cast of a Statue of Hermes, by Praxiteles, in the Fitzwilliam Museum"; Tuesday, May 27, "On the Engravings of Martin Schöngauer in the Fitzwilliam Museum"; Friday, May 30, "On Some Ancient and Modern Conceptions of Landscape, Illustrated by Pictures in the Fitzwilliam Museum."

It is proposed by Mrs. E. M. Ward to supply a want which has been greatly felt in this country in the shape of a School of Art to which ladies can send their daughters to learn painting and drawing. For this purpose she has obtained the kind co-operation of Mr. P. H. Calderon, R.A., Mr. J. C. Hook, R.A., Mr. W. P. Frith, R.A., Mr. J. C. Horsley, R.A., Mr. J. E. Millais, R.A., and Mr. L. Alma-Tadema, R.A., who have consented to visit the school once a month, thus securing to the pupils an advantage which it would be impossible to obtain elsewhere.

NEW CATHEDRAL AT MELBOURNE.—THE HERTFORD HOSPITAL, PARIS.—NEW BOAT HOUSE, CAIUS COLLEGE, CAMBRIDGE.—WAREHOUSES IN BARTHOLOMEW CLOSE, LONDON.—BILLIARD-ROOM, KILBURN HOUSE.

OUR LITHOGRAPHIC ILLUSTRATIONS.

NEW CATHEDRAL, MELBOURNE.

By the courtesy of the architect, Mr. William Butterfield, we are enabled to give illustrations this week of the proposed cathedral for the Church of England in Melbourne, Australia. It is to be erected of stone in that city, upon a site upon which St. Paul's Church, parsonage, and schools now stand. It is hoped that a hundred thousand pounds, equivalent to about sixty-five thousand pounds in England, may be raised for this purpose. A large portion of a cathedral at Adelaide, Australia, has been already built from Mr. Butterfield's designs, and was consecrated about fifteen months since. In an early number we intend to give some further illustrations of the Melbourne Cathedral, including the sections, so that the principal of the general working drawings of this important building will be placed before our readers.

THE HERTFORD HOSPITAL, PARIS.

A FULL description of this building will be found on p. 549.

CAIUS COLLEGE BOATHOUSE, CAMBRIDGE.

THE boathouse for Caius College Boat Club has been built on the left bank of the river, close to the Ferry. It is built with red brickwork, and the gables are finished with panelled plaster. It is set at an angle to the river in order to bring the boats conveniently down to the landing stage, by this means also a better view of the river is obtained from the windows. The ground-floor is arranged for the stowage of boats. The first floor is divided into two dressing-rooms, one for the first crew, and the larger one for other members, and a balcony is arranged in front where members have a good view of the river. It is being brought into use during the boat races of the present week.

WAREHOUSES, BARTHOLOMEW-CLOSE.

THIS building stands on an area of over 8,000 square feet, and occupies a very open position in Bartholomew-close, replacing three houses which had been converted into a warehouse, but which were found ill-adapted for the purposes of the business, namely, that of a wholesale druggist. In the new building the clerk's offices are placed at the corner by the main entrance on the ground-floor, the private offices being over them, one having a bay window commanding a good view over the Close; at the other extreme of the build-

ing a residence is provided for the head warehouseman. The basement is occupied with oil-cellars, bottle-washing department, engine, boiler-rooms, &c.; the remainder of the floors being occupied by the many various departments required for the business. For the receipt and despatch of goods a double cartway is provided. The principal elevations are executed in red brick, the roofs being tiled. Each floor will have a hydrant served from the high pressure main. A 2-ton steam lift is being fitted up from basements to fourth floor. Mr. Aston Webb is the architect.

BILLIARD-ROOM, KILBURN HOUSE.

WE this week publish an interior view of a billiard-room, erected as an addition to Kilburn House, Kilburn, N.W., the residence of John E. Farmer, Esq. The room is about 30ft. long by 20ft. wide, and 24ft. high to the top of the circular ceiling. It is approached from the old part of the house through a new hall, adjoining which is provided a lavatory for the use of the players. The ceiling is executed in the form shown in pitchpine, the wall and window linings, also the doors and other wood finishings are executed in pitch-pine, all French polished. The chimney-piece is in oak. The table has been made to the architect's special design by Messrs. Burroughes and Waits. The ornamental glass in windows, representing different sports and pastimes, has been executed by Mr. Dixon, of University-street. In addition to the open fireplace fitted with dog stove, hot-water pipes on Perkins' system are fixed behind the skirtings. The whole of the works have been designed by Mr. Rowland Plumbe, F.R.I.B.A., architect, of 13, Fitzroy-square, W., Mr. T. J. Messom, of Twickenham, being the builder.

THE ART OF THE ITALIAN RENAISSANCE.

DR. TODHUNTER on Saturday afternoon delivered the last of his course of lectures on this subject in the New Buildings, Trinity College, Dublin. He commenced by pointing out how the Siennese school of the fifteenth century became merged in the Umbrian school which culminated in Perugino. Vasari stated that Perugino worked for some time with Leonardo and Lorenzo, where he perfected his perspective studies and colour system. He was a very successful painter of the period. Perugia was a city of Mediæval Italy; and Perugino was himself Mediæval. His art was in spirit retrospective. How far he was a religious man seemed doubtful. Vasari said of him he possessed very little religion, and could never be made to believe in the immortality of the soul; that he placed all his hopes in the goods of fortune, and would have undertaken anything for money. There was also a tradition that he died without the rites of the Church, and was denied Christian burial; but that seemed to have been owing to his having died suddenly of the plague, for the monks afterwards had his body transferred to Florence, and honourably buried there. Whether he was a religious man or not he was eminently a religious painter. Mr. Ruskin, indeed, had laid it down that, in order to be a religious painter, one should be a religious man, and deduced Perugino's piety from his pictures. It was, indeed, all but impossible to believe that the man who painted pictures so full of devotional feeling as those of his best period could have been without the feeling thus expressed; but in some of his later works the feeling seemed of a rather artificial kind—sentimentality rather than sentiment. But granting that he was often guilty of the faults of affectation and mannerism, there yet remained in his work a mysterious fascination—an abiding charm—which work that was insincere and mechanical could never produce. His best pictures were steeped in an atmosphere of divine peace, and he was more ethereal and ecstatic than Bellini. He seemed to sigh after an ideal state of serene and holy joy. One remarkable thing in his pictures was the important part which landscape played in the general effect. His landscape, like that of Titian, carried out and emphasised the sentiment of his figures, while it was at the same time clearly Perugian, while that of Titian was Venetian. Perugino's great pupil was Raphael. In Raphael, not merely the Umbrian, but the Florentine school of the sixteenth century culminated. If

a man's originality could be questioned because of his being indebted to others, Raphael was the least original of men. Shakespeare himself was not a more voracious parasite upon the genius of other men than Raphael. As compared with Michael Angelo, Raphael was rather an adapter than a creator, though the former stole something from Signorelli; but Raphael's genius appeared in the magnificent manner in which he dealt with his thefts. He was not a mere adapter, but was a recreator, dealing with the works of other men much as they dealt with the works of nature. It was chiefly as a consummate master of composition that he shone supreme. In other qualities it could not be said that he excelled the men whom he copied. Perugino was very much his superior as a colourist; Michael Angelo's sublimity was altogether out of his reach, and even as a draughtsman Raphael was not always perfect. Raphael's father, Giovanni Sante, of Urbino, was himself a painter of respectable attainments. The lecturer described several of Raphael's principal works, and said the amount of pictures he painted during his short life—for he died at the age of thirty-seven—was simply astounding. The art of the men of the post-Raphaelite, through often technically fine, was essentially debased and decaying. Although Ruskin was in the main right in tracing the decay of Italian religious art to the decay of Italian religious faith, it was nevertheless a fact that the glorious non-religious art of the Renaissance died out *pari passu* with its glorious religious art. The later painters were no less feeble in treating Pagan than Christian subjects.

PICTURE FRAMES.

IN the picture galleries now open to the public, many striking examples of gilt frames are to be seen, and these are well worth the attention of the artist and connoisseur. There is more than is at first sight apparent in a frame. It has not merely to form a setting to the picture; it ought to be in harmony with it. A picture in a low scale of colour is spoiled by a bright gold margin; while for a painting glowing with bright and intense colours, a large gold frame is the best corrective. Some paintings look better in a dull, unburnished gilt frame, others in burnished ones; but the shape, ornament, and moulding have much to do with the effect. For decorative subjects, the common rococo frame of the old style is often completely ruinous, and we contend that the style and sentiment of the painter's work should be considered in the designing of frames. Happily, a few of our leading painters are beginning to look at the matter in this way, and we observe several striking departures from the conventional style of the picture-frame maker. We may draw attention to the frames surrounding Mr. Edwin Long's fine subjects this year in the Royal Academy. His "Esther" (102), and "Vashti" (955), have frames of exceedingly suitable design, and several other very pleasing models may be observed. In the Grosvenor gallery we notice some very admirably designed frames round the pictures of Mr. Whistler. His "Arrangement in brown and black," and "Harmonies in yellow and gold, and green and gold," have a quite unconventionally designed frame, composed of a prominent flat face with projecting edgings of reed-like mouldings, thickly grouped together at the inside where they retire to the picture plane. We certainly see more to admire in the gold frame than in the sensational "Gold Girl" herself. Flat frames with reeded members are also well adapted for architectural drawings, and we notice some good examples of framing in the architectural gallery. Architects know the value of good frames, but artists have not till recently appeared similarly alive to their importance.

Last week the Lytham Commissioners advertised for tenders for some sewerage works—1,634 lineal yards of 24-inch and 21-inch earthenware sewers, the earthenware pipes and manhole-covers to be found by the Commissioners, and all other materials to be provided by the contractor. The highest tender was £1,590, and the lowest £650; only the small difference of £940.

At Waterford Presentment Sessions, on Saturday, compensation to the amount of £1,200, was awarded to Mr. George Walker, builder of the Waterford Convent, which was partially destroyed by fire in January last. The fire was held to be malicious.

THE BUILDING BEGINS MAY 16, 1879.

THE HERTFORD BRITISH HOSPITAL
IN PARIS.

THE illustration we publish to-day of this handsome building is particularly interesting, as illustrating a most carefully designed public institution, and a noble gift by an Englishman to the service of his poor countrymen in a foreign capital. It is very generally known that during the siege of Paris by the German army, Sir Richard Wallace established an "Ambulance Anglaise," of which we need say no more here than that it was greatly appreciated by our neighbours, the French. But at the same time there grew up great need of medical help and aid for the indigent English who remained, and hence in connection with the ambulance, and in premises adjoining a temporary hospital and dispensary was started by Sir Richard. The sufferings of his countrymen during the German siege, and the subsequent siege by the Versailles troops, induced the honourable baronet to determine on founding a permanent hospital where poor people of British nationality might go and have their maladies cured or alleviated by skilful physicians, under the care of trained nurses, of their own country, and where they would be comfortably provided for. From that time, entirely at his own sole charge, such an establishment has been maintained by Sir Richard under the name of the Hertford British Hospital, receiving patients and dispensing medicine and advice free of all charge. After eight years of temporary shelter in a house rented for the purpose in the Route de la Révolte the splendid pile illustrated in our paper to-day has been dedicated as a place of permanent occupation, at a cost, we believe, exceeding £40,000, besides the considerable sum to be set apart for its ample endowment. The foundation-stone of the building was laid by Sir Richard and Lady Wallace on the 24th August, 1877, being the seventh anniversary of the death of the late Marquis of Hertford, to whose memory and in honour of whose generosity it has been built. On the 16th of last month it was formally inaugurated by the honourable baronet and his lady receiving the British Ambassador, Lord Lyons, and several invited guests, when it was dedicated to the exclusive use of British poor persons, and entrusted to the care of a small committee consisting of Sir John Rose Cornack, M.D., the Hon. Alan Herbert, M.D. (the two physicians), and Mons. Levopene, of the Boulevard des Italiens. Contagious or manifest incurable cases are not eligible for admission, but all classes of accidents requiring immediate attention are promptly attended to. The physicians alone decide on suitable cases. The hospital is situated at Levallois Perret, where that village forms a junction with the well-known suburb of Neuilly, five minutes' walk beyond the fortifications. It stands on a rectangular plot of ground of 7,225 square metres, the front opening to the Rue Villiers. Without the least participation on the part of either of the two townships, Sir Richard Wallace built at his own cost more than 3,000 metres of sewers, so as to secure more completely the salubrity of the establishment. An iron railing faces the front entrance, and a large open space forms a carriage way to the central building. To the right and left are extensive gardens. Ascending by three steps we enter a large hall of such considerable dimensions that we are at once struck with the grand scale on which the building has been designed, and these spaciousness and lofty dimensions continue a marked feature throughout. To our right is the porter's lodge, and the fine flight of stairs leading to the men's department; to the left a parlour for the use of the lady-superintendent, and the steps leading to the apartments for women. In the centre, between the two flights of staircases supported by arches, the hall continues on a level of six steps below the entrance. To the right of this is what is called the council chamber, used also for a library. A large opening leads to the aisles and to a sitting-room for unoccupied nurses, from which they can see what is going on in the two consultation rooms. Here, too, is a door which leads to the waiting-rooms for out-door patients, which are entered also by doors from the garden. Both these waiting-rooms are in communication with the pharmacy and consulting room, and each has an enclosed portion for patients whose cases require them to remove

their clothes. The two openings facing the entrance lead to the northern aisles. In the centre are stairs connecting all the floors with that portion of the building, and an elevator is fixed just opposite, available either for the lifting up of patients or other purposes. To the right a room for general purposes, and at the extremity the well-arranged and appointed kitchen, touching the building only on one side. To the left is a capacious larder and scullery, and further on we come to the hydropathic department, most expensively and completely furnished with baths of all kinds, established more especially for the use of out-patients, and this building has an entrance from the garden, so that such bathers enter without passing through the main building. Returning to the entrance hall, we find a plain but commodious chapel on the left, opposite the council-room; then, ascending to the right, we penetrate the apartments for men, entering the large hall, or chief ward, through a small ante-chamber giving access also to a small nursery-room in which are two side closets, with a supply of hot and cold water, a linen cupboard, and a bed, occupied by a nurse, who, by means of a small window, can at any hour of the night glance through the chief ward, which has twelve beds, two of which are designed for children. This ward is of the height of two stories, and three bays of joists divide the vaulted ceiling. In each bay, at the height of the eye, a window affords the patients a view of the surrounding country; above a band, running more than two metres from the floor, are two coupled ogival windows, crowned with a *rosare*, allowing light freely into each bay. The ventilation of the chamber is well provided for, and the physician has it in his own control. The extremity of the room is finished off by a large, open fireplace, with a faience trimming, where drinks may be kept warm. On each side of the fireplace are three ogival openings, one of which forms a door leading to a stairway connecting the ward with the garden. Under each window is a small opening for the introduction of draughts when desired, and between each bay are ventilators, put in motion by a gas-burner, hid by day by stained glass windows, and which at night are used as night-lamps. The ward (as well as every part of the building) is heated by hot-water tubes, covered with a grating. Returning to the landing, we find adjoining a reserved ward for special cases requiring isolation or special attention, and this is at present fitted with three beds, in a space, however, in which not uncommonly twice that number are placed. A door leads out of this room on to a terrace. Passing by other bath-rooms, water-closets, &c., we proceed to the section for women, which in all its arrangements is precisely the same as the men's. It should be stated, however, here that the staircase in the centre is well lit from the top and well ventilated. Opposite the entrance on the first floor are rooms for patients who may have to undergo operations, with an ante-room for a nurse, and these also have access to a separate balcony. The apartments of the house-surgeon and the lady-superintendent are spacious and commodious, and are so arranged that they can each have under their inspection at any moment the separate departments. On the upper floor are comfortable rooms for nurses and servants, and linen-rooms well stocked with every article of clothing, for patients here all wear a wardrobe provided for them by the establishment, and there is here also a bath-room for the special use of the servants. An electric clock gives the time in all parts of the hospital, and a public clock, which is provided with means for night lighting, is fixed in the roof. It is hardly necessary to say that the operating-room, and in fact, every department, is fitted with the most approved appliances for the use of the operator and the convenience of the patient. There is no paint used in the building; all the wood is varnished pitch-pine. From the northern aisle, and communicating with the court by two stairways, is a large avenue closed with two railings, leading to a mortuary, which besides an apartment for the dead has also an autopsy room, a room for the reception of dirty linen (which is sent out for washing), a room for the public and for prayer before the removal of a corpse. A small enclosed court separates this building from the public thoroughfare, into which access is gained in the Rue Chaptal. The architect is Mons. Sanson, of the Rue d'Anjou St. Honore, Paris.

THE PRESENT ART REVIVAL.

At a meeting of the Edinburgh Architectural Association, held on the 7th May, a paper, entitled "Notes on the Present Art Revival," was read by Mr. Thomas Bonnar. He began by alluding to the practical tendency prevalent at the present time, by which it is attempted to gauge and define that most subtle and æsthetic of subjects, "artistic taste." Deprecating these efforts, he went on to refer to the great advantages possessed by our Continental neighbours in the ready access they have to the innumerable authorities and examples they are encouraged to study, while we, as a nation, are still struggling with the many difficulties which must be overcome before attaining a high artistic position.

To the inattention and indifference to artistic matters which frequently assume the shape of wilful neglect might be attributed much of the ignorance of the real constituents of art which prevailed; but this is now being remedied, and the principles which govern the true expression of art in pictorial, architectural, and domestic application are receiving that study which they so deservedly merit, as well as obtaining from the public a high appreciation of its qualifications.

The Free Classic, or Queen Anne, style was commended in preference to the Gothic, from its more appropriate character, and the facility with which it could be adapted to the interior embellishment of the most stately, as to the most unpretentious, of buildings; besides the advantages which it possesses of affording a medium for the artistic use of colour in decoration and furniture, while guarding against the indiscriminate employment of false and meretricious details.

The examples of British art manufactures in the Paris Exhibition were also referred to as exemplifying the progress which art culture was making in this country in the design and excellence of execution which the furniture and textile fabrics displayed; by their high standard in these essentials challenging the claim for pre-eminence in artistic productions which has hitherto been allowed without dispute to our Continental friends, and proving that the English were capable of originating, and successfully carrying out, a style peculiarly their own, which it would be difficult indeed to surpass for originality of thought and artistic workmanship.

A strong argument in favour of the artistic use of colour in our rooms was advanced, and in reference to this point, Mr. Bonnar observed, "that it had been put forward as an objection, that in the style spoken of there is an obvious tendency to gloomy effects, which are often mistakenly, if not indeed ignorantly, employed for the purpose of obtaining what is supposed to be pictorial interior treatment. Doubtless the use of colourless mediums may be deemed a safe resource, where there is lacking the knowledge of the correct treatment in combination, of the primary and tertiary tones of colour, and the perception of being competent to apply them with their respective complementary shades, and keeping them in due subjection in their constructive relation and fitness to the subject treated."

"It is only through this knowledge and correct perception that full tones of colour can be brought into true position as an appliance for obtaining richness and harmony, and bestowing a furnished aspect to a room. By this means masses of colour that would, if taken by themselves, promote a feeling of harshness even to crudeness from their incomplete operation, are controlled and moulded, as it were, to lend form and richness which can only be arrived at by strict attention to their ulterior purpose, always, however, having in view the textile and other accessories which go to make up the complement of an appropriately-furnished apartment."

By this means it was argued the taste and ingenuity of both the artist and his client could be displayed, and made to result in a pleasant and harmonious combination of the truest decorative principles, in place of the lately-prevailing tendency to colourless mediums.

The art revival was making steady and sure progress in public estimation, and all true friends of art in this expression of one of its highest functions were urged to do their utmost in promoting its success. The paper was illustrated by coloured drawings.

The Chippenham local board have approved plans and specifications, prepared by their surveyor, for proposed baths.

NOTES FROM EDINBURGH.

THE long and severe winter of 1878-79 has swallowed up the spring. A sprinkling of snow in place of dew on the morning of the 1st gave notice of its intention to "linger in the lap of May;" and though the summer sunshine has come at last, it has to rid us yet of such unpleasant reminders of the past as the North wind and showers of hail. Building operations, after being completely suspended for four months, were resumed about a month ago, mainly in the way of alterations in the streets and resumption of the larger works in progress. A few new villas of the better sort are rising in the southern suburbs, and the demand—if there be any—is for the larger and not the smaller villa of the better kind. The letting season has passed, and great numbers of the latter remain untenanted, and cannot find a purchaser. There is not, however, a complete collapse of building speculation, and one scheme of this kind has been getting notoriety of late by its proposal to convert the finely-wooded demesne of Warriston, or that part of it next Inverleith-row, into a range of lofty tenements and shops. The approach to the city by this thoroughfare has hitherto had much of a country aspect, running between the Botanic Garden ground and nurseries for a great portion of its length. The trees on the Warriston boundary are very fine specimens of their kind, and have long given their grateful shelter to the footpath, and will be sorely missed. It says very little for the taste, and not much for the ingenuity, of the parties concerned in the proposal if they cannot devise a method of utilising the ground without so great a sacrifice. The thoroughfare in Princes-street and the footpath next the gardens are being rapidly completed. The latter is a cement pavement, called granitic, because the concrete of the top is composed of pounded granite of the size of gravel turned out of the stone crusher. This concrete is laid over another bed of cinders and broken brick, also of the size of gravel, and the whole, after being pretty thickly dusted with the pure cement and levelled with the trowel, is rolled with an iron roller leaving minute indentations on the surface. This pavement, a portion of which was laid down before the frost, has stood the severe test of the winter, and promises to be the pavement of the future. It is laid down in sections 12ft. square. There is not much probability of its being injuriously affected by heat or rain—and if this be found to be the case—it will probably surpass in durability the rival Val de Travers. This pavement shows already symptoms of disintegration on the North Bridge footway, and on the side most exposed to the heat. The surface has lost considerably the original level, and great holes are appearing. This result is not to be found in the Leith Kirkgate, where the sun has not access in the same degree. But very possibly the design of the North Bridge has not made allowance for the expansion of its vast amount of metal. In the Waverley Iron Bridge the pavement (which is stone), is raised in very hot weather, and is cracked from end to end, and this may have somewhat to do with the disturbance of the asphalt.

The work of restoration is going on in St. Giles's Collegiate Church, but has not resulted in any interesting architectural discoveries, except indicating the methods adopted by the last restorer to convert the stone pillars and capitals into plaster shams. Dr. W. Chambers, who distinguished himself at a very early period by his antiquarian researches and discoveries in the Old Town, has undertaken the present work of restoring the south transept and its aisles at his own charges; but he has also offered to complete the work, and open up the whole edifice on condition of this offer being accepted by the Council and Presbytery before May, 1880. This involves the vacating of West St. Giles, or the nave, by the congregation now holding possession of it as a church; and it is understood that no obstacle is in the way but the difficulty of raising funds for the erection of another church.

The University Extension buildings begin to make some appearance over the enclosures, and the spire of St. Mary's Cathedral is making rapid progress to completion. It has reached the height of rather more than 200ft., and may possibly be finished at its present rate of progress in less than two months. The library has

been roofed, and the vaulting of the choir is going on. The unfinished condition of the corridor exit at the chapter-house is a great disfigurement, and the sooner this part of the design is proceeded with the better so far as the Melville-street front is concerned.

The nave has been opened for service for some months, and under the most unpropitious circumstances as to weather. The powerful heating apparatus was not always successful, nor could it be with such perpetual frost and the east wind piercing the canvas protection at the tower. The heated air is admitted at a grating on the north side of the west porch, and there is always more or less of a gale in this quarter. The heating apparatus for the choir is separate, and placed in a vaulted chamber beneath the library. The church furniture for clergy and choir is plain and simple as befits the temporary character of the present arrangements. A very fine organ, sweet-toned and powerful, is fitted up under the bay of the north aisle, next the tower, but forms no part of the cathedral organ which is being built.

The accommodation for the congregation is for upwards of 1,000. The chairs are ranged on either side of the centre and aisle passages, and are very much superior, so far as comfort and convenience in kneeling are concerned, to the best pews as usually constructed. They are, however, more prodigal of space than economical arrangements would allow. Seats are free, but a portion reserved for the regular congregation till the bell has rung. In the evening there are none reserved even in this way, and the whole nave is generally filled. The aspect of the interior, being wholly devoid of plaster decoration, and almost entirely, except in doors and roofs, without the usual amount of fixed woodwork, is something so different from church architecture in general, and the vast surface of polished and chiselled stone work, with the rough rubble in the aisles, looks so cold, that one at first almost regrets the absence of plaster and brick, and wood lining. In a little while, however, and the illusion is dispelled, and the most sceptical will allow that his position is as comfortable as it could be in a cushioned, closed, or curtained pew.

The interior is lighted by 12 coronae of 36 lights, suspended from a bracket in the clerestory, one opposite the centre of each of the six arches of the nave. An arm and cluster of lights project from each circular segment of the ring, and all in the neighbourhood of the lights is silver-work and brass of very ornate and elegant design.

The acoustics of the edifice are wonderfully good, considering the absence of most of the conditions considered necessary by parties who are prone to theorise upon the subject. There is no resonant material but only in the roof. The interior is very long in proportion to the breadth of the nave, and very lofty. Taking observations at the western extremity, it will be found that the words of the clergyman reading the service from the north side next the pulpit are most distinctly heard without any echo or disturbing influences to mar the compact utterance of the syllables. The conditions will be greatly altered when the screen has been removed and the choir opened up behind the voices. The varying results produced at present by the various parties officiating in the nave, and their different positions, forces upon one the conviction that a great deal depends upon the speaker and his way of speaking. This much may be said of the cathedral, that its acoustic properties at present are better than those of the other two large interiors of the same size in Edinburgh, viz., the Church of the Jesuit Fathers in Lauriston, and the new Catholic Apostolic Church. Both these buildings have one large auditorium without aisles. In both these is a sanctuary. In the latter, the effect of the reflection of sound from the unbroken surfaces of the walls is very curious at times, and at a little distance from the speaker, when he comes to the front step of the sanctuary to read his homily, the trumpet gives a most uncertain sound, and by accident, if not design, he speaks in what is, to all appearances, an unknown tongue. This unfortunate result is evidently occasioned by the absence of aisle and arching to break up the waves of sound on the reflector; on the other hand, though much further off, the voice of the intoning from the altar is comparatively, though not quite, distinctly heard.

ART FURNITURE.*

MR. A. JONQUET'S "Original Sketches for Art Furniture" in the prevailing styles—the Jacobean, Queen Anne, and the Adams—will be found of service when so much that is bad and indifferent in reproduction is foisted upon a too credulous public as antique. Lately there has been a rush for Jacobean furniture and that purporting to be after Chippendale and the Brothers Adam, and a number of imitations have been produced at high prices, though without any guarantee that they have been honestly constructed. Ordinary buyers know little and care less about the actual design of these articles, which are in most cases utterly bad and inferior imitations, and Mr. Jonquet's book of sketches will be found useful by both classes, the manufacturer and the purchaser, especially in the styles last mentioned. There has been amongst one section of the public a reversion from the heavier style of the Jacobean to the finer and more delicate construction of the Classic revival which was the fashion during the reigns of the earlier Georges, and was promoted by the Adams Brothers and Chippendale, and probably by the taste of the Court of Louis XV. There seems to be a desire to avoid the extremes of the Stuart, and the frivolous ornamentation of the French. In glancing over the book of Mr. Jonquet we notice a few designs of a rather hackneyed character. The first sideboard is faultless in general proportions, and the character of the lower framing good of its kind, but the cove looks very heavy, and it is a feature that is likely to become in the hands of many a little used up. We, however, prefer this treatment to the second example given, where the centre part has upright framing and the cove at the ends gives a somewhat disconnected and broken look. No. 3 is a trifle over-fanciful in the lower panelling. Infinitely better are the small sideboards, and we note especially with commendation plates of 8 and 9. The dinner waggon and couch are exceedingly quiet and chaste. The Chippendale chairs also please us by their extreme simplicity and avoidance of undesirable ornamentation, and the artist appears to have caught the spirit of the original style. Though unique, the chimney-pieces are not so good in the Adams style as they might be, and the author has certainly failed in selecting his models. The sketch showing Wedgwood panels in the last example is unhappy; the arched mouldings under mantelshelf are destructive to the repose of the whole composition, and subverts the architectural meaning. We have seldom seen tasteful or sensible designs for hatstands. The one given, purporting to be in the Queen Anne style, does not strike us as very characteristic, though this we do not complain of so much as a rather purposeless design, and the badly shaped pegs for the hats. The other designs for hall furniture are very nice, and the hall benches especially so, in which the backs and arms are relieved by the simplest scallop or shell pattern. The bookcase in the style of Adams has the fault of being too much ornamented in the cupboard doors. Passing over several other designs for panels, finger-plates, and a pier glass, the latter a weak and rather nondescript suggestion, for one more Japanese in its motif, we come to a variety of designs for cabinets and wall cupboards, some very pleasing and appropriate. The "bric-a-bracs" are suggestive, but the best cabinets, to our taste, are those having a hollow centre in plan, the cupboards forming outside projections with shelves for bric-a-brac, as shown in one of the design. The oval mantels are not so happy. The "Adams mirror" is chaste; and a few very pleasing designs for tables and bedroom furniture in the last style close the work.

Throughout the designs we notice the detail is shirked, the mouldings being drawn with a certain want of precision that is unpleasant. In a book of a suggestive kind like that of Mr. A. Jonquet's this is perhaps not a great fault, yet a little more decision would have made the sketches more welcome. If sketch plans had accompanied some of the designs the book would have possessed more practical value, and we think the author might with advantage have been a little less sparing of litho and descriptive letterpress, of which there is nothing. In the next edition, too, we recommend that the plates be numbered if only for easier reference. With these sugges-

* Original Sketches for Art Furniture, in the Jacobean and other styles. By A. JONQUET. London: B. T. Batsford, 11, High Holborn.

tions we are prepared to recommend Mr. Jonque's sketches to those who prefer the lighter and more modern styles of artistic furniture.

ARCHÆOLOGICAL.

BELCOE.—During the formation of a line of railway between Enniskillen and Sligo, a mound has been dug up on at Belcoe, Co. Fermanagh, which was considered, in accordance with Hibernian custom, to be a trace of Cromwell's battlefields. Last week, however, Mr. Wakeman, the local hon. secretary of the Royal Historical and Archeological Association of Ireland, examined the spot, and pronounced it to be a tumulus of the most primitive type. The central work, which is perfectly circular in plan, measures 125ft. in diameter. Its height is 12ft. 9in. It is further encircled by a fosse and ditch. All over the mound entire skeletons *in situ* and broken portions of the human frame were abundantly found. Amongst the *débris* a quantity of wood charcoal was evident, and flakes of the same material occurred more or less all over the mound to a depth of several feet. Not one article of metal has been found excepting, nearly upon the surface, a silver penny of King John struck in Dublin, exhibiting, as usual, the triangle, star, and crescent, but the sepulchre afforded some specimens of stone globes. Such remains are generally supposed to have been symbols of the sun or moon. The larger measures 19in. in circumference; the smaller is about the size of a musket ball. A small portion of a vessel of hard-baked clay, possibly a food holder, or burial urn, was also found. Some of the skulls had fortunately been preserved. Mr. James Plews, manager of the line, has promised that any further discoveries shall be carefully recorded. The local engineer, Mr. Logan, has also co-operated in the investigation.

A ROMANO-BRITISH TOMB.—A few days since a very remarkable discovery was made on the estate of Mr. George Palmer, M.P., at Eling, in the parish of Hampstead Norris, near Newbury. During the course of excavating for field drainage, the workmen struck upon an arched vault or grave, which has been pronounced by Mr. W. Money, F.S.A., of Newbury, to be a Romano-British sepulchral chamber. The tomb lies north-east and south-west, and gives an inside measurement of 8ft. in length by 2ft. in breadth, the height of the roof from the floor to the ridge being about 4ft. The walls, which are built of rough flint with bonding courses of brick, are 2ft. high, and as perfect as when they were first raised. From the walls spring an arched, peaked roof or cover, formed of the well-known flanged Roman roof tiles overlapping each other, and set in mortar. Within this the internment took place. The floor of the chamber was on a bed of gravel, over which had been spread a layer of clay, and on this appeared to have been cast the remains of a funeral pile, consisting of wood ashes, with fragments of human bones and a few nails, which may have fallen from the tiles above. It is possible that the dead body had been burnt on the spot where it was buried. In clearing out the grave, which unfortunately had been effected before Mr. Money's attention was called to the discovery, a metal ring, now in the possession of Mrs. Palmer and of which no information has yet been obtained, was found. Part of a small sepulchral urn, of a black colour, known as Upchurch ware, was also thrown out of the grave; but no coins or personal ornaments except the ring were noticed, nor has any inscription or impression been observed on any portion of the tiles or other materials. This tomb is in the immediate neighbourhood of a Roman villa which was discovered some years since, but has never been properly explored. It occupies an area of about 60ft. by 45ft. A considerable portion of the walls and the tessellated pavements, of common red brick tesserae, still exist, though much mutilated by the use of the steam plough over the site. Among the ruins can be seen quantities of roofing-tiles and scored paving, stucco or wall plaster, painted or dark-red fragments of pottery, oyster-shells, animal bones, &c. From the fact that the tomb evidently belonged to a person of some rank in society, and that in the country the owner of a villa had his burial-place in his own precincts, it may be fairly conjectured that this grave was occupied by a denizen of the neighbouring dwelling. Another Roman villa was discovered some few years ago on the adjoining estate of Mr.

H. M. Bunbury, of Marlstone House, and, according to Dr. Stukeley, a Roman altar, dedicated to Jupiter, was dug up in the adjacent parish of Frlsham in 1730.

SCHOOLS OF ART.

SHEFFIELD SCHOOL OF ART.—ANNUAL RE-UNION.—Last Friday evening the third reunion of the present and past students of the Sheffield School of Art was held. Mr. M. E. Hadfield, the president, said that of the fine arts he perhaps knew most about architecture. In England architecture was usually divided into three heads—civil, military, and naval. He proposed to say a few words on the first only. The historical part of the subject presented a wide field for research. Whether they ascended the Nile, and contemplated the grand and solemn monuments left by the Egyptians; or whether they visited the wonderful caves of Ellora and Elephanta, and the remains of Hindoo or Assyrian architecture they should at once be stimulated to trace the origin of glorious architecture from its very cradle. He referred to Cleopatra's Needle as attesting the wonderful power of the Egyptians in portraying and recording the history of their country in language perhaps difficult in our day to decipher, but yet as complete and enduring as any record could be. He passed on to Greece—that classic land the inhabitants of which cultivated and excelled in literature and art—and afterwards to Imperial Rome, where they discovered a large and constantly varying development of pure Greek art, wonderful indeed for its colossal grandeur and profusion, but in his judgment lacking the purity and simplicity which lent such a charm to Greek art. Having alluded to Byzantine art, which arose from the ashes of Imperial Rome, he went on to speak of the architecture called Gothic by the superficial and conceited observer. The name was originally given in derision, but he felt that English excellence in art owed very much to the grand old cathedrals and churches, which, great in decay, still told in language not to be mistaken that there were giants in those days. To attain anything like excellence in the practice of Gothic art it was necessary that the student, satchel and sketch-book in hand, should visit the old churches and castles in this land. In his younger days he had spent week after week in this kind of work, and he would much advise students in order to obtain knowledge of the principles of this style of art to follow his example. He did not intend to allude to the architecture of our own time, for diverse opinions, captious criticisms, and vulgar prejudices interfered with a calm review of what had been of late and was now being done. It would be for those who came after to judge if the English architects of the present time had degenerated, or rather if they had made the most of the opportunities presented. He would urge his young friends, whilst not despising any style, to practise none, unless they had at least mastered the rudiments. He cautioned them against being too easily satisfied with what they did. Nothing was so fatal to the real progress of a young and promising student.

COMPETITIONS.

GREENOCK MUNICIPAL BUILDINGS.—The representatives of the Press were permitted to view this collection of competitive plans last week. These are well hung for exhibition in the picture saloon of the Town Hall, and embrace about 50 designs, sent from all parts of the United Kingdom. Among the leading may be mentioned those marked with the mottoes "Argosy," which has elevations well treated in the first style of art, "Hope," "Business," a design of great merit with an admirably arranged plan, "Municipal," and "Renaissance." Many of them are remarkable for their mottoes, as well as for peculiarities in planning and treatment of the elevations. One competitor has been odd enough to adopt a sealing wafer, while another has a diagram of the rising sun. Among those remarkable for peculiarities of plan may be mentioned "Art and Science," which has a large tower close up to the building line of an exceedingly high building presently existing. This design, which is very elaborate, and a few others, would cost double the sum mentioned in the instructions to architects. Several of the competitors show considerable skill in planning, but

very few express the purpose of the building by their elevations. Many of these are highly ornate, and all styles of architecture are represented.

ISWICH.—We believe that Mr. Charles Barry is to receive sixty guineas and his expenses for reporting on the plans for the new post-office. One of the Town Council thought somebody might have been got at a lower figure. The Mayor—whether the wish was father to the thought or not we cannot say—said it was *just possible* the referee might report that none of the plans had complied with the conditions, in which case of course the town would save the fifty guineas premium offered.

RAMSGATE.—At the meeting of the Improvement Commissioners on Tuesday week a letter was read from Mr. W. G. Osborne, a competitor in regard to the designs for the new road, protesting "against the payment of the premiums of 200 and 50 to the makers of the plans placed first and third by the adjudicators," as those plans were not designs. It was resolved to ask for a written report from Mr. Abernethy on the subject of the new road, and his views on certain plans.

SAFFRON WALDEN GRAMMAR SCHOOL.—For the erection of new grammar schools to be erected in Ashdown-road four sets of plans were sent in under mottoes. These have been examined by the governors, who selected one, the author of which subsequently proved to be Mr. Burgess, the architect of the town hall recently erected in Saffron Walden. The adopted plans provide schoolroom and classrooms, with accommodation for 25 boarders and 100 day-scholars, with sick-room and headmaster's dwelling-house. The works will be commenced in the autumn.

PARLIAMENTARY NOTES.

THE METROPOLITAN BRIDGES.—Sir J. Lawrance wished to know on Monday from the Chairman of the Metropolitan Board of Works when the remaining toll bridges over the Thames would be thrown open free to the public. Sir J. McGarel-Hogg said there was no authority for the statement which had appeared in the public prints that five additional bridges would be thrown open on the 17th inst. The second section of five bridges would, however, be opened within three weeks. He could not at present fix the precise day. There were beyond that number three bridges which would remain to be thrown open.

CHIPS.

There are in Ireland no less than 155,675 mud cabins, not one of which contains more than one apartment. These 155,675 cabins are occupied by 227,379 families. There are, however, 357,126 mud cabins of the better class, which afford accommodation for 432,774 families.

The Luton Rural Sanitary Authority have decided to consult Mr. W. R. Phillips, C.E., as to the best means of furnishing a water supply for the village of Stopford, and have authorised a committee to obtain tenders for the execution of the same.

The memorial stone of a new Wesleyan Chapel, was laid at Stechford last week. The chapel will be a red-brick structure, with stone facings, and will seat about 350 persons. The architect is Mr. George Ingall, and the builder, Mr. Lee, of Ashton-road, Birmingham. The cost will be about £1,500.

The south aisle and porch of the parish church of Uleby, Lincolnshire, have been rebuilt under the direction of Mr. James Fowler, architect, of Louth. Messrs. Potts and Blanchard, were the builders.

The village of Whiteabbey, Belfast, has been practically rebuilt by Messrs. J. Lowry and Sons, under the direction of Mr. John Lanyon, architect for the Whiteabbey Spinning Co., whose works are adjacent.

New baths and washhouses have just been erected at Belfast. The plans were prepared by Mr. William Hastings, architect, Mr. W. B. McMaster being the builder. The buildings are of brick, with stone dressings and terra-cotta bands. The structure will cost about £4,000.

An exhibition of gas apparatus similar to those which have recently been held in Leeds, Bradford, Halifax, and other places, was formally opened on Monday in the saloon of the Corn Exchange, Wakefield.

At Poulton-le-Sands on Thursday afternoon in last week, William Harper, contractor, of Liverpool, committed suicide by hanging whilst in an unsound state of mind.

Building Intelligence.

ARNOLD (NEAR NOTTINGHAM) CEMETERY CHAPEL.—A lodge and entrance gates have just been completed at above village. The chapels are attached with a tower and spire, vestries, and porches. The lodge is a one-story building, with board room. The entrance gates have stone pillars and wrought-iron gates. The roofs of the chapels are open-timbered, covered with tiles. All the buildings are of Bulwell stone, with Bath stone dressings. The spire is 90ft. high. The works were executed by Mr. William Shipstone, of Nottingham, at a cost of £1,893, from the designs and under the superintendence of Mr. Robert C. Clarke, architect, Journal Chambers, Nottingham.

BREWOOD.—The Parish Church of St. Mary the Virgin was reopened on Tuesday week after restoration. The work has included the entire rebuilding of the south arcade, the thorough renovation of the chancel (only the side walls of which have been left standing), the re-flooring of chancel, nave, and aisles, and the re-roofing of the whole of the church with Memel timber. The east end wall—formerly of brick, with an ugly, unsuitable window—has been altogether rebuilt of stone, and the window is filled in with stained glass representing scenes in the life of our Lord. The north aisle has as yet been left comparatively untouched, and a considerable amount of alteration is required. The complete restoration was estimated to cost about £6,600, and of this sum the work already accomplished will amount to something like £5,400. Mr. G. E. Street, R.A., of London, has been the architect, and the contract was intrusted to Mr. H. Lovatt, of Wolverhampton.

CHANCERY LANE.—Mr. T. Searancke Archer, A.R.I.B.A., of 2, Gresham Buildings, E.C., is the architect of a Renaissance block of offices just erected at the corner of Chancery-lane and Southampton Buildings. The materials used in construction are red Suffolk brick, Portland and Box Ground stone, and the roof is covered with Eureka green slating. It is fitted up internally with specially designed wooden chimney pieces and Barnard's stoves, and ornamental lead lights have been used in all upper sashes over the segmental bars, and in panels of entrance doors and in transom. Advantage has been taken of the cellars under roadway to construct a number of fireproof strong rooms for the use of tenants. The builders were Messrs. Lloyd, and the carving was executed by Mr. Hearn.

CHESTER.—On Sunday a new altar dedicated to St. Joseph, was opened by the Bishop of Arundale in St. Francis' Catholic Church, Chester. It has been designed and made by Mr. John A. Hanley, of Grosvenor-road, Chester. The altar, which is of Storeton stone, is supported on red marble shafts and carved capitals. The central feature, and forming the altar-piece, is a statue of St. Joseph, on a carved pedestal, under a rich octagonal canopy supported on marble shafts, on either side of which are panels of delicate carvings, viz., the oak, lily, rose, and pomegranate, each having a typical reference to the Saint. A boldly-carved cornice terminates the altar; the general effect of the whole is heightened by the introduction of numerous marble shafts, and inlays of red and green colour.

CREWE.—The new Manchester and Liverpool District Bank, Crewe, was opened on Saturday week. It is partly in the Gothic and Elizabethan styles of architecture—a half-timber design peculiar to Cheshire, having gables and dormers. The upper portion of the building is of ornamental brick, mixed with woodwork. The building is chiefly of bricks with dressings of Alderley stone, and the roofs are covered with red tiles. The contractor is Mr. A. P. Cotterill, of Crewe; Mr. Beattie has been clerk of the works; Messrs. Barker and Ellis, of Manchester, are the architects. The cost of the building is between £4,000 and £5,000.

DERBY.—The new Free Library at Derby is completed. The cost has been over £15,000. Messrs. Woods, of Bolton, have been the contractors, and Messrs. Freeman and Naylor, also of Bolton, the architects. The design is Queen Anne, carried out in red brick with stone facings. The curator's house, built in harmony with the large building, is placed on the left-hand side of

the library. The libraries are placed in the centre of the building, and inclosed on two sides by a screen of stained glass. The libraries are lighted from the roof. The second floor gives access to the Sculpture Gallery. The Museum itself runs right round this second floor. The basement of the building includes the curator's workshops, together with the Library of Patent Specifications, the assistants' retiring-room, the binders' workrooms, and three storerooms.

DITTON.—The new Roman Catholic Church of St. Michael, Ditton, was opened on Thursday week. The building has been a very costly one, the total amount expended on its construction being between £17,000 and £20,000. The external walls consist of red local sandstone. Internally the material employed is chiefly French white stone. The length of the church from the sanctuary to the door is 120ft.; width of the transept 80ft., and width of the nave and aisle 60ft. The roof, which is of oak, is 60ft. high, while the height of the church in those parts where the oak roof stops short is 40ft. The oak roof is oval-shaped, and in its present plain and unembellished state naturally does not add to the appearance of the edifice. The style adopted throughout the building is Early Norman. The architect was Mr. Clutton, Burlington-street, London, the builder, Mr. Kimberley, of Oxford.

GOOLE.—The Goole Local Board have accepted the tender of Mr. Richard Elliott for the forming, making, metalling, channelling, draining, &c., of five new streets in Old Goole. The tenders were as follows:—Marsh, £1,545; Elliott, £1,550; Wilson, £1,995; Sherman, £2,215; the chief reason of Mr. Elliott's tender being accepted was understood to be that Mr. Elliott being a resident would employ the labour of the locality. The plans, specifications, scheme of drainage, &c., have been prepared by Mr. E. C. Buchanan Tudor, engineer and surveyor to the board, and under whose superintendence they will be carried out. At the last meeting of the board on the 6th inst., Mr. Tudor was requested to design a scheme of sewerage for Pasture and Marshfield-streets in New Goole.

KILBURN.—The new Roman Catholic Church of the Sacred Heart, Quex-road, Kilburn, was opened on Thursday week. The style is Early Decorated, and when completed the building will contain nave and aisles 90ft. by 51; chancel 45ft. by 33; north and south transepts 24ft. by 16; two chapels 25ft. by 12; a tower 16ft. square and 140ft. high. Four bays of the nave are now completed. The height of the church from floor to apex is 61ft. There is a gallery which occupies the first bay of the nave, and which is approached by a stone staircase corbelled out from the buttress at the west end. The materials are yellow malms, with Bath stone dressings. The nave arcade is supported by polished Bessbrook granite columns, with Portland stone capitals and bases. The roof, which is open to the apex, is open-timbered of pitch-pine, and covered with slates. The actual cost of the present portion of the church is £6,000, but the total sum required for its completion will be about £8,000. The architects are Messrs. Pugin, Ashlin, and Pugin. The works have been carried out by Messrs. Merrett and Ashby, of London Wall; the metal work being supplied by Messrs. Hardman.

METROPOLITAN BOARD OF WORKS.—At this board on Friday it was agreed to have a conference with the City Commissioners of Sewers with regard to the Metropolitan and Metropolitan District Railway Company's Bill for City lines and extensions. Amongst the dangerous structures to which works were ordered to be done by the board's contractors, Messrs. J. and J. Greenwood, was St. George the Martyr Church, Southwark. A letter was received from the Royal Institute of British Architects, stating that the council had granted certificates of competency to perform the duties of district surveyors to Messrs. P. Hunter, J. W. James, G. A. Lean, and A. T. Taylor. To the Works Committee was referred a communication from the Society for the Protection of Ancient Buildings, expressing their regret at the decision of the board to raise and open up the York Water Gate, setting forth their reasons why the gate should be preserved in its present position, and stating what works would, in their opinion, be desirable to carry out in connection with it.

OLNEY.—The corner-stone of the Cowper

Memorial Congregational Church, Olney, was laid on Friday. The style adopted is Thirteenth Century Gothic. In plan the church is rectangular, measuring 65ft. long by 38ft. broad. It consists of a nave and side aisles, with a clerestoried roof, which is carried by lofty stone piers at each side of the pulpit, and by iron columns in the nave. Provision is made for seating 328 in the ground floor, and 122 in an end gallery. The work will be carried out in a local limestone, with Bath stone dressings. The roofs will be slated, and the interior of the building plastered. The contract cost of the work is £2,129, the architect being Mr. John Sulman, A.R.I.B.A., Furnival's Inn, Holborn, London.

OSMASTON.—The picturesque little church of St. James, Osmaston-by-Derby, was reopened by the Lord Bishop of the Diocese, on Thursday last, after thorough restoration, from the designs of Mr. Frederic Augustus Devey, of York, by the builders, Messrs. Bullock and Barton, Melbourne, Derby. The flat ceilings of the nave and chancel have given place to open-timber roofs of pitch-pine. A new vestry is provided, chancel and other arches constructed, and arches which were found built up have been opened; four new windows, built in new positions, and filled in with memorial stained glass. The interior of the chancel walls has been faced with alabaster. The floor has been relaid with encaustic tile paving, and the old seats have been removed, and open sittings of pitch-pine substituted; a stone pulpit and open lectern, presented, and much is added to the pleasing appearance of this church by the very chaste altar cloth and fittings which are designed and worked by Mrs. Ussher, who is one of the principal contributors to the restoration.

THE LEYS SCHOOLS, CAMBRIDGE.—The new dining-hall and temporary dormitories in connection with the scheme are now complete, and the north block of houses which will form part of the permanent scheme (and which is one of three blocks forming a quadrangle) is progressing rapidly. The dining-hall is intended to accommodate 350 students. It is built of red brick with Ketton and Corsham stone dressings. It is Early Perpendicular in character, and the fine open-timbered roof is filled in with traceried spandrels. The north block of houses is intended to accommodate eighty students, besides masters' rooms, sick-rooms, visitors' rooms, bath-room, housekeeper's rooms, lavatories, &c.; the same character is of course observed in this as in the dining-hall. The total cost of the whole of the above, including temporary dormitories, is nearly £16,000. The architect is Mr. Robert Curwen, 23, South Castle-street, Liverpool; the clerk of works Mr. George Dalton; the builders have been: Mr. J. Denson, Cambridge, for dining, &c., and Messrs. Pattinson, of Sleaford, for the north block. The cost of the complete scheme is to be about £48,000.

TRURO CATHEDRAL.—A meeting of the general committee of the Truro Cathedral Fund was held in the Bishop's Library, Truro, on Tuesday. The principal business was to inspect the plans of Mr. J. L. Pearson for the proposed cathedral. The style is that of the early part of the Thirteenth Century, and there are to be a central and two western towers. The length from east to west is about 300ft. For the choir 115ft. is allowed, and for the nave 165ft. Mr. Pearson estimated the cost at £95,000, which, with £10,000 required for purchase of land, &c., gives a total to be raised of £105,000. The plans, which were in an unfinished state, owing to the illness of Mr. Pearson, were referred to the executive committee to examine and report upon to the general committee.

WATERBEACH, CAMBRIDGESHIRE.—The parish church of St. John the Evangelist, Waterbeach, was reopened last week, after having been restored at a cost of £3,000. The church was originally of the Early English style, but it was almost rebuilt during the Early Perpendicular period, and the north aisle and porch, the vestry, and organ-chamber just added have been designed in the latter style. The tower has been carefully restored. The new aisle is seated with oak benches, and the windows have been filled with richly-painted quarries. The whole of the floors of the church have been laid to an elaborate design in tiles, by Messrs. Maw and Co. A new reredos is placed at the east end of the church. It is constructed of richly-veined alabaster, and

is surmounted by a carved cross in which a jewel is inlaid. The arreading of the reredos stands upon shafts of Irish green marble, filled in with figures in Opus Sectile mosaic, representing, on the south side, David, Aaron, and Elijah, and on the north side, John the Baptist, Peter, and Paul. The caps of the shafts are of alabaster, richly carved. In the super-altar are three figures in mosaic, with gold background; the centre one represents the Lord seated in glory, and on either side are the Evangelist St. John and Mary Magdalene in adoration. A new oak Communion-table has been carved by Messrs. Rattle and Kett, of Cambridge; it is chiefly composed of cut tracery oak panels from the old screen, rearranged and framed; upon it has been placed an old Purbeck marble slab, which was found in pieces in the church, part being buried under a Tudor floor in the sacarium. New sedilia, piscina, and credence of alabaster have been placed in the chancel, and a new sacarium floor laid down, formed of polished black and white marble, with solid marble steps. The new pulpit is of alabaster and coloured marbles, with figures of Elijah and John the Baptist in niches. The works have been carried out under the direction of Mr. J. Ladds, of Bedford-row, London, by the contractors, Messrs. Warboys, of Basingbourne, and W. Whitehead, of Royston. The carving has been carried out by Mr. E. Whitehead, of Clapham, S.W., the mosaic by Messrs. Powell and Son, of Whitefriars, London, the glazing by Mr. Holmes, of Robert-street, Grosvenor-square, and the brass standards, locks, and wrought-iron hinges by Messrs. Richardson, Ellison and Co., of Holborn. The Creed, Lord's Prayer, and Commandments, are executed in tiles, designed and hand-painted by Mr. Constable, of Cambridge.

WATH-UPON-DEARNE.—A new Roman Catholic church, dedicated to St. Joseph, at Wath-upon-Deerne, was opened on the 1st inst. The design of the church has been studied from the old churches of the district erected at the close of the Fifteenth Century, and is of the Late Rectilinear period. A flèche or spirelet of stone marks the division between nave and chancel, and rises to a height of 70ft., and in it are hung two bells. A porch, with a niche and figure of St. Joseph, holding in his arms the Infant Saviour, is a feature of the front. The interior consists of a nave 61ft. by 24ft., and a chancel 24ft. long, with an organ chamber placed on the north side. The chancel arch affords a view of the eastern window of five lights, containing in the centre the Crucifixion, with figures of the Blessed Virgin and St. John, the remaining four lights containing figures of St. Augustine, St. John of Beverley, St. Ann, and St. Mary Magdalen. The glass is, with the two side windows, from the firm of Lavers, Barraud, and Westlake. There is a pavement of Goodwin's encaustic tiles in the chancel, and the floor of the nave is laid with blue and red Staffordshire quarries. The architects were Messrs. Hadfield and Son, of Sheffield.

An inquiry was held at the Town Hall, Hove, on Thursday in last week, before Col. Ponsonby Cox, Inspector to the Local Government Board, with reference to the proposed borrowing of £30,000, for the erection of a new Town Hall, at Hove; and an additional £550 for sewerage works. Considerable opposition was raised to the former proposal, on the ground that the present building is large enough for municipal purposes, and that the proposed expenditure of £3,500 on a Town Hall, for a population of 17,000 was extravagant.

The parish church of Stockton, Wilts, is in course of enlargement and restoration. The works going forward include the removal of an unsightly gallery, the strengthening of the tower, taking down east wall of south aisle, and part of south wall of chancel, to allow of the erection of organ-chamber, enlargement of north aisle, addition of vestry, and the repairing, re-seating, and warming of the church. The estimated cost is £1,900.

After being in hand over five years, the Bristol and Portishead Docks, constructed at the cost of £280,000, on the Somersetshire side of the mouth of the Avon at Bristol, have been completed, and water has been let in to the depth of 22ft. The total depth will be from 25ft. to 30ft. The main dock is 1,800ft. long by 500ft. wide.

The Vestry of Bermondsey decided, on Monday week, to purchase land in Tranton-road, Blue Anchor-road, upon which to erect a vestry-hall, public hall, library, and stoneyard.

More than Fifty Thousand Replies and Letters on subjects of Universal Interest have appeared during the last ten years in the **ENGLISH MECHANIC AND WORLD OF SCIENCE**, most of them from the pens of the leading scientific and technical authorities of the day. Thousands of original articles and scientific papers, and countless receipts and wrinkles embracing almost every subject on which it is possible to desire information have also appeared during the same period. The earliest and most accurate information respecting all new scientific discoveries and mechanical inventions is to be found in its pages, and its large circulation renders it the best medium for all advertisers who wish their announcements to be brought under the notice of manufacturers, mechanics, scientific workers, and amateurs. Price Two-pence, of all booksellers and news-vendors. Post free 2jd. Office: 31, Tavistock street, Covent-garden W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 33fr. 30c.). To India (via Southampton), £1 6s. 6d. To any of the Australian Colonies New Zealand, the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

N.B.—American and Belgian subscribers are requested to remit their subscriptions by International P.O.O., and to advise the publisher of the date and amount of their remittance.

If the last-mentioned precaution is omitted some difficulty is very likely to arise in obtaining the amount. Back numbers can only be sent at the rate of 7d. each, the postage charged being 3d. per copy. All foreign subscriptions, unaccompanied by an additional remittance to cover the extra cost of forwarding back numbers, are commenced from the next number published after the receipt of the subscription.

Cases for binding the half-yearly volumes, 2s. each.

RECEIVED.—C. and Co.—F. G. M.—D. R.—M. Bros. and Co.—D. R. R.—W. and Co.—H. R. S. A.—B. of A.—C. M.—L. T.

W. G. O. (It is scarcely necessary to say that reviews of competition designs are never written by interested persons.)—R. T. P. (Any respectable patent agent will search for you.)

"BUILDING NEWS" DESIGNING CLUB.

"POORHOOD." (This design came too late; the plan is suitable, but the entrances and seating are defective.) In the designs for chimney corner we have received a very good design under "Motto J.," but it was received too late for our review.

Correspondence.

IPSWICH POST-OFFICE COMPETITION.

To the Editor of the BUILDING NEWS.

SIR,—The treatment to which architects are continually subject at the hands of building committees is, of course, only too well known; indeed, comments on the subject have almost developed into mere truisms, whose insipidity results from one's habitual familiarity with the fact. There is, however, a freshness about the instances as they occur in "the old, old tale," especially when the discussions and proposals of competition committees are made known. Each seems to vie with the other in unfair and unbusiness-like proposals, such as the members individually would of course repudiate at once in their own commercial dealings as unworthy of consideration. That such proposals are made in ignorance cannot be allowed while the principles of morality are worth naming, and, indeed, no one not devoid of common sense would ever think of treating lawyers or any other body of professional men in the way in which architects are dealt with. The instance of this sort of thing to which I would draw your attention is recorded in last Saturday's *Southfolk Chronicle*, where the discussion of the Town Council of Ipswich on the election of a professional referee is given in full. Fortunately, by a majority of 12 to 7, the competitors have escaped the iniquitous proposal of Mr. W. Fraser, who said that the architects engaged in the competition would willingly forego any premium if the Council determined to consult the President of

the R.I.B.A., Mr. Charles Barry, with reference to its award. So that, according to this successful cloth-merchant of Ipswich, the premium of 50 guineas offered by the Council for the best design would be economically blended into the probable fee of one hundred guineas, to be paid to the referee for his services in helping them to arrive at a decision. Sixty guineas, with ten guineas a day expenses, said the Mayor, who had been in communication with Mr. Barry, would be the terms for adjudicating upon the plans. Thus one hundred pounds would be paid to award fifty, which sum was to return to those who gave it, while the twenty-two architects, who together have spent about six hundred and sixty pounds in preparing their designs, would simply have the satisfaction secured to them by the original condition, that no guarantee is given that the selected design will be executed, at any rate, under the supervision of its author, although, mark you, in the words of the Ipswich "Conditions for architects," "The whole of the designs, reports, drawings, specifications, &c., are to become the property of the Corporation." Oh you cloth-merchants, butchers, bakers, tailors and tinkers of Ipswich, where is your sense of justice? These twenty-two architects have responded to some offer made them, "not wisely, but too well." Foolish they may be to spend so much to gain so little; but surely, in all common fairness, let them be treated with something like justice, and as Mr. Barry has been elected to report upon the plans, let us hope that the most suitable design will be selected, though few, probably, who hear the above particulars can readily believe that it will. I am not a competitor, but

AN OLD T. SQUARE.

THE RAMSGATE NEW ROAD COMPETITION.

SIR,—As yours is the only journal that has taken the trouble to make any notes on the plans submitted in competition for the Ramsgate new road, I address myself to you to show by one more example what professional men must expect if they are so unwise as to be competitors for public work in open competitions.

The conditions issued by the commissioners were drawn up by a well-known London engineer in conjunction with the town clerk. They were fair, explicit, and still more, showed what was passing in the minds of the commissioners at the time the conditions were issued. Most of the plans submitted have, I believe, complied with the conditions, excepting those which follow a similar line to that which Mr. Abernethy has considered of such merit as to have earned the first premium. The expressed intention of the commissioners was that they had determined the new road should be kept as much as possible to the front, and of such importance did they consider this that they went out of their way to state that the Custom-house and pier stores could be acquired from the Board of Trade without difficulty. Here was the clear direction of the promoters. Mark the award of their professional assessor! The first premium is given to the plan of all others that keeps in the background, and comes no more to the front than can possibly be helped. I have no desire to say we work against Mr. Abernethy—as an engineer; but he is human, and errs, like most other human beings; he has erred before, if we are to believe the Ramsgate people, on a matter of sewerage connected with the sea outfall; he has erred for a second time, and done a gross injustice to those gentlemen who have stood by the conditions laid down by Mr. Abernethy's employers. The plan this gentleman has chosen, if executed, would further a pet scheme for a railway from Ramsgate to Deal, in which he avows he has a personal interest. Plainly then, is it honest and fair to employ a gentleman who has a grain of interest in the locality in future engineering schemes—as an arbitrator? I believe the commissioners were desirous of employing some one who would give a just award.

I have not seen the designs, and therefore may be incompetent to criticise them, which I do not desire, but if the printed description of the first premiated plan is correct, it is nothing more or less than that designed by Mr. Ellise Clark seven years ago, a cartoon of which hung for years in the Town Hall; a plan made anterior to Mr. Abernethy's pet railway deposit, and follows, with a few alterations, a route that would enable the latter gentleman's railway to be carried underneath. It would appear that

the assessor made the new road subservient to his Parliamentary plans, as near as could be, never hinted at in the conditions, and he ignored the expressed intentions of the Commissioners.

Let us hope the Ramsgate authorities have wisdom enough to set aside the award of this interested gentleman, and that they will carry out a scheme giving that which they advertised for—a marine drive connecting the cliffs and town.—I am, &c.,

AN ENGINEER WHO DID NOT COMPETE.
London, S.W., May 10, 1879.

LISKEARD SCHOOL BOARD COMPETITION.

SIR,—Will you kindly insert the inclosed letter from the *Western Morning News* in your next issue? I am as well add that the successful competitor has agreed to carry out these schools, and also others for eighty children for £20, instead of his 5 per cent. commission; and before accepting his design the Board wrote and asked him if he had included boundary-walls in his estimate; he wrote and said "Yes." In the competition specification *Aberthaw line* was specified, but on the ones given to builders to tender from *common line* was substituted. When such things are done by professional men, we may well despair of ever having competitions on a fair footing.—I am, &c., A COMPETITOR.

[COPY.]

"LISKEARD SCHOOL BOARD."

"SIR,—Architects having been invited to submit plans and specifications, with estimates of cost of erection and completion, for a school and master's residence at Trewidland, including boundary walls, the Board received plans, &c., from the following gentlemen, viz.:—Mr. Vincent, estimated cost, £909; Mr. Elliott, £850; Mr. Wise, £850; Mr. Treval, £750; Mr. Clifton, £638; Mr. Skentlebury, £500, and decided on adopting Mr. Skentlebury's plans, &c., on the ground of cheapness, after being assured by that gentleman that the work could be carried out for the sum named by him—£500—and that the price was not founded on his own opinion only, but that he had consulted a builder in the matter also.

"In response to an advertisement several tenders for the work were received, the lowest, that of Mr. Whale, of Altermum, being accepted—£504—being in advance of the architect's estimate £94. The next lowest tender was that of Mr. Trehan, of Liskeard, £700, or £200 in advance of the architect's price. The Board met on Tuesday last to make the necessary arrangements with the contractor, when that gentleman asked to be allowed to alter his price to £659 on the ground that he had omitted the boundary walls in his first tender. A discussion ensued as to whether it would not be advisable to throw overboard Mr. Whale's tender and accept the next lowest. It was, however, ultimately decided to add £65 to Mr. Whale's tender and allow him to do the work. A large number of ratepayers feel aggrieved at the course adopted by the Board for the following reasons, viz.:—

"1. Mr. Skentlebury's plans having been selected, on the ground of cheapness—£500 for the entire work—that gentleman ought to have been called upon to carry out the same, in fairness to other architects, or his plans thrown overboard.

"2. Mr. Whale's tender being also accepted on the same grounds, he should have been called upon to carry out the work at the price first named, or to give it up.

"3. They can have little confidence in the satisfactory completion of the work after so much evidence of bungling on the part of the principals.

"A gentleman who was absent from the meeting when this important business was put to the vote is anxiously inquired for.—Yours truly,

"A RATEPAYER."

CHURCH RESTORATION IN THE TIME OF GEORGE THE FOURTH.

SIR,—The following cutting, clipped from an Exeter newspaper, under date of October 6, 1825, is interesting, in that it has reference to church restoration of that date:—

"The roof of the parish church of St. Stephen in this city being much out of repair, the parishioners have, with laudable zeal, determined to take the opportunity for remodelling and beautifying the interior, by which it will be rendered light and airy, as well as more commodious than at present. The old roof is to come down entirely, and to give place to two rows of light pillars and arches, dividing the church into a centre and two side aisles; the effect of the whole will be to render it one of the handsomest parish churches in the city. The

present building was erected on the site of the old church in 1664, with the exception of the tower, which received some additions to the upper part a few years since, but is otherwise most probably coeval with the original building."

St. Stephen's is situated in the High-street, and is known locally (on account of a small street running at right angles to the main thoroughfare, going directly under the chancel) as St. Stephen's Bow. Its exterior continues to be "restored" every few years by receiving a good coat of paint, equally put on from wall-plate to plinth. Indeed, curious to record, whilst so many of our outlying Devonshire churches have their requirements carefully and lovingly attended to, the reverse is the case with the score or so of old ones to be found in the "ever-faithful" city. These, with one or two notable exceptions, rarely receive more attention than a bucketful of whitewash is capable of bestowing.—I am, &c., HARRY HEMS.

Exeter, May 12, 1879.

CARLIOL TOWER, NEWCASTLE.

SIR,—Whatever it may be to the ratepayers of Newcastle, I am inclined to think that the "washing out" of any portion of the "dirty linen" from the Borough Engineer's Office, will be but of little interest to the general body of your readers. For this reason I will not presume to occupy your valuable space by going over the whole of the controversy raised by the proposed destruction of the Carloli Tower or Weavers' Hall. But, perhaps, I may be allowed to say that, having had an opportunity of reading the reports of the Government Inquiry, published in the Newcastle papers, I find that those reports, to all intents and purposes, coincide with your own. Mr. Fowler quietly accepts the reports published in his own district, where all the details of the controversy are well known; but, taking advantage of the fact that the vast majority of your readers are totally unacquainted with the subject, he thrusts upon us the tittle-tattle of a petty quibble between Mr. Oliver and himself. In following this course of action, Mr. A. M. Fowler exercises a very wise discretion. He puts himself to a great deal of unnecessary trouble in pointing out with much minuteness a mistake in Mr. Oliver's sketches as to the proper position of the Carloli Tower. I say unnecessary trouble, because this self-same mistake was pointed out in the public press eight or nine months ago, and acknowledged also in the press by Mr. Oliver at the same time. It was again pointed out by Mr. Oliver himself at the Government Inquiry, and he explained, at the same time, how it could be overcome. This error, then, having been pointed out and explained again and again to the public during the last nine months, Mr. Fowler in the "rich plenitude of his generosity," again kindly explains for the edification of your readers, and upon the strength of this somewhat mistaken act of kindness, and in defiance of all the rules of English grammar, he asks us to pass an opinion as to whether such "grave errors can be considered clerical?" Mr. Fowler lays himself open to a personal retort, of which I will not take any advantage; but I leave it to those inhabitants of Newcastle, who, from their knowledge of this matter, are best able to judge, to say whether Mr. Fowler is thus justified in throwing dust into the eyes of the public, and blinding them to the merits of the real question at issue, viz., whether Mr. Fowler and the Town Council shall or shall not be permitted, without the shadow of a shade of reason, to ruthlessly destroy one of the most interesting features of the Northern metropolis.—I am, &c., AN OLD NOVOCASTRIAN.

MR. STATHAM'S ROYAL INSTITUTION LECTURES.

SIR,—I am reading with great interest these excellent lectures; but I am sorry to say that I have come across one or two stumbling-blocks. For instance, Mr. Statham says, "the Corinthian order is more correctly regarded as a Roman than as a Greek order, for it was but rarely used by Greek architects;" but, he says again, "On comparing the order as developed in Rome with that of Greece, a very important difference was apparent, and one which in principle distinguished the art of the two nations in every feature"—showing that the Greek Corinthian had at least so much individuality that it "very im-

portantly differed" from the Roman. I have always understood that the Corinthian of the Choragic Monument of Lysierates is as thoroughly Greek as is the Doric of the Parthenon. Again, in speaking of the Ionic order, Mr. Statham says, "in Greece Ionic columns were only employed between pilasters," and that "the Romans used the Ionic columns at angles, and without pilasters, the consequence being that the volutes did not present an agreeable appearance when viewed sideways." I have hitherto been under the impression that this same disagreeable appearance when viewed sideways was to be found in one of the Greek Ionic temples grouped upon the Acropolis of Athens.

If I am in error, perhaps Mr. Statham, or some other authority, may do me the kindness to put me right.—I am, &c.,

A PROVINCIAL PRACTITIONER.

Intercommunication.

QUESTIONS.

[5763].—**Wood Pavement.**—Will any of my fellow-readers kindly inform me of the best way to lay a wood pavement for ordinary traffic?—K.

[5764].—**Sizes of Rooms on Plans.**—I should be glad of the opinion of some practical correspondent on the following point:—Are the sizes of rooms figured on plans to be considered as meaning when the plaster is on and the rooms finished, or from the wall or brickwork itself? The proprietor says the former.—SET SQUARE.

[5765].—**Art Exhibition at Swansea.**—Can any reader give any further particulars respecting the Art Exhibition at Swansea, to be held, according to a "chip" on p. 505 in your last issue, in October next? I fancy the announcement is a mistake. I know the Church Congress this year was to have been held at Swansea, but I believe it has been decided not to go there. I have not heard of any other exhibition.—WOLFE EXHIBITOR.

[5766].—**Purification of Sewage.**—I will be glad if one or more of your experienced correspondents would give me particulars of all that is required to be done in order to secure the sewage of a village (inland) being rendered pure before being let into the village stream, and such as will meet the requirements of the "Rivers Pollution Act, 1875." The population is 8,000, and the locality a poor one. It is desirable, of course, to have the arrangements as simple as can be commensurate with a rendering of the sewage harmless to the stream.—LOCAL SURVEYOR.

[5767].—**Purpose-Made Bricks.**—Will one of your readers give me some information as to the precise object gained by the use of bricks purposely made for the erection of a building? I noticed in the description given last week in the *BUILDING NEWS* of the new Divinity Schools at Cambridge, that bricks had been made to work four courses in gins, and I think purpose-made bricks have been used by Mr. Street in the New Law Courts. Is the expense of building much increased by this practice?—L. T. W.

[5768].—**Mechanics.**—Will some obliging reader inform me of the simplest rudimentary work known on mechanics applied to building construction, and also a simple work on the science of Gothic vaulting?—LIONEL.

[5769].—**Marble.**—I have got a lot of marble which I want cut into pieces and polished. Any information regarding the above would much oblige.—AMATEUR.

REPLIES.

[5716].—**Imperial Hotel, Torquay.**—This hotel, one of the finest and perhaps the very best situated places of the sort in the West of England, was built in two sections. It has a frontage of 120ft., by 90ft. deep. I forget the architect's name, but the second half was built by Mr. James Matcham, of The Crescent, Plymouth, who I am sure would be glad to give "J. A. C." any further particulars he may wish to know.—HARRY HEMS.

[5724].—**Queen Anne Buildings.**—Mr. H. Barnes will find by reference to back numbers of the *BUILDING NEWS* that most of the best examples of this class of work have been illustrated therein within the last four or five years.—HARRY HEMS.

[5728].—**Coloured Building Stone.**—Having given much attention to building stone for many years, I have naturally felt some interest in the correspondence upon this subject which has appeared in your columns, and I regret not to find in your last edition a distinct answer to "J. W.'s" question of the 2nd inst., prefaced as it is by such high commendation of the "Hand in Hand." The general impression has been that the stone in question is "Corsehill," and I was myself so struck with the effective appearance of the stone that I directed the attention of an architect to it, who has since used "Corsehill" for some mansions which he has erected in Cromwell-road, Kensington, and which, I think, equally deserve to be commended, the stone in the latter work carrying as fine an air, and holding its colour equally as well as that in the first-named building. There cannot be a doubt Mr. Trickett is able to inform your readers where the stone really comes from and what its real name is, and I trust he will do so. In my turn should also be glad to know what the stone is at Gloucester-road bridge.—G. F.

[5728].—**Coloured Building Stone.**—I have noticed that for some weeks past a correspondence has been kept up with reference to coloured building stone, and that "G. H. G." in alluding in his last week's communication to the red Mansfield stone used at St. Pancras Hotel, states that the darkest variety of this stone has shown itself to be the most durable. I suspect that "G. H. G." knowing that red Mansfield stone was rather

extensively used in this building, has taken it for granted that all the red stone that is therein to be seen came from Mansfield, whereas the fact is that several sorts were used, the darkest and most durable of all coming from Duffries and neighbourhood. As the execution of the whole of the works involved in the erection of the building in question was under my personal supervision, I frequently had occasion to visit quarries and examine the respective qualities of the different stones, and in the case of red Mansfield avoided selecting the darker variety, as I knew, from many years' experience, its inferiority in point of durability.—JOHN SAVILLE.

[5740].—**English, French, and German Architectural Dictionary.**—As "Corvus" has had no reply to his question, perhaps it may be of some use to him to know that a vocabulary of architectural terms in 8 different languages was published in two numbers of the *Builder* for April, 1864, originally compiled, I believe, by the Board of Works.—W. J. N.

[5745].—**Wood Roofs.**—In my last reply the figures "295" and "294" and the consequent 42in. must have been inadvertently mistranscribed from my calculation paper, but the right number, 324, gives 5in. in the place of 43, and then by reducing the allowance for notching, &c., to 4in. \times 1in., we obtain the same scantling as before, viz., 6in. \times 4in. I had, I believe, originally obtained 6 \times 4 on the scribbling paper, and hence the reason the mistake escaped me. "Nil Desperandum" asks me to give detailed workings for the various parts, assuming certain strains to be on those parts. In my first letter I asserted that with respect to the timbers in tension the usual scantling is so very much in excess of the sufficient strength of the timber that calculating according to the strain in tension is of no moment, because if we were so to reduce them they would then otherwise be too weak, and I enumerated several contingencies in support of this, and it should be recollected that tie-beams frequently are made to perform heavy duties, and rough usage from possible falling of pieces of timber, &c., quite enough to break them or split them if weak, during the progress of the works. With respect to the principal rafters, even those are made much in excess of the strain that is on them, because if both the purlin and the principal rafter be notched the double notching so locks them together that the rafters are practically confined on both sides and underneath by the strut and on the top will be the pressure of the roof covering, and so practically the principal rafters also require to be considered as requiring substance in scantling, principally for the purpose of solidity and to provide against unexpected defects in the timber and which so frequently exist, notwithstanding all efforts to insure timber free from knots. The formula $W = 20 \frac{b^3}{l^3}$ is derived as follows:— W is equal to the safe load in cwt. or otherwise the load which will really resolve itself in a line with the axis of the principal rafter = W , and is just equal to the resolution of the weight of the roof timbers and covering. Now near enough for practice in ordinary cases half the weight of roof and covering will be on the walls, and the remaining half will be in compression on the principal rafters; but the resolution of forces may be said to double this half, hence the whole weight of the roof may be considered as the resolved pressure on the two principals, hence half the weight of the whole roof taken both sides of ridge will be the resolved pressure on the end of one principal rafter, and if we assume the trusses 10ft. apart, and the roof and covering to weigh half a ton per square, we shall have, say, 1cwt. per foot lineal of common rafter as the resolved pressure on the principal rafter underneath, then the constant 20 is equal to the assumed crushing load on an inch cube of fir, then $\frac{b^3}{l^3}$. Now for the

present let us consider that the whole of the above are in inches, then if the strength of timber in compression were to increase only as its length, and if b were = l we should have $\frac{b^3}{l^3}$, varying as the weight, when l increased b , also l would increase in the same ratio, and which would also give us $\frac{b^3}{l^3}$, as since $b = l$ also must $b^3 = l^3$. In the above, as l^3 increases in direct ratio to the length, it is manifest that its root l cannot increase in proportion to the length, and which could easily be demonstrated. But the strength increases as the square of the length, and therefore we must once more involve l , whence we have $\frac{b^3}{l^3}$. We now make l into feet, which gives us twelve times the crushing strength, l^3 remaining the same, and we now square l and multiply l^3 by b , which counterpoises same. And thus is our formula balanced and ready for use. I do not claim its discovery, but think it is fairly useful. Let us take an example of a roof of 40ft. span. Let its slope be = 25ft., then we say we shall have a resolved pressure of 25cwt. = W on principal, then $25 = 20 \frac{b^3}{l^3}$ $25 = 20 \frac{b^3}{1600}$ $\therefore 1 = \frac{20 b^3}{1600}$ $1 = \frac{20 b^3}{40000}$ and $40000 \div 20 = 2000 \therefore 1 = \frac{b^3}{2000}$ Let $b = 6$, then $6^3 = 216$, and $2000 \div 216$ give 9 nearly \therefore say, 9 \times 6, but as the purlins must so the same less might very well do. Whether queen posts or king posts be used, the strain on principals must be the same. Tie-beam = $\frac{120 \times 2}{3} = 80$, say, 12 \times 7. King-post if used

would only have about half the strain the tie-beam has, and $\frac{1}{2} \times 80$ would do. Struts are only auxiliaries to help support the weakest part of the principal, and if not half the area the principal they support would give them equal strength \therefore about 26in., but taking for area 4 in their length in inches could not fail to give strength enough. Straining beams between queens should be tied into short lengths or increased in sectional area accordingly. The principal rafter we have taken has been supposed to be for a king-post truss 40ft. span. If we were to have a king-post truss 60ft. span, we should, by our formula, obtain a much larger sectional area, being in the duplicate ratio due to the increased length of the rafter and to the corresponding increase of weight included in W , and being in direct ratio to the increase of the span. Now, if we obtain in a queen-post truss of 60ft. span a principal rafter equal in length to our principal rafter in the king-post truss of 40ft. span, the former will exceed the latter in sectional area in the ratio of 60 to 40, or of 3 to 2, and such is provided for in the formula, because when we wish to reduce the side of the equation containing W to unity, we multiply the denominator of the fractional side of the equation

by the integral number representing W , which still leaves both sides equal, whence the fractional side being now equal to one, the numerator, consisting of $20 \times b \times l^3$ must have such numbers assigned to b and l as will cause $20 \times b \times l^3$ to equal the denominator, and which consists now of length in feet, squared by the integral number of which W was composed, and the equation when solved really represents $1 = \frac{1}{1}$ whence, if we write it thus, $a =$

$\frac{z}{y}$ it will be evident that if a increases then y and consequently x will increase in exactly the same ratio, also if a diminishes so will y and x diminish in like ratio, and if we write the equation $a = \frac{wxy}{z}$, then if a increases likewise must z increase, and a similar increase must take place in wxy , and to effect which the altered value may be made in w or in x or in y , because, let a, w, x, y, z , be each equal to 1, then if a becomes 2 then x will become 2, and (wxy) now = 1 must become 2, and which will be effected if either w, x , or y be made 2, whence $2 = \frac{1 \times 1 \times 2}{1} = 1$, whence
